Chapter 1
Systems of Measurement

Conceptual Problems

***1 •**

Determine the Concept The fundamental physical quantities in the SI system include mass, length, and time. Force, being the product of mass and acceleration, is not a fundamental quantity. $\boxed{(c)\text{ is correct.}}$

2 •

Picture the Problem We can express and simplify the ratio of m/s to m/s^2 to determine the final units.

Express and simplify the ratio of m/s to m/s^2:

$$\frac{\frac{\text{m}}{\text{s}}}{\frac{\text{m}}{\text{s}^2}} = \frac{\text{m}\cdot\text{s}^2}{\text{m}\cdot\text{s}} = \text{s and } \boxed{(d)\text{ is correct.}}$$

3 •

Determine the Concept Consulting Table 1-1 we note that the prefix giga means 10^9. $\boxed{(c)\text{ is correct.}}$

4 •

Determine the Concept Consulting Table 1-1 we note that the prefix mega means 10^6. $\boxed{(d)\text{ is correct.}}$

***5 •**

Determine the Concept Consulting Table 1-1 we note that the prefix pico means 10^{-12}. $\boxed{(a)\text{ is correct.}}$

6 •

Determine the Concept Counting from left to right and ignoring zeros to the left of the first nonzero digit, the last significant figure is the first digit that is in doubt. Applying this criterion, the three zeros after the decimal point are not significant figures, but the last zero is significant. Hence, there are four significant figures in this number. $\boxed{(c)\text{ is correct.}}$

7 •

Determine the Concept Counting from left to right, the last significant figure is the first digit that is in doubt. Applying this criterion, there are six significant figures in this number. $\boxed{(e)\text{ is correct.}}$

8 •

Determine the Concept The advantage is that the length measure is always with you. The disadvantage is that arm lengths are not uniform; if you wish to purchase a board of ″two arm lengths″ it may be longer or shorter than you wish, or else you may have to physically go to the lumberyard to use your own arm as a measure of length.

9 •

(*a*) True. You cannot add ″apples to oranges″ or a length (distance traveled) to a volume (liters of milk).

(*b*) False. The distance traveled is the product of speed (length/time) multiplied by the time of travel (time).

(*c*) True. Multiplying by any conversion factor is equivalent to multiplying by 1. Doing so does not change the value of a quantity; it changes its units.

Estimation and Approximation

***10** ••

Picture the Problem Because θ is small, we can approximate it by $\theta \approx D/r_m$ provided that it is in radian measure. We can solve this relationship for the diameter of the moon.

Express the moon's diameter D in terms of the angle it subtends at the earth θ and the earth-moon distance r_m:

$$D = \theta r_m$$

Find θ in radians:

$$\theta = 0.524° \times \frac{2\pi\,\text{rad}}{360°} = 0.00915\,\text{rad}$$

Substitute and evaluate D:

$$D = (0.00915\,\text{rad})(384\,\text{Mm}) = \boxed{3.51 \times 10^6\,\text{m}}$$

***11 ••**

Picture the Problem We'll assume that the sun is made up entirely of hydrogen. Then we can relate the mass of the sun to the number of hydrogen atoms and the mass of each.

Express the mass of the sun M_S as the product of the number of hydrogen atoms N_H and the mass of each atom M_H:

$$M_S = N_H M_H$$

Solve for N_H:

$$N_H = \frac{M_S}{M_H}$$

Substitute numerical values and evaluate N_H:

$$N_H = \frac{1.99\times10^{30}\ \text{kg}}{1.67\times10^{-27}\ \text{kg}} = \boxed{1.19\times10^{57}}$$

12 ••

Picture the Problem Let P represent the population of the United States, r the rate of consumption and N the number of aluminum cans used annually. The population of the United States is roughly 3×10^8 people. Let's assume that, on average, each person drinks one can of soft drink every day. The mass of a soft-drink can is approximately 1.8×10^{-2} kg.

(*a*) Express the number of cans N used annually in terms of the daily rate of consumption of soft drinks r and the population P:

$$N = rP\Delta t$$

Substitute numerical values and approximate N:

$$N = \left(\frac{1\,\text{can}}{\text{person}\cdot\text{d}}\right)\left(3\times10^8\ \text{people}\right)\times\left(1\,\text{y}\right)\left(365.24\,\frac{\text{d}}{\text{y}}\right) \approx \boxed{10^{11}\ \text{cans}}$$

(*b*) Express the total mass of aluminum used per year for soft drink cans M as a function of the number of cans consumed and the mass m per can:

$$M = Nm$$

Substitute numerical values and evaluate M:

$$M = \left(10^{11}\ \text{cans/y}\right)\left(1.8\times10^{-2}\ \text{kg/can}\right) \approx \boxed{2\times10^{9}\ \text{kg/y}}$$

(c) Express the value of the aluminum as the product of M and the value at recycling centers:

$$\begin{aligned}\text{Value} &= (\$1/\text{kg})M \\ &= (\$1/\text{kg})\left(2\times10^{9}\ \text{kg/y}\right) \\ &= \$2\times10^{9}/\text{y} \\ &= \boxed{2\ \text{billion dollars/y}}\end{aligned}$$

13 ••

Picture the Problem We can estimate the number of words in *Encyclopedia Britannica* by counting the number of volumes, estimating the average number of pages per volume, estimating the number of words per page, and finding the product of these measurements and estimates. Doing so in *Encyclopedia Britannica* leads to an estimate of approximately 200 million for the number of words. If we assume an average word length of five letters, then our estimate of the number of letters in *Encyclopedia Britannica* becomes 10^9.

(a) Relate the area available for one letter s^2 and the number of letters N to be written on the pinhead to the area of the pinhead:

$Ns^2 = \frac{\pi}{4}d^2$ where d is the diameter of the pinhead.

Solve for s to obtain:

$$s = \sqrt{\frac{\pi d^2}{4N}}$$

Substitute numerical values and evaluate s:

$$s = \sqrt{\frac{\pi\left[\left(\tfrac{1}{16}\ \text{in}\right)\left(2.54\ \frac{\text{cm}}{\text{in}}\right)\right]^2}{4\left(10^9\right)}} \approx \boxed{10^{-8}\ \text{m}}$$

(b) Express the number of atoms per letter n in terms of s and the atomic spacing in a metal d_{atomic}:

$$n = \frac{s}{d_{\text{atomic}}}$$

Substitute numerical values and evaluate n:

$$n = \frac{10^{-8}\ \text{m}}{5\times10^{-10}\ \text{atoms/m}} \approx \boxed{20\ \text{atoms}}$$

***14** ••

Picture the Problem The population of the United States is roughly 3×10^8 people. Assuming that the average family has four people, with an average of two cars per family, there are about 1.5×10^8 cars in the United States. If we double that number to include trucks, cabs, etc., we have 3×10^8 vehicles. Let's assume that each vehicle uses, on average, about 12 gallons of gasoline per week.

(*a*) Find the daily consumption of gasoline *G*:

$$G = \left(3\times10^8\text{ vehicles}\right)\left(2\text{ gal/d}\right) = 6\times10^8\text{ gal/d}$$

Assuming a price per gallon P = \$1.50, find the daily cost *C* of gasoline:

$$C = GP = \left(6\times10^8\text{ gal/d}\right)\left(\$1.50/\text{gal}\right) = \$9\times10^8/\text{d} \approx \boxed{\$1\text{ billion dollars/d}}$$

(*b*) Relate the number of barrels *N* of crude oil required annually to the yearly consumption of gasoline *Y* and the number of gallons of gasoline *n* that can be made from one barrel of crude oil:

$$N = \frac{Y}{n} = \frac{G\Delta t}{n}$$

Substitute numerical values and estimate *N*:

$$N = \frac{\left(6\times10^8\text{ gal/d}\right)\left(365.24\text{ d/y}\right)}{19.4\text{ gal/barrel}} \approx \boxed{10^{10}\text{ barrels/y}}$$

15 ••

Picture the Problem We'll assume a population of 300 million (fairly accurate as of September, 2002) and a life expectancy of 76 y. We'll also assume that a diaper has a volume of about half a liter. In (*c*) we'll assume the disposal site is a rectangular hole in the ground and use the formula for the volume of such an opening to estimate the surface area required.

(*a*) Express the total number *N* of disposable diapers used in the United States per year in terms of the number of children *n* in diapers and the number of diapers *D* used by each child in 2.5 y:

$$N = nD$$

Use the daily consumption, the number of days in a year, and the estimated length of time a child is in diapers to estimate the number of diapers *D* required per child:

$$D = \frac{3\text{diapers}}{\text{d}}\times\frac{365.24\text{ d}}{\text{y}}\times2.5\text{ y} \approx 3\times10^3\text{ diapers/child}$$

Use the assumed life expectancy to estimate the number of children n in diapers:

$$n = \left(\frac{2.5\,\text{y}}{76\,\text{y}}\right)\left(300 \times 10^6 \text{ children}\right) \approx 10^7 \text{ children}$$

Substitute to obtain:

$$N = \left(10^7 \text{ children}\right) \times \left(3 \times 10^3 \text{ diapers/child}\right) \approx \boxed{3 \times 10^{10} \text{ diapers}}$$

(*b*) Express the required landfill volume V in terms of the volume of diapers to be buried:

$$V = NV_{\text{one diaper}}$$

Substitute numerical values and evaluate V:

$$V = \left(3 \times 10^{10} \text{ diapers}\right)\left(0.5\,\text{L/diaper}\right) \approx \boxed{1.5 \times 10^7 \text{ m}^3}$$

(*c*) Express the required volume in terms of the volume of a rectangular parallelepiped:

$$V = Ah$$

Solve and evaluate h:

$$A = \frac{V}{h} = \frac{1.5 \times 10^7 \text{ m}^3}{10\,\text{m}} = 1.5 \times 10^6 \text{ m}^2$$

Use a conversion factor to express this area in square miles:

$$A = 1.5 \times 10^6 \text{ m}^2 \times \frac{1 \text{ mi}^2}{2.590\,\text{km}^2} \approx \boxed{0.6\,\text{mi}^2}$$

16 •••

Picture the Problem The number of bits that can be stored on the disk can be found from the product of the capacity of the disk and the number of bits per byte. In part (*b*) we'll need to estimate (*i*) the number of bits required for the alphabet, (*ii*) the average number of letters per word, (*iii*) an average number of words per line, (*iv*) an average number of lines per page, and (*v*) a book length in pages.

(*a*) Express the number of bits N_{bits} as a function of the number of bits per byte and the capacity of the hard disk N_{bytes}:

$$N_{\text{bits}} = N_{\text{bytes}}\left(8\,\text{bits/byte}\right) = \left(2 \times 10^9 \text{ bytes}\right)\left(8\,\text{bits/byte}\right) = \boxed{1.60 \times 10^{10} \text{ bits}}$$

(*b*) Assume an average of 8 letters/word and 8 bits/character to estimate the number of bytes required per word:

$$8\,\frac{\text{bits}}{\text{character}}\times 8\,\frac{\text{characters}}{\text{word}} = 64\,\frac{\text{bits}}{\text{word}} = 8\,\frac{\text{bytes}}{\text{word}}$$

Assume 10 words/line and 60 lines/page:

$$600\,\frac{\text{words}}{\text{page}}\times 8\,\frac{\text{bytes}}{\text{word}} = 4800\,\frac{\text{bytes}}{\text{page}}$$

Assume a book length of 300 pages and approximate the number bytes required:

$$300\,\text{pages}\times 4800\,\frac{\text{bytes}}{\text{page}} = 1.44\times 10^{6}\ \text{bytes}$$

Divide the number of bytes per disk by our estimated number of bytes required per book to obtain an estimate of the number of books the 2-gigabyte hard disk can hold:

$$N_{\text{books}} = \frac{2\times 10^{9}\ \text{bytes}}{1.44\times 10^{6}\ \text{bytes/book}} \approx \boxed{1400\,\text{books}}$$

***17** ••

Picture the Problem Assume that, on average, four cars go through each toll station per minute. Let R represent the yearly revenue from the tolls. We can estimate the yearly revenue from the number of lanes N, the number of cars per minute n, and the \$6 toll per car C.

$$R = NnC = 14\,\text{lanes}\times 4\,\frac{\text{cars}}{\text{min}}\times 60\,\frac{\text{min}}{\text{h}}\times 24\,\frac{\text{h}}{\text{d}}\times 365.24\,\frac{\text{d}}{\text{y}}\times\frac{\$6}{\text{car}} = \boxed{\$177\text{M}}$$

Units

18 •

Picture the Problem We can use the metric prefixes listed in Table 1-1 and the abbreviations on page EP-1 to express each of these quantities.

(*a*)

$$1{,}000{,}000\,\text{watts} = 10^{6}\ \text{watts} = \boxed{1\,\text{MW}}$$

(*b*)

$$0.002\text{gram} = 2\times 10^{-3}\ \text{g} = \boxed{2\,\text{mg}}$$

(*c*)

$$3\times 10^{-6}\ \text{meter} = \boxed{3\,\mu\text{m}}$$

(*d*)

$$30{,}000\,\text{seconds} = 30\times 10^{3}\ \text{s} = \boxed{30\,\text{ks}}$$

19 •

Picture the Problem We can use the definitions of the metric prefixes listed in Table 1-1 to express each of these quantities without prefixes.

(*a*)

$$40\,\mu\text{W} = 40\times10^{-6}\text{ W} = \boxed{0.000040\,\text{W}}$$

(*b*)

$$4\,\text{ns} = 4\times10^{-9}\text{ s} = \boxed{0.000000004\,\text{s}}$$

(*c*)

$$3\,\text{MW} = 3\times10^{6}\text{ W} = \boxed{3{,}000{,}000\,\text{W}}$$

(*d*)

$$25\,\text{km} = 25\times10^{3}\text{ m} = \boxed{25{,}000\,\text{m}}$$

***20** •

Picture the Problem We can use the definitions of the metric prefixes listed in Table 1-1 to express each of these quantities without abbreviations.

(*a*) $10^{-12}\text{ boo} = \boxed{1\,\text{picoboo}}$

(*b*) $10^{9}\text{ low} = \boxed{1\,\text{gigalow}}$

(*c*) $10^{-6}\text{ phone} = \boxed{1\,\text{microphone}}$

(*d*) $10^{-18}\text{ boy} = \boxed{1\,\text{attoboy}}$

(*e*) $10^{6}\text{ phone} = \boxed{1\,\text{megaphone}}$

(*f*) $10^{-9}\text{ goat} = \boxed{1\,\text{nanogoat}}$

(*g*) $10^{12}\text{ bull} = \boxed{1\,\text{terabull}}$

21 ••

Picture the Problem We can determine the SI units of each term on the right-hand side of the equations from the units of the physical quantity on the left-hand side.

(*a*) Because x is in meters, C_1 and C_2t must be in meters:

$$\boxed{C_1\text{ is in m; }C_2\text{ is in m/s}}$$

(*b*) Because x is in meters, ½C_1t^2 must be in meters:

$$\boxed{C_1\text{ is in m/s}^2}$$

(*c*) Because v^2 is in m^2/s^2, $2C_1x$ must be in m^2/s^2:

$$\boxed{C_1\text{ is in m/s}^2}$$

(*d*) The argument of trigonometric function must be dimensionless; i.e. without units. Therefore, because x

$$\boxed{C_1\text{ is in m; }C_2\text{ is in s}^{-1}}$$

is in meters:

(e) The argument of an exponential function must be dimensionless; i.e. without units. Therefore, because v is in m/s:

$$\boxed{C_1 \text{ is in m/s; } C_2 \text{ is in s}^{-1}}$$

22 ••

Picture the Problem We can determine the US customary units of each term on the right-hand side of the equations from the units of the physical quantity on the left-hand side.

(a) Because x is in feet, C_1 and C_2t must be in feet:

$$\boxed{C_1 \text{ is in ft; } C_2 \text{ is in ft/s}}$$

(b) Because x is in feet, $\frac{1}{2}C_1t^2$ must be in feet:

$$\boxed{C_1 \text{ is in ft/s}^2}$$

(c) Because v^2 is in ft^2/s^2, $2C_1x$ must be in ft^2/s^2:

$$\boxed{C_1 \text{ is in ft/s}^2}$$

(d) The argument of trigonometric function must be dimensionless; i.e. without units. Therefore, because x is in feet:

$$\boxed{C_1 \text{ is in ft; } C_2 \text{ is in s}^{-1}}$$

(e) The argument of an exponential function must be dimensionless; i.e. without units. Therefore, because v is in ft/s:

$$\boxed{C_1 \text{ is in ft/s; } C_2 \text{ is in s}^{-1}}$$

Conversion of Units

23 •

Picture the Problem We can use the formula for the circumference of a circle to find the radius of the earth and the conversion factor 1 mi = 1.61 km to convert distances in meters into distances in miles.

(a) The Pole-Equator distance is one-fourth of the circumference:

$$c = \boxed{4 \times 10^7 \text{ m}}$$

(*b*) Use the formula for the circumference of a circle to obtain:

$$R = \frac{c}{2\pi} = \frac{4\times10^{-7}\text{ m}}{2\pi} = \boxed{6.37\times10^{6}\text{ m}}$$

(*c*) Use the conversion factors 1 km = 1000 m and 1 mi = 1.61 km:

$$c = 4\times10^{7}\text{ m}\times\frac{1\text{ km}}{10^{3}\text{ m}}\times\frac{1\text{ mi}}{1.61\text{ km}} = \boxed{2.48\times10^{4}\text{ mi}}$$

and

$$R = 6.37\times10^{6}\text{ m}\times\frac{1\text{ km}}{10^{3}\text{ m}}\times\frac{1\text{ mi}}{1.61\text{ km}} = \boxed{3.96\times10^{3}\text{ mi}}$$

24 •

Picture the Problem We can use the conversion factor 1 mi = 1.61 km to convert speeds in km/h into mi/h.

Find the speed of the plane in km/s:

$$v = 2(340\text{ m/s}) = 680\text{ m/s}$$
$$= \left(680\frac{\text{m}}{\text{s}}\right)\left(\frac{1\text{ km}}{10^{3}\text{ m}}\right)\left(3600\frac{\text{s}}{\text{h}}\right) = \boxed{2450\text{ km/h}}$$

Convert v into mi/h:

$$v = \left(2450\frac{\text{km}}{\text{h}}\right)\left(\frac{1\text{ mi}}{1.61\text{ km}}\right) = \boxed{1520\text{ mi/h}}$$

***25** •

Picture the Problem We'll first express his height in inches and then use the conversion factor 1 in = 2.54 cm.

Express the player's height into inches:

$$h = 6\text{ ft}\times\frac{12\text{ in}}{\text{ft}} + 10.5\text{ in} = 82.5\text{ in}$$

Convert h into cm:

$$h = 82.5\text{ in}\times\frac{2.54\text{ cm}}{\text{in}} = \boxed{210\text{ cm}}$$

26 •

Picture the Problem We can use the conversion factors 1 mi = 1.61 km, 1 in = 2.54 cm, and 1 m = 1.094 yd to complete these conversions.

(*a*) $$100\,\frac{\text{km}}{\text{h}}=100\,\frac{\text{km}}{\text{h}}\times\frac{1\,\text{mi}}{1.61\,\text{km}}=\boxed{62.1\,\frac{\text{mi}}{\text{h}}}$$

(*b*) $$60\,\text{cm}=60\,\text{cm}\times\frac{1\,\text{in}}{2.54\,\text{cm}}=\boxed{23.6\,\text{in}}$$

(*c*) $$100\,\text{yd}=100\,\text{yd}\times\frac{1\,\text{m}}{1.094\,\text{yd}}=\boxed{91.4\,\text{m}}$$

27 •

Picture the Problem We can use the conversion factor 1.609 km = 5280 ft to convert the length of the main span of the Golden Gate Bridge into kilometers.

Convert 4200 ft into km:

$$4200\,\text{ft}=4200\,\text{ft}\times\frac{1.609\,\text{km}}{5280\,\text{ft}}=\boxed{1.28\,\text{km}}$$

***28** •

Picture the Problem Let *v* be the speed of an object in mi/h. We can use the conversion factor 1 mi = 1.61 km to convert this speed to km/h.

Multiply *v* mi/h by 1.61 km/mi to convert *v* to km/h:

$$v\,\frac{\text{mi}}{\text{h}}=v\,\frac{\text{mi}}{\text{h}}\times\frac{1.61\,\text{km}}{\text{mi}}=\boxed{1.61v\,\text{km/h}}$$

29 •

Picture the Problem Use the conversion factors 1 h = 3600 s, 1.609 km = 1 mi, and 1 mi = 5280 ft to make these conversions.

(*a*) $$1.296\times10^5\,\frac{\text{km}}{\text{h}^2}=\left(1.296\times10^5\,\frac{\text{km}}{\text{h}^2}\right)\left(\frac{1\,\text{h}}{3600\,\text{s}}\right)=\boxed{36.0\,\frac{\text{km}}{\text{h}\cdot\text{s}}}$$

(*b*) $$1.296\times10^5\,\frac{\text{km}}{\text{h}^2}=\left(1.296\times10^5\,\frac{\text{km}}{\text{h}^2}\right)\left(\frac{1\,\text{h}}{3600\,\text{s}}\right)^2\left(\frac{10^3\,\text{m}}{\text{km}}\right)=\boxed{10.0\,\frac{\text{m}}{\text{s}^2}}$$

(*c*) $$60\,\frac{\text{mi}}{\text{h}}=\left(60\,\frac{\text{mi}}{\text{h}}\right)\left(\frac{5280\,\text{ft}}{1\,\text{mi}}\right)\left(\frac{1\,\text{h}}{3600\,\text{s}}\right)=\boxed{88.0\,\frac{\text{ft}}{\text{s}}}$$

(*d*) $$60\,\frac{\text{mi}}{\text{h}}=\left(60\,\frac{\text{mi}}{\text{h}}\right)\left(\frac{1.609\,\text{km}}{1\,\text{mi}}\right)\left(\frac{10^3\,\text{m}}{\text{km}}\right)\left(\frac{1\,\text{h}}{3600\,\text{s}}\right)=\boxed{26.8\,\frac{\text{m}}{\text{s}}}$$

30 •

Picture the Problem We can use the conversion factor 1 L = 1.057 qt to convert gallons into liters and then use this gallons-to-liters conversion factor to convert barrels into cubic meters.

$$(a)\ 1\,\text{gal} = (1\,\text{gal})\left(\frac{4\,\text{qt}}{\text{gal}}\right)\left(\frac{1\,\text{L}}{1.057\,\text{qt}}\right) = \boxed{3.784\,\text{L}}$$

$$(b)\ 1\,\text{barrel} = (1\,\text{barrel})\left(\frac{42\,\text{gal}}{\text{barrel}}\right)\left(\frac{3.784\,\text{L}}{\text{gal}}\right)\left(\frac{10^{-3}\,\text{m}^3}{\text{L}}\right) = \boxed{0.1589\,\text{m}^3}$$

31 •

Picture the Problem We can use the conversion factor given in the problem statement and the fact that 1 mi = 1.609 km to express the number of square meters in one acre.

Multiply by 1 twice, properly chosen, to convert one acre into square miles, and then into square meters:

$$1\,\text{acre} = (1\,\text{acre})\left(\frac{1\,\text{mi}^2}{640\,\text{acres}}\right)\left(\frac{1609\,\text{m}}{\text{mi}}\right)^2$$

$$= \boxed{4050\,\text{m}^2}$$

32 ••

Picture the Problem The volume of a right circular cylinder is the area of its base multiplied by its height. Let d represent the diameter and h the height of the right circular cylinder; use conversion factors to express the volume V in the given units.

(*a*) Express the volume of the cylinder:

$$V = \tfrac{1}{4}\pi d^2 h$$

Substitute numerical values and evaluate V:

$$V = \tfrac{1}{4}\pi(6.8\,\text{in})^2(2\,\text{ft})$$

$$= \tfrac{1}{4}\pi(6.8\,\text{in})^2(2\,\text{ft})\left(\frac{1\,\text{ft}}{12\,\text{in}}\right)^2$$

$$= \boxed{0.504\,\text{ft}^3}$$

(*b*) Use the fact that 1 m = 3.281 ft to convert the volume in cubic feet into cubic meters:

$$V = (0.504\,\text{ft}^3)\left(\frac{1\,\text{m}}{3.281\,\text{ft}}\right)^3$$

$$= \boxed{0.0143\,\text{m}^3}$$

(*c*) Because 1 L = 10^{-3} m^3:

$$V = (0.0143\,\text{m}^3)\left(\frac{1\,\text{L}}{10^{-3}\,\text{m}^3}\right) = \boxed{14.3\,\text{L}}$$

***33** ••

Picture the Problem We can treat the SI units as though they are algebraic quantities to simplify each of these combinations of physical quantities and constants.

(*a*) Express and simplify the units of v^2/x:

$$\frac{(\text{m/s})^2}{\text{m}} = \frac{\text{m}^2}{\text{m}\cdot\text{s}^2} = \boxed{\frac{\text{m}}{\text{s}^2}}$$

(*b*) Express and simplify the units of $\sqrt{x/a}$:

$$\sqrt{\frac{\text{m}}{\text{m/s}^2}} = \sqrt{\text{s}^2} = \boxed{\text{s}}$$

(*c*) Noting that the constant factor $\frac{1}{2}$ has no units, express and simplify the units of $\frac{1}{2}at^2$:

$$\left(\frac{\text{m}}{\text{s}^2}\right)(\text{s})^2 = \left(\frac{\text{m}}{\text{s}^2}\right)(\text{s}^2) = \boxed{\text{m}}$$

Dimensions of Physical Quantities

34 •

Picture the Problem We can use the facts that each term in an equation must have the same dimensions and that the arguments of a trigonometric or exponential function must be dimensionless to determine the dimensions of the constants.

(*a*)

$$x = C_1 + C_2 \; t$$

$$L \qquad \boxed{L} \qquad \boxed{\frac{L}{T}} \; T$$

(*b*)

$$x = \tfrac{1}{2} \; C_1 \; t^2$$

$$L \qquad \boxed{\frac{L}{T^2}} \; T^2$$

(*c*)

$$v^2 = 2 \; C_1 \; x$$

$$\frac{L^2}{T^2} \qquad \boxed{\frac{L}{T^2}} \; L$$

(*d*)

$$x = C_1 \cos C_2 \; t$$

$$L \qquad \boxed{L} \qquad \boxed{\frac{1}{T}} \; T$$

(*e*)

$$v = C_1 \exp(-C_2 \; t)$$

$$\frac{L}{T} \qquad \boxed{\frac{L}{T}} \qquad \boxed{\frac{1}{T}} \; T$$

35 ••

Picture the Problem Because the exponent of the exponential function must be dimension the dimension of λ must be $\boxed{T^{-1}.}$

***36 ••**

Picture the Problem We can solve Newton's law of gravitation for *G* and substitute the dimensions of the variables. Treating them as algebraic quantities will allow us to express the dimensions in their simplest form. Finally, we can substitute the SI units for the dimensions to find the units of *G*.

Solve Newton's law of gravitation for *G* to obtain:

$$G=\frac{Fr^2}{m_1m_2}$$

Substitute the dimensions of the variables:

$$G=\frac{\frac{ML}{T^2}\times L^2}{M^2}=\boxed{\frac{L^3}{MT^2}}$$

Use the SI units for *L, M,* and *T*:

$$\text{Units of } G \text{ are } \boxed{\frac{\text{m}^3}{\text{kg}\cdot\text{s}^2}}$$

37 ••

Picture the Problem Let *m* represent the mass of the object, *v* its speed, and *r* the radius of the circle in which it moves. We can express the force as the product of *m*, *v*, and *r* (each raised to a power) and then use the dimensions of force *F,* mass *m,* speed *v,* and radius *r* to obtain three equations in the assumed powers. Solving these equations simultaneously will give us the dependence of *F* on *m, v,* and *r.*

Express the force in terms of powers of the variables:

$$F=m^av^br^c$$

Substitute the dimensions of the physical quantities:

$$MLT^{-2}=M^a\left(\frac{L}{T}\right)^bL^c$$

Simplify to obtain:

$$MLT^{-2}=M^aL^{b+c}T^{-b}$$

Equate the exponents to obtain:

$a = 1$,
$b + c = 1$, and
$-b = -2$

Solve this system of equations to obtain:

$a = 1$, $b = 2$, and $c = -1$

Substitute in equation (1):

$$F=mv^2r^{-1}=\boxed{m\frac{v^2}{r}}$$

38 ••

Picture the Problem We note from Table 1-2 that the dimensions of power are ML^2/T^3. The dimensions of mass, acceleration, and speed are M, L/T^2, and L/T respectively.

Express the dimensions of *mav*:

$$[mav] = M \times \frac{L}{T^2} \times \frac{L}{T} = \frac{ML^2}{T^3}$$

From Table 1-2:

$$[P] = \frac{ML^2}{T^3}$$

Comparing these results, we see that the product of mass, acceleration, and speed has the dimensions of power.

39 ••

Picture the Problem The dimensions of mass and velocity are M and L/T, respectively. We note from Table 1-2 that the dimensions of force are ML/T^2.

Express the dimensions of momentum:

$$[mv] = M \times \frac{L}{T} = \frac{ML}{T}$$

From Table 1-2:

$$[F] = \frac{ML}{T^2}$$

Express the dimensions of force multiplied by time:

$$[Ft] = \frac{ML}{T^2} \times T = \frac{ML}{T}$$

Comparing these results, we see that momentum has the dimensions of force multiplied by time.

40 ••

Picture the Problem Let *X* represent the physical quantity of interest. Then we can express the dimensional relationship between *F, X,* and *P* and solve this relationship for the dimensions of *X*.

Express the relationship of *X* to force and power dimensionally:

$$[F][X] = [P]$$

Solve for $[X]$:

$$[X] = \frac{[P]}{[F]}$$

Substitute the dimensions of force and power and simplify to obtain:

$$[X]=\frac{\frac{ML^2}{T^3}}{\frac{ML}{T^2}}=\frac{L}{T}$$

Because the dimensions of velocity are L/T, we can conclude that:

$$\boxed{[P]=[F][v]}$$

Remarks: While it is true that $P = Fv$, dimensional analysis does not reveal the presence of dimensionless constants. For example, if $P = \pi Fv$, the analysis shown above would fail to establish the factor of π.

***41** ••

Picture the Problem We can find the dimensions of C by solving the drag force equation for C and substituting the dimensions of force, area, and velocity.

Solve the drag force equation for the constant C:

$$C=\frac{F_{\text{air}}}{Av^2}$$

Express this equation dimensionally:

$$[C]=\frac{[F_{\text{air}}]}{[A][v]^2}$$

Substitute the dimensions of force, area, and velocity and simplify to obtain:

$$[C]=\frac{\frac{ML}{T^2}}{L^2\left(\frac{L}{T}\right)^2}=\boxed{\frac{M}{L^3}}$$

42 ••

Picture the Problem We can express the period of a planet as the product of these factors (each raised to a power) and then perform dimensional analysis to determine the values of the exponents.

Express the period T of a planet as the product of r^a, G^b, and M_S^c:

$$T = Cr^aG^bM_S^c \qquad (1)$$

where C is a dimensionless constant.

Solve the law of gravitation for the constant G:

$$G=\frac{Fr^2}{m_1m_2}$$

Express this equation dimensionally:

$$[G]=\frac{[F][r]^2}{[m_1][m_2]}$$

Substitute the dimensions of F, r, and m:

$$[G]=\frac{\frac{ML}{T^2}\times(L)^2}{M\times M}=\frac{L^3}{MT^2}$$

Noting that the dimension of time is represented by the same letter as is the period of a planet, substitute the dimensions in equation (1) to obtain:

$$T=(L)^a\left(\frac{L^3}{MT^2}\right)^b(M)^c$$

Introduce the product of M^0 and L^0 in the left hand side of the equation and simplify to obtain:

$$M^0L^0T^1=M^{c-b}L^{a+3b}T^{-2b}$$

Equate the exponents on the two sides of the equation to obtain:

$0 = c - b$,
$0 = a + 3b$, and
$1 = -2b$

Solve these equations simultaneously to obtain:

$$a=\tfrac{3}{2},\ b=-\tfrac{1}{2},\ \text{and}\ c=-\tfrac{1}{2}$$

Substitute in equation (1):

$$T=Cr^{3/2}G^{-1/2}M_S^{-1/2}=\boxed{\frac{C}{\sqrt{GM_S}}r^{3/2}}$$

Scientific Notation and Significant Figures

***43 •**

Picture the Problem We can use the rules governing scientific notation to express each of these numbers as a decimal number.

(*a*) $3\times10^4=\boxed{30{,}000}$

(*b*) $6.2\times10^{-3}=\boxed{0.0062}$

(*c*) $4\times10^{-6}=\boxed{0.000004}$

(*d*) $2.17\times10^5=\boxed{217{,}000}$

44 •

Picture the Problem We can use the rules governing scientific notation to express each of these measurements in scientific notation.

(*a*) $3.1\,\text{GW}=\boxed{3.1\times10^9\ \text{W}}$

(*c*) $2.3\,\text{fs}=\boxed{2.3\times10^{-15}\ \text{s}}$

(*b*) $10\,\text{pm} = 10 \times 10^{-12}\ \text{m} = \boxed{10^{-11}\ \text{m}}$ (*d*) $4\,\mu\text{s} = \boxed{4 \times 10^{-6}\ \text{s}}$

45 •

Picture the Problem Apply the general rules concerning the multiplication, division, addition, and subtraction of measurements to evaluate each of the given expressions.

(*a*) The number of significant figures in each factor is three; therefore the result has three significant figures:

$$(1.14)(9.99 \times 10^4) = \boxed{1.14 \times 10^5}$$

(*b*) Express both terms with the same power of 10. Because the first measurement has only two digits after the decimal point, the result can have only two digits after the decimal point:

$$(2.78 \times 10^{-8}) - (5.31 \times 10^{-9}) = (2.78 - 0.531) \times 10^{-8} = \boxed{2.25 \times 10^{-8}}$$

(*c*) We'll assume that 12 is exact. Hence, the answer will have three significant figures:

$$\frac{12\pi}{4.56 \times 10^{-3}} = \boxed{8.27 \times 10^3}$$

(*d*) Proceed as in (*b*):

$$27.6 + (5.99 \times 10^2) = 27.6 + 599 = 627 = \boxed{6.27 \times 10^2}$$

46 •

Picture the Problem Apply the general rules concerning the multiplication, division, addition, and subtraction of measurements to evaluate each of the given expressions.

(*a*) Note that both factors have four significant figures.

$$(200.9)(569.3) = \boxed{1.144 \times 10^5}$$

(*b*) Express the first factor in scientific notation and note that both factors have three significant figures.

$$(0.000000513)(62.3 \times 10^7) = (5.13 \times 10^{-7})(62.3 \times 10^7) = \boxed{3.20 \times 10^2}$$

(*c*) Express both terms in scientific notation and note that the second has only three significant figures. Hence the result will have only three significant figures.

$$28401+\left(5.78\times10^{4}\right)=\left(2.841\times10^{4}\right)+\left(5.78\times10^{4}\right)=\left(2.841+5.78\right)\times10^{4}=\boxed{8.62\times10^{4}}$$

(*d*) Because the divisor has three significant figures, the result will have three significant figures.

$$\frac{63.25}{4.17\times10^{-3}}=\boxed{1.52\times10^{4}}$$

***47 •**

Picture the Problem Let N represent the required number of membranes and express N in terms of the thickness of each cell membrane.

Express N in terms of the thickness of a single membrane:

$$N=\frac{1\,\text{in}}{7\,\text{nm}}$$

Convert the units into SI units and simplify to obtain:

$$N=\frac{1\,\text{in}}{7\,\text{nm}}\times\frac{2.54\,\text{cm}}{\text{in}}\times\frac{1\,\text{m}}{100\,\text{cm}}\times\frac{1\,\text{nm}}{10^{-9}\,\text{m}}=\boxed{4\times10^{6}}$$

48 •

Picture the Problem Apply the general rules concerning the multiplication, division, addition, and subtraction of measurements to evaluate each of the given expressions.

(*a*) Both factors and the result have three significant figures:

$$\left(2.00\times10^{4}\right)\left(6.10\times10^{-2}\right)=\boxed{1.22\times10^{3}}$$

(*b*) Because the second factor has three significant figures, the result will have three significant figures:

$$\left(3.141592\right)\left(4.00\times10^{5}\right)=\boxed{1.26\times10^{6}}$$

(*c*) Both factors and the result have three significant figures:

$$\frac{2.32\times10^{3}}{1.16\times10^{8}}=\boxed{2.00\times10^{-5}}$$

(*d*) Write both terms using the same power of 10. Note that the result will have only three significant figures:

$$\left(5.14\times10^{3}\right)+\left(2.78\times10^{2}\right)=\left(5.14\times10^{3}\right)+\left(0.278\times10^{3}\right)=\left(5.14+0.278\right)\times10^{3}=\boxed{5.42\times10^{3}}$$

(*e*) Follow the same procedure used in (*d*):

$$\left(1.99\times10^{2}\right)+\left(9.99\times10^{-5}\right)$$
$$=\left(1.99\times10^{2}\right)+\left(0.000000999\times10^{2}\right)$$
$$=\boxed{1.99\times10^{2}}$$

***49** •

Picture the Problem Apply the general rules concerning the multiplication, division, addition, and subtraction of measurements to evaluate each of the given expressions.

(*a*) The second factor and the result have three significant figures:

$$3.141592654\times(23.2)^{2}=\boxed{1.69\times10^{3}}$$

(*b*) We'll assume that 2 is exact. Therefore, the result will have two significant figures:

$$2\times3.141592654\times0.76=\boxed{4.8}$$

(*c*) We'll assume that 4/3 is exact. Therefore the result will have two significant figures:

$$\frac{4}{3}\pi\times(1.1)^{3}=\boxed{5.6}$$

(*d*) Because 2.0 has two significant figures, the result has two significant figures:

$$\frac{(2.0)^{5}}{3.141592654}=\boxed{10}$$

General Problems

50 •

Picture the Problem We can use the conversion factor 1 mi = 1.61 km to convert 100 km/h into mi/h.

Multiply 100 km/h by 1 mi/1.61 km to obtain:

$$100\frac{\text{km}}{\text{h}}=100\frac{\text{km}}{\text{h}}\times\frac{1\text{mi}}{1.61\text{km}}$$
$$=\boxed{62.1\text{mi/h}}$$

***51** •

Picture the Problem We can use a series of conversion factors to convert 1 billion seconds into years.

Multiply 1 billion seconds by the appropriate conversion factors to convert into years:

$$10^9\ \text{s} = 10^9\ \text{s} \times \frac{1\,\text{h}}{3600\,\text{s}} \times \frac{1\,\text{day}}{24\,\text{h}} \times \frac{1\,\text{y}}{365.24\,\text{days}} = \boxed{31.7\,\text{y}}$$

52 •

Picture the Problem In both the examples cited we can equate expressions for the physical quantities, expressed in different units, and then divide both sides of the equation by one of the expressions to obtain the desired conversion factor.

(*a*) Divide both sides of the equation expressing the speed of light in the two systems of measurement by 186,000 mi/s to obtain:

$$1 = \frac{3 \times 10^8\ \text{m/s}}{1.86 \times 10^5\ \text{mi/h}} = 1.61 \times 10^3\ \text{m/mi}$$

$$= \left(1.61 \times 10^3\ \frac{\text{m}}{\text{mi}}\right)\left(\frac{1\,\text{km}}{10^3\ \text{m}}\right)$$

$$= \boxed{1.61\,\text{km/mi}}$$

(*b*) Find the volume of 1.00 kg of water:

Volume of 1.00 kg = 10^3 g is 10^3 cm^3

Express 10^3 cm^3 in ft^3:

$$(10\,\text{cm})^3\left(\frac{1\,\text{in}}{2.54\,\text{cm}}\right)^3\left(\frac{1\,\text{ft}}{12\,\text{in}}\right)^3$$

$$= 0.0353\,\text{ft}^3$$

Relate the weight of 1 ft^3 of water to the volume occupied by 1 kg of water:

$$\frac{1.00\,\text{kg}}{0.0353\,\text{ft}^3} = 62.4\frac{\text{lb}}{\text{ft}^3}$$

Divide both sides of the equation by the left-hand side to obtain:

$$1 = \frac{62.4\dfrac{\text{lb}}{\text{ft}^3}}{\dfrac{1.00\,\text{kg}}{0.0353\,\text{ft}^3}} = \boxed{2.20\,\text{lb/kg}}$$

53 ••

Picture the Problem We can use the given information to equate the ratios of the number of uranium atoms in 8 g of pure uranium and of 1 atom to its mass.

Express the proportion relating the number of uranium atoms N_U in 8 g of pure uranium to the mass of 1 atom:

$$\frac{N_U}{8\,\text{g}} = \frac{1\,\text{atom}}{4.0 \times 10^{-26}\ \text{kg}}$$

Solve for and evaluate N_U:

$$N_U = (8\,\text{g})\left(\frac{1\,\text{atom}}{4.0\times10^{-26}\,\text{kg}}\right) = \boxed{2.0\times10^{23}}$$

54 ••

Picture the Problem We can relate the weight of the water to its weight per unit volume and the volume it occupies.

Express the weight w of water falling on the acre in terms of the weight of one cubic foot of water, the depth d of the water, and the area A over which the rain falls:

$$w = \left(62.4\,\frac{\text{lb}}{\text{ft}^3}\right)Ad$$

Find the area A in ft^2:

$$A = (1\,\text{acre})\left(\frac{1\,\text{mi}^2}{640\,\text{acre}}\right)\left(\frac{5280\,\text{ft}}{\text{mi}}\right)^2 = 4.356\times10^4\,\text{ft}^2$$

Substitute numerical values and evaluate w:

$$w = \left(62.4\,\frac{\text{lb}}{\text{ft}^3}\right)\left(4.356\times10^4\,\text{ft}^2\right)(1.4\,\text{in})\left(\frac{1\,\text{ft}}{12\,\text{in}}\right) = \boxed{3.17\times10^5\,\text{lb}}$$

55 ••

Picture the Problem We can use the definition of density and the formula for the volume of a sphere to find the density of iron. Once we know the density of iron, we can use these same relationships to find what the radius of the earth would be if it had the same mass per unit volume as iron.

(*a*) Using its definition, express the density of iron:

$$\rho = \frac{m}{V}$$

Assuming it to be spherical, express the volume of an iron nucleus as a function of its radius:

$$V = \tfrac{4}{3}\pi r^3$$

Substitute to obtain:

$$\rho = \frac{3m}{4\pi r^3} \qquad (1)$$

Substitute numerical values and evaluate ρ:

$$\rho = \frac{3\left(9.3\times10^{-26}\ \text{kg}\right)}{4\pi\left(5.4\times10^{-15}\ \text{m}\right)^3} = \boxed{1.41\times10^{17}\ \text{kg/m}^3}$$

(*b*) Because equation (1) relates the density of any spherical object to its mass and radius, we can solve for *r* to obtain:

$$r = \sqrt[3]{\frac{3m}{4\pi\rho}}$$

Substitute numerical values and evaluate *r*:

$$r = \sqrt[3]{\frac{3\left(5.98\times10^{24}\ \text{kg}\right)}{4\pi\left(1.41\times10^{17}\ \text{kg/m}^3\right)}} = \boxed{216\,\text{m}}$$

56 ••

Picture the Problem Apply the general rules concerning the multiplication, division, addition, and subtraction of measurements to evaluate each of the given expressions.

(*a*) Because all of the factors have two significant figures, the result will have two significant figures:

$$\frac{\left(5.6\times10^{-5}\right)\left(0.0000075\right)}{2.4\times10^{-12}} = \frac{\left(5.6\times10^{-5}\right)\left(7.5\times10^{-6}\right)}{2.4\times10^{-12}} = \boxed{1.8\times10^{2}}$$

(*b*) Because the factor with the fewest significant figures in the first term has two significant figures, the result will have two significant figures. Because its last significant figure is in the tenth's position, the difference between the first and second term will have its last significant figure in the tenth's position:

$$\left(14.2\right)\left(6.4\times10^{7}\right)\left(8.2\times10^{-9}\right) - 4.06 = 7.8 - 4.06 = \boxed{3.4}$$

(*c*) Because all of the factors have two significant figures, the result will have two significant figures:

$$\frac{\left(6.1\times10^{-6}\right)^2\left(3.6\times10^{4}\right)^3}{\left(3.6\times10^{-11}\right)^{1/2}} = \boxed{2.9\times10^{8}}$$

(*d*) Because the factor with the fewest significant figures has two significant figures, the result will have two significant figures.

$$\frac{(0.000064)^{1/3}}{(12.8\times10^{-3})(490\times10^{-1})^{1/2}} = \frac{(6.4\times10^{-5})^{1/3}}{(12.8\times10^{-3})(490\times10^{-1})^{1/2}} = \boxed{0.45}$$

***57 ••**

Picture the Problem We can use the relationship between an angle θ, measured in radians, subtended at the center of a circle, the radius R of the circle, and the length L of the arc to answer these questions concerning the astronomical units of measure.

(*a*) Relate the angle θ subtended by an arc of length S to the distance R:

$$\theta = \frac{S}{R} \qquad (1)$$

Solve for and evaluate S:

$$S = R\theta = (1\,\text{parsec})(1\,\text{s})\left(\frac{1\,\text{min}}{60\,\text{s}}\right)\times\left(\frac{1°}{60\,\text{min}}\right)\left(\frac{2\pi\,\text{rad}}{360°}\right) = \boxed{4.85\times10^{-6}\,\text{parsec}}$$

(*b*) Solve equation (1) for and evaluate R:

$$R = \frac{S}{\theta} = \frac{1.496\times10^{11}\,\text{m}}{(1\,\text{s})\left(\frac{1\,\text{min}}{60\,\text{s}}\right)\left(\frac{1°}{60\,\text{min}}\right)\left(\frac{2\pi\,\text{rad}}{360°}\right)} = \boxed{3.09\times10^{16}\,\text{m}}$$

(*c*) Relate the distance D light travels in a given interval of time Δt to its speed c and evaluate D for Δt = 1 y:

$$D = c\Delta t = \left(3\times10^{8}\,\frac{\text{m}}{\text{s}}\right)(1\,\text{y})\left(3.156\times10^{7}\,\frac{\text{s}}{\text{y}}\right) = \boxed{9.47\times10^{15}\,\text{m}}$$

(*d*) Use the definition of 1 AU and the result from part (*c*) to obtain:

$$1c\cdot\text{y} = \left(9.47\times10^{15}\text{ m}\right)\left(\frac{1\text{AU}}{1.496\times10^{11}\text{ m}}\right)$$
$$= \boxed{6.33\times10^{4}\text{ AU}}$$

(*e*) Combine the results of parts (*b*) and (*c*) to obtain:

$$1\text{parsec} = \left(3.08\times10^{16}\text{ m}\right)\times\left(\frac{1c\cdot\text{y}}{9.47\times10^{15}\text{ m}}\right)$$
$$= \boxed{3.25c\cdot\text{y}}$$

58 ••

Picture the Problem Let N_e and N_p represent the number of electrons and the number of protons, respectively and ρ the critical average density of the universe. We can relate these quantities to the masses of the electron and proton using the definition of density.

(*a*) Using its definition, relate the required density ρ to the electron density N_e/V:

$$\rho = \frac{m}{V} = \frac{N_e m_e}{V}$$

Solve for N_e/V:

$$\frac{N_e}{V} = \frac{\rho}{m_e} \qquad (1)$$

Substitute numerical values and evaluate N_e/V:

$$\frac{N_e}{V} = \frac{6\times10^{-27}\text{ kg/m}^3}{9.11\times10^{-31}\text{ kg/electron}}$$
$$= \boxed{6.59\times10^{3}\text{ electrons/m}^3}$$

(*b*) Express and evaluate the ratio of the masses of an electron and a proton:

$$\frac{m_e}{m_p} = \frac{9.11\times10^{-31}\text{ kg}}{1.67\times10^{-27}\text{ kg}} = 5.46\times10^{-4}$$

Rewrite equation (1) in terms of protons:

$$\frac{N_p}{V} = \frac{\rho}{m_p} \qquad (2)$$

Divide equation (2) by equation (1) to obtain:

$$\frac{\frac{N_p}{V}}{\frac{N_e}{V}} = \frac{m_e}{m_p} \text{ or } \frac{N_p}{V} = \frac{m_e}{m_p}\left(\frac{N_e}{V}\right)$$

Substitute numerical values and use the result from part (*a*) to evaluate N_p/V:

$$\frac{N_p}{V} = \left(5.46\times10^{-4}\right)\times\left(6.59\times10^{3}\ \text{protons/m}^3\right) = \boxed{3.59\ \text{protons/m}^3}$$

***59** ••

Picture the Problem We can use the definition of density to relate the mass of the water in the cylinder to its volume and the formula for the volume of a cylinder to express the volume of water used in the detector's cylinder. To convert our answer in kg to lb, we can use the fact that 1 kg weighs about 2.205 lb.

Relate the mass of water contained in the cylinder to its density and volume:

$$m = \rho V$$

Express the volume of a cylinder in terms of its diameter d and height h:

$$V = A_{\text{base}}h = \frac{\pi}{4}d^2h$$

Substitute to obtain:

$$m = \rho\frac{\pi}{4}d^2h$$

Substitute numerical values and evaluate m:

$$m = \left(10^3\ \text{kg/m}^3\right)\left(\frac{\pi}{4}\right)(39.3\ \text{m})^2(41.4\ \text{m}) = 5.02\times10^7\ \text{kg}$$

Convert 5.02×10^7 kg to tons:

$$m = 5.02\times10^7\ \text{kg}\times\frac{2.205\ \text{lb}}{\text{kg}}\times\frac{1\ \text{ton}}{2000\ \text{lb}} = 55.4\times10^3\ \text{ton}$$

$$\boxed{\text{The 50,000-ton claim is conservative. The actual weight is closer to 55,000 tons.}}$$

60 •••

Picture the Problem We'll solve this problem two ways. First, we'll substitute two of the ordered pairs in the given equation to obtain two equations in C and n that we can solve simultaneously. Then we'll use a spreadsheet program to create a graph of log T as a function of log m and use its curve-fitting capability to find n and C. Finally, we can identify the data points that deviate the most from a straight-line plot by examination of the graph.

1st Solution for (*a*)

(*a*) To estimate *C* and *n*, we can apply the relation $T = Cm^n$ to two arbitrarily selected data points. We'll use the 1st and 6th ordered pairs. This will produce simultaneous equations that can be solved for *C* and *n*.

$$T_1 = Cm_1^n$$
and
$$T_6 = Cm_6^n$$

Divide the second equation by the first to obtain:

$$\frac{T_6}{T_1} = \frac{Cm_6^n}{Cm_1^2} = \left(\frac{m_6}{m_1}\right)^n$$

Substitute numerical values and solve for *n* to obtain:

$$\frac{1.75\,\text{s}}{0.56\,\text{s}} = \left(\frac{1\,\text{kg}}{0.1\,\text{kg}}\right)^n$$
or
$$3.125 = 10^n \Rightarrow n = \boxed{0.4948}$$
and so a ″judicial″ guess is that $n = 0.5$.

Substituting this value into the second equation gives:

$$T_5 = Cm_5^{0.5}$$
so
$$1.75\,\text{s} = \text{C}(1\,\text{kg})^{0.5}$$

Solving for *C* gives:

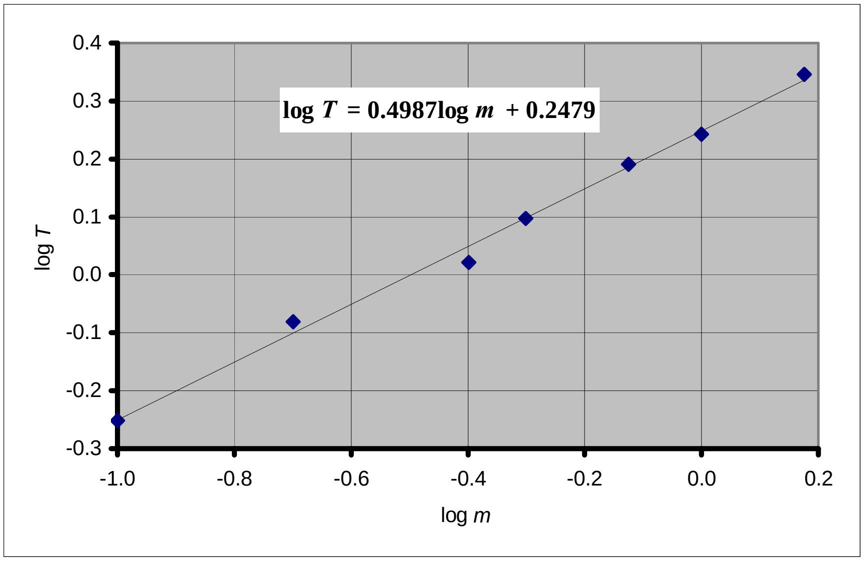
$$C = \boxed{1.75\,\text{s/kg}^{0.5}}$$

2nd Solution for (*a*)

Take the logarithm (we'll arbitrarily use base 10) of both sides of $T = Cm^n$ and simplify to obtain:

$$\log(T) = \log(Cm^n) = \log C + \log m^n$$
$$= n \log m + \log C$$
which, we note, is of the form $y = mx + b$. Hence a graph of log T vs. log m should be linear with a slope of *n* and a log *T*-intercept log *C*.

The graph of log *T* vs. log *m* shown below was created using a spreadsheet program. The equation shown on the graph was obtained using Excel's ″Add Trendline″ function. (Excel's ″Add Trendline″ function uses regression analysis to generate the trendline.)



Comparing the equation on the graph generated by the Add Trendline function to $\log(T) = n\log m + \log C$, we observe:

$$n = \boxed{0.499}$$

and

$$C = 10^{0.2479} = \boxed{1.77\ \text{s/kg}^{1/2}}$$

or

$$T = \boxed{\left(1.77\ \text{s/kg}^{1/2}\right)m^{0.499}}$$

(*b*) From the graph we see that the data points that deviate the most from a straight-line plot are:

$$\boxed{m = 0.02\ \text{kg},\ T = 0.471\ \text{s, and } m = 1.50\ \text{kg},\ T = 2.22\ \text{s}}$$

(*b*) From the graph we see that the points generated using the data pairs (0.02 kg, 0.471 s) and (0.4 kg, 1.05 s) deviate the most from the line representing the best fit to the points plotted on the graph.

Remarks: Still another way to find *n* and *C* is to use your graphing calculator to perform regression analysis on the given set of data for log *T* versus log *m*. The slope yields *n* and the *y*-intercept yields log *C*.

61 •••

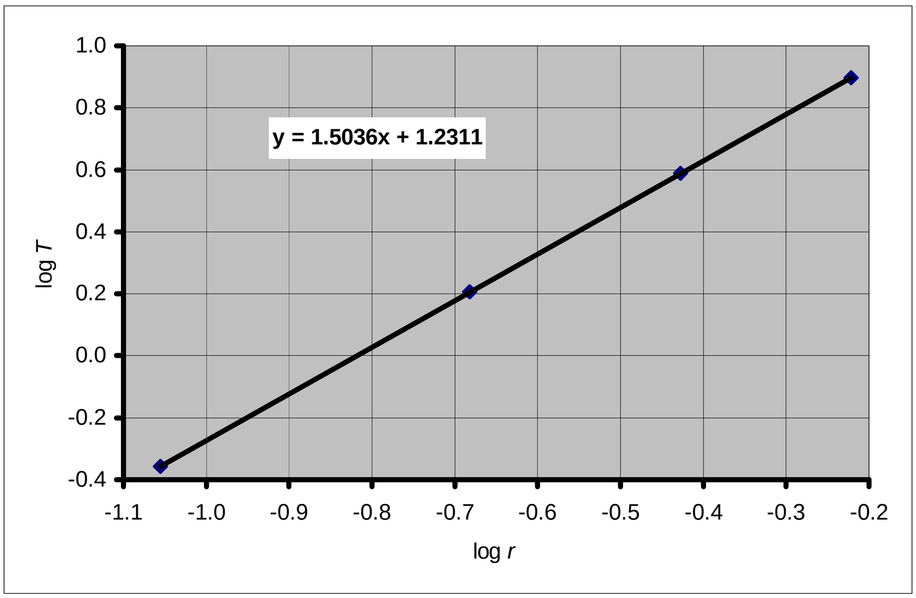
Picture the Problem We can plot log T versus log r and find the slope of the best-fit line to determine the exponent n. We can then use any of the ordered pairs to evaluate C. Once we know n and C, we can solve $T = Cr^n$ for r as a function of T.

(*a*) Take the logarithm (we'll arbitrarily use base 10) of both sides of $T = Cr^n$ and simplify to obtain:

$$\log(T) = \log(Cr^n) = \log C + \log r^n$$
$$= n\log r + \log C$$

Note that this equation is of the form $y = mx + b$. Hence a graph of log T vs. log r should be linear with a slope of n and a log T -intercept log C.

The graph of log T versus log r shown below was created using a spreadsheet program. The equation shown on the graph was obtained using Excel's ″Add Trendline″ function. (Excel's ″Add Trendline″ function uses regression analysis to generate the trendline.)



From the regression analysis we observe that:

$$n = \boxed{1.50}$$

and

$$C = 10^{1.2311} = \boxed{17.0\,\text{y}/(\text{Gm})^{3/2}}$$

or $$T = \boxed{\left(17.0\,\text{y}/(\text{Gm})^{3/2}\right)r^{1.50}} \qquad (1)$$

(*b*) Solve equation (1) for the radius of the planet's orbit:

$$r = \left(\frac{T}{17.0\,\text{y}/(\text{Gm})^{3/2}}\right)^{2/3}$$

Substitute numerical values and evaluate r:

$$r = \left(\frac{6.20\,\text{y}}{17.0\,\text{y}/(\text{Gm})^{3/2}}\right)^{2/3} = \boxed{0.510\ \text{Gm}}$$

***62 •••**

Picture the Problem We can express the relationship between the period T of the pendulum, its length L, and the acceleration of gravity g as $T = CL^a g^b$ and perform dimensional analysis to find the values of a and b and, hence, the function relating these variables. Once we've performed the experiment called for in part (*b*), we can determine an experimental value for C.

(*a*) Express T as the product of L and g raised to powers a and b:

$$T = CL^a g^b \quad (1)$$

where C is a dimensionless constant.

Write this equation in dimensional form:

$$[T] = [L]^a [g]^b$$

Noting that the symbols for the dimension of the period and length of the pendulum are the same as those representing the physical quantities, substitute the dimensions to obtain:

$$T = L^a \left(\frac{L}{T^2}\right)^b$$

Because L does not appear on the left-hand side of the equation, we can write this equation as:

$$L^0 T^1 = L^{a+b} T^{-2b}$$

Equate the exponents to obtain:

$$a + b = 0 \text{ and } -2b = 1$$

Solve these equations simultaneously to find a and b:

$$a = \tfrac{1}{2} \text{ and } b = -\tfrac{1}{2}$$

Substitute in equation (1) to obtain:

$$T = CL^{1/2} g^{-1/2} = \boxed{C\sqrt{\frac{L}{g}}} \quad (2)$$

(*b*) If you use pendulums of lengths 1 m and 0.5 m; the periods should be about:

$$T(1\,\text{m}) = \boxed{2\,\text{s}}$$

and

$$T(0.5\,\text{m}) = \boxed{1.4\,\text{s}}$$

(*c*) Solve equation (2) for C:

$$C = T\sqrt{\frac{g}{L}}$$

Evaluate C with L = 1 m and T = 2 s:

$$C = (2\,\text{s})\sqrt{\frac{9.81\,\text{m/s}^2}{1\,\text{m}}} = 6.26 \approx 2\pi$$

Substitute in equation (2) to obtain:

$$T = \boxed{2\pi\sqrt{\frac{L}{g}}}$$

63 •••

Picture the Problem The weight of the earth's atmosphere per unit area is known as the atmospheric pressure. We can use this definition to express the weight w of the earth's atmosphere as the product of the atmospheric pressure and the surface area of the earth.

Using its definition, relate atmospheric pressure to the weight of the earth's atmosphere:

$$P = \frac{w}{A}$$

Solve for w:

$$w = PA$$

Relate the surface area of the earth to its radius R:

$$A = 4\pi R^2$$

Substitute to obtain:

$$w = 4\pi R^2 P$$

Substitute numerical values and evaluate w:

$$w = 4\pi(6370\,\text{km})^2\left(\frac{10^3\,\text{m}}{\text{km}}\right)^2\left(\frac{39.37\,\text{in}}{\text{m}}\right)^2\left(14.7\frac{\text{lb}}{\text{in}^2}\right) = \boxed{1.16\times10^{19}\,\text{lb}}$$

Chapter 2
Motion in One Dimension

Conceptual Problems

1 •

Determine the Concept The "average velocity" is being requested as opposed to "average speed".

The average velocity is defined as the change in position or displacement divided by the change in time.

$$v_{av} = \frac{\Delta y}{\Delta t}$$

The change in position for any "round trip" is zero by definition. So the ***average velocity*** for any round trip must also be zero.

$$v_{av} = \frac{\Delta y}{\Delta t} = \frac{0}{\Delta t} = \boxed{0}$$

***2** •

Determine the Concept The important concept here is that "average speed" is being requested as opposed to "average velocity".

Under all circumstances, including **constant acceleration**, the definition of the average speed is the ratio of the total distance traveled ($H + H$) to the total time elapsed, in this case $2H/T$. $\boxed{(d)\text{ is correct.}}$

Remarks: **Because this motion involves a round trip, if the question asked for "average velocity," the answer would be zero.**

3 •

Determine the Concept Flying with the wind, the speed of the plane relative to the ground (v_{PG}) is the sum of the speed of the wind relative to the ground (v_{WG}) and the speed of the plane relative to the air ($v_{PG} = v_{WG} + v_{PA}$). Flying into or against the wind the speed relative to the ground is the difference between the wind speed and the true air speed of the plane ($v_g = v_w – v_t$). Because the ground speed landing against the wind is smaller than the ground speed landing with the wind, it is safer to land *against* the wind.

4 •

Determine the Concept The important concept here is that $a = dv/dt$, where a is the acceleration and v is the velocity. Thus, the acceleration is positive if dv is positive; the acceleration is negative if dv is negative.

(*a*) Let's take the direction a car is moving to be the positive direction:

Because the car is moving in the direction we've chosen to be positive, its velocity is positive ($dx > 0$). If the car is braking, then its velocity is decreasing ($dv < 0$) and its acceleration (dv/dt) is negative.

(*b*) Consider a car that is moving to

Because the car is moving in the direction the right but choose the positive direction to be to the left:

opposite to that we've chosen to be positive, its velocity is negative ($dx < 0$). If the car is braking, then its velocity is increasing ($dv > 0$) and its acceleration (dv/dt) is positive.

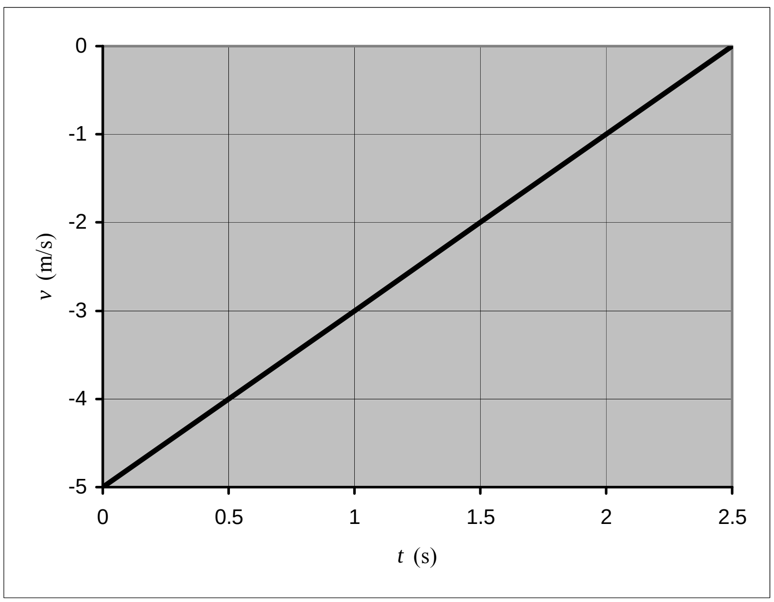
***5 •**

Determine the Concept The important concept is that when both the acceleration and the velocity are in the same direction, the speed increases. On the other hand, when the acceleration and the velocity are in opposite directions, the speed decreases.

(*a*) Because your velocity remains negative, your displacement must be *negative.*

(*b*) Define the direction of your trip as the negative direction. During the last five steps gradually slow the speed of walking, until the wall is reached.

(*c*) A graph of *v* as a function of *t* that is consistent with the conditions stated in the problem is shown below:



6 •

Determine the Concept True. We can use the definition of average velocity to express the displacement Δx as $\Delta x = v_{av}\Delta t$. Note that, if the acceleration is constant, the average velocity is also given by $v_{av} = (v_i + v_f)/2$.

7 •

Determine the Concept Acceleration is the slope of the velocity versus time curve, $a = dv/dt$; while velocity is the slope of the position versus time curve, $v = dx/dt$. The speed of an object is the magnitude of its velocity.

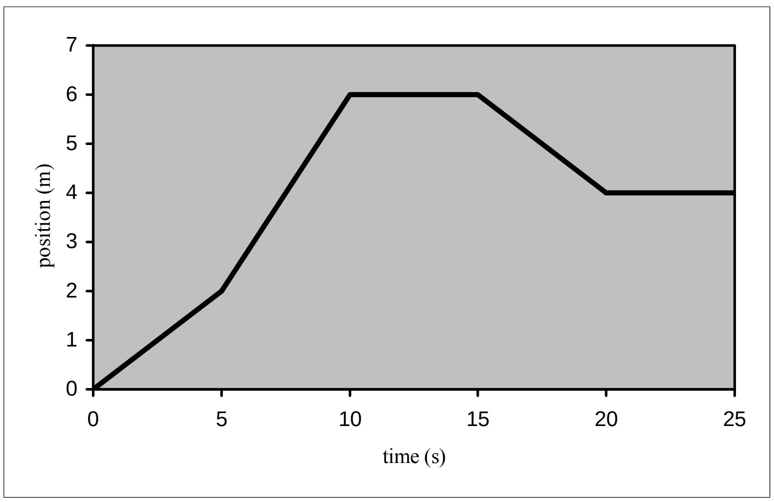
(*a*) True. Zero acceleration implies that the velocity is constant. If the velocity is constant (including zero), the speed must also be constant.

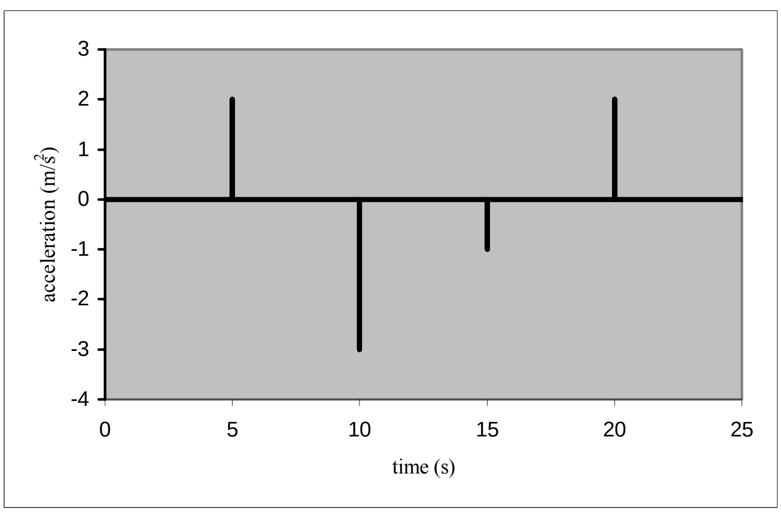
(*b*) True in one dimension.

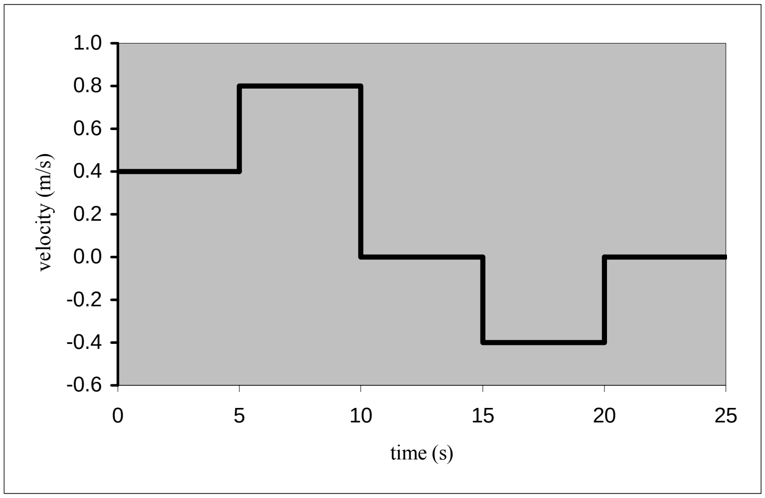
Remarks: The answer to (*b*) would be False in more than one dimension. In one dimension, if the speed remains constant, then the object cannot speed up, slow down, or reverse direction. Thus, if the speed remains constant, the velocity remains constant, which implies that the acceleration remains zero. (In more than one-dimensional motion, an object can change direction while maintaining constant speed. This constitutes a change in the direction of the velocity.) Consider a ball moving in a circle at a constant rotation rate. The speed (magnitude of the velocity) is constant while the velocity is tangent to the circle and always changing. The acceleration is always pointing inward and is certainly NOT zero.

***8** ••

Determine the Concept Velocity is the slope of the position versus time curve and acceleration is the slope of the velocity versus time curve. See the graphs below.







9 •

Determine the Concept False. The average velocity is defined (for any acceleration) as the change in position (the displacement) divided by the change in time $v_{\text{av}} = \Delta x/\Delta t$. It is always valid. If the acceleration remains constant the average velocity is also given by

$$v_{\text{av}} = \frac{v_{\text{i}} + v_{\text{f}}}{2}$$

Consider an engine piston moving up and down as an example of non-constant velocity. For one complete cycle, $v_{\text{f}} = v_{\text{i}}$ and $x_{\text{i}} = x_{\text{f}}$ so $v_{\text{av}} = \Delta x/\Delta t$ is zero. The formula involving the mean of v_{f} and v_{i} cannot be applied because the acceleration is not constant, and yields an incorrect nonzero value of v_{i}.

10 •

Determine the Concept This can occur if the rocks have different initial speeds. Ignoring air resistance, the acceleration is constant. Choose a coordinate system in which the origin is at the point of release and upward is the positive direction. From the constant-acceleration equation

$$y = y_0 + v_0 t + \tfrac{1}{2} a t^2$$

we see that the only way two objects can have the same acceleration ($-g$ in this case) and cover the same distance, $\Delta y = y - y_0$, in different times would be if the initial velocities of the two rocks were different. Actually, the answer would be the same whether or not the acceleration is constant. It is just easier to see for the special case of constant acceleration.

***11 ••**

Determine the Concept Neglecting air resistance, the balls are in free fall, each with the same free-fall acceleration, which is a constant.

At the time the second ball is released, the first ball is already moving. Thus, during any time interval their velocities will increase by exactly the same amount. What can be said about the speeds of the two balls? *The first ball will always be moving faster than the second ball.*

This being the case, what happens to the separation of the two balls while they are both falling? *Their separation increases*. $\boxed{(a)\text{ is correct.}}$

12 ••

Determine the Concept The slope of an $x(t)$ curve at any point in time represents the speed at that instant. The way the slope changes as time increases gives the sign of the acceleration. If the slope becomes less negative or more positive as time increases (as you move to the right on the time axis), then the acceleration is positive. If the slope becomes less positive or more negative, then the acceleration is negative. The slope of the slope of an $x(t)$ curve at any point in time represents the acceleration at that instant.

The slope of curve (a) is negative and becomes more negative as time increases.

Therefore, the velocity is negative and the acceleration is negative.

The slope of curve (b) is positive and constant and so the velocity is positive and constant.

Therefore, the acceleration is zero.

The slope of curve (c) is positive and decreasing.

Therefore, the velocity is positive and the acceleration is negative.

The slope of curve (d) is positive and increasing.

Therefore, the velocity and acceleration are positive. We need more information to conclude that a is constant.

The slope of curve (e) is zero.

Therefore, the velocity and acceleration are zero.

$\boxed{(d)\text{ best shows motion with constant positive acceleration.}}$

***13 •**

Determine the Concept The slope of a $v(t)$ curve at any point in time represents the acceleration at that instant. Only one curve has a constant and positive slope.
$\boxed{(b)\text{ is correct.}}$

14 •

Determine the Concept No. The word average implies an interval of time rather than an instant in time; therefore, the statement makes no sense.

***15 •**

Determine the Concept Note that the ″average velocity″ is being requested as opposed to the ″average speed.″

Yes. In any roundtrip, A to B, and back to A, the average velocity is zero.

$$v_{\text{av}(\text{A}\to\text{B}\to\text{A})}=\frac{\Delta x}{\Delta t}=\frac{\Delta x_{\text{AB}}+\Delta x_{\text{BA}}}{\Delta t}=\frac{\Delta x_{\text{AB}}+\left(-\Delta x_{\text{BA}}\right)}{\Delta t}=\frac{0}{\Delta t}=\boxed{0}$$

On the other hand, the average velocity between A and B is not generally zero.

$$v_{\text{av}(\text{A}\to\text{B})}=\frac{\Delta x_{\text{AB}}}{\Delta t}\neq\boxed{0}$$

Remarks: Consider an object launched up in the air. Its average velocity on the way up is NOT zero. Neither is it zero on the way down. However, over the round trip, it is zero.

16 •

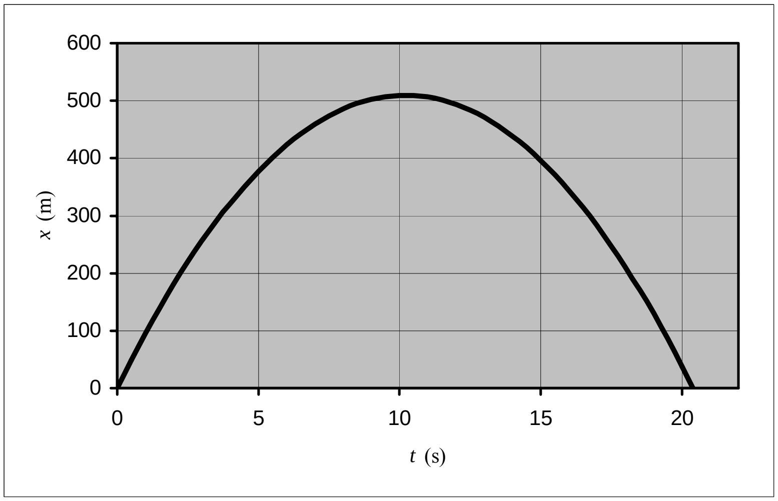
Determine the Concept An object is farthest from the origin when it is farthest from the time axis. In one-dimensional motion starting from the origin, the point located farthest from the time axis in a distance-versus-time plot is the farthest from its starting point. Because the object's initial position is at $x = 0$, point B represents the instant that the object is farthest from $x = 0$. $\boxed{(b)\text{ is correct.}}$

17 •

Determine the Concept No. If the velocity is constant, a graph of position as a function of time is linear with a constant slope equal to the velocity.

18 •

Determine the Concept Yes. The average velocity in a time interval is defined as the displacement divided by the elapsed time $v_{\text{av}}=\Delta x/\Delta t$. The fact that $v_{\text{av}} = 0$ for some time interval, Δt, implies that the displacement Δx over this interval is also zero. Because the instantaneous velocity is defined as $v=\lim_{\Delta t\to 0}\left(\Delta x/\Delta t\right)$, it follows that v must also be zero. As an example, in the following graph of x versus t, over the interval between $t = 0$ and $t \approx 21$ s, $\Delta x = 0$. Consequently, $v_{\text{av}} = 0$ for this interval. Note that the instantaneous velocity is zero only at $t \approx 10$ s.



19 ••

Determine the Concept In the one-dimensional motion shown in the figure, the velocity is a minimum when the slope of a position-versus-time plot goes to zero (i.e., the curve becomes horizontal). At these points, the slope of the position-versus-time curve is zero; therefore, the speed is zero. $\boxed{(b)\text{ is correct.}}$

***20** ••

Determine the Concept In one-dimensional motion, the velocity is the slope of a position-versus-time plot and can be either positive or negative. On the other hand, the speed is the magnitude of the velocity and can only be positive. We'll use v to denote velocity and the word "speed" for how fast the object is moving.

(*a*)
curve a: $v(t_2) < v(t_1)$
curve b: $v(t_2) = v(t_1)$
curve c: $v(t_2) > v(t_1)$
curve d: $v(t_2) < v(t_1)$

(*b*)
curve a: $\text{speed}(t_2) < \text{speed}(t_1)$
curve b: $\text{speed}(t_2) = \text{speed}(t_1)$
curve c: $\text{speed}(t_2) < \text{speed}(t_1)$
curve d: $\text{speed}(t_2) > \text{speed}(t_1)$

21 •

Determine the Concept Acceleration is the slope of the velocity-versus-time curve, $a = dv/dt$, while velocity is the slope of the position-versus-time curve, $v = dx/dt$.

(*a*) False. Zero acceleration implies that the velocity is *not changing*. The velocity could be any constant (including zero). But, if the velocity is constant and nonzero, the particle must be moving.

(*b*) True. Again, zero acceleration implies that the velocity remains constant. This means that the *x*-versus-*t* curve has a constant slope (i.e., a straight line). Note: This does not necessarily mean a zero-slope line.

22 •

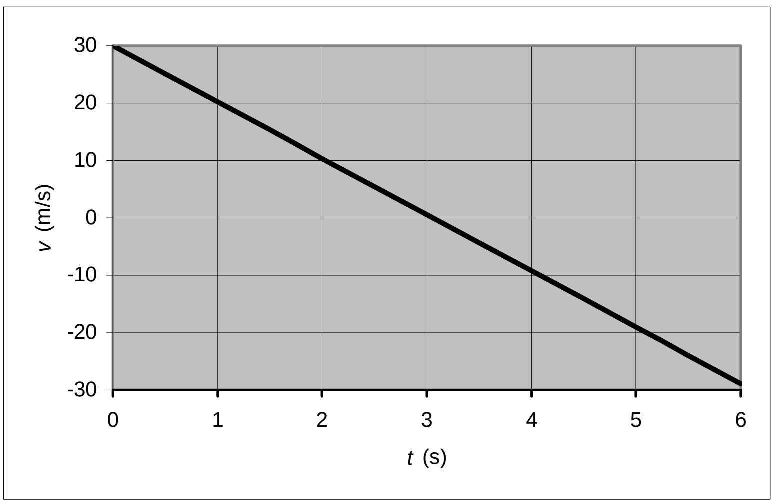
Determine the Concept Yes. If the velocity is changing the acceleration is not zero. The velocity is zero and the acceleration is nonzero any time an object is *momentarily* at rest. If the acceleration were also zero, the velocity would never change; therefore, the object would have to remain at rest.

Remarks: **It is important conceptually to note that when both the acceleration and the velocity have the same sign, the speed increases. On the other hand, when the acceleration and the velocity have opposite signs, the speed decreases.**

23 •

Determine the Concept In the absence of air resistance, the ball will experience a constant acceleration. Choose a coordinate system in which the origin is at the point of release and the upward direction is positive.

The graph shows the velocity of a ball that has been thrown straight upward with an initial speed of 30 m/s as a function of time. Note that the slope of this graph, the acceleration, is the same at every point, including the point at which $v = 0$ (at the top of its flight). Thus, $\boxed{v_{\text{top of flight}} = 0}$ and $\boxed{a_{\text{top of flight}} = -g}$.



The acceleration is the slope (–*g*).

24 •

Determine the Concept The "average speed" is being requested as opposed to "average velocity." We can use the definition of average speed as distance traveled divided by the elapsed time and expression for the average speed of an object when it is experiencing constant acceleration to express v_{av} in terms of v_0.

The average speed is defined as the total distance traveled divided by the change in time:

$$v_{av} = \frac{\text{total distance traveled}}{\text{total time}} = \frac{H + H}{T} = \frac{2H}{T}$$

Find the average speed for the upward flight of the object:

$$v_{\text{av,up}} = \frac{v_0 + 0}{2} = \frac{H}{\frac{1}{2}T}$$

Solve for H to obtain:

$$H = \tfrac{1}{4}v_0 T$$

Find the average speed for the downward flight of the object:

$$v_{\text{av,down}} = \frac{0 + v_0}{2} = \frac{H}{\frac{1}{2}T}$$

Solve for H to obtain:

$$H = \tfrac{1}{4}v_0 T$$

Substitute in our expression for v_{av} to obtain:

$$v_{\text{av}} = \frac{2\left(\frac{1}{4}v_0 T\right)}{T} = \boxed{\frac{v_0}{2}}$$

Because $v_0 \neq 0$, the average speed is not zero.

Remarks: 1) Because this motion involves a roundtrip, if the question asked for ″average velocity″, the answer would be zero. 2) Another easy way to obtain this result is take the absolute value of the velocity of the object to obtain a graph of its speed as a function of time. A simple geometric argument leads to the result we obtained above.

25 •

Determine the Concept In the absence of air resistance, the bowling ball will experience constant acceleration. Choose a coordinate system with the origin at the point of release and upward as the positive direction. Whether the ball is moving upward and slowing down, is momentarily at the top of its trajectory, or is moving downward with ever increasing velocity, its acceleration is constant and equal to the acceleration due to gravity. $\boxed{(b)\text{ is correct.}}$

26 •

Determine the Concept Both objects experience the same constant acceleration. Choose a coordinate system in which downward is the positive direction and use a constant-acceleration equation to express the position of each object as a function of time.

Using constant-acceleration equations, express the positions of both objects as functions of time:

$$x_{\text{A}} = x_{0,\text{A}} + v_0 t + \tfrac{1}{2}gt^2$$

and

$$x_{\text{B}} = x_{0,\text{B}} + v_0 t + \tfrac{1}{2}gt^2$$

where $v_0 = 0$.

Express the separation of the two objects by evaluating $x_{\text{B}} - x_{\text{A}}$:

$$x_{\text{B}} - x_{\text{A}} = x_{0,\text{B}} - x_{0.\text{A}} = 10\,\text{m}$$

and $\boxed{(d)\text{ is correct.}}$

***27** ••

Determine the Concept Because the Porsche accelerates uniformly, we need to look for a graph that represents constant acceleration. We are told that the Porsche has a constant acceleration that is positive (the velocity is increasing); therefore we must look for a velocity-versus-time curve with a positive constant slope and a nonzero intercept.

$\boxed{(c)\text{ is correct.}}$

***28** ••

Determine the Concept In the absence of air resistance, the object experiences constant acceleration. Choose a coordinate system in which the downward direction is positive.

Express the distance D that an object, released from rest, falls in time t:

$$D = \tfrac{1}{2}gt^2$$

Because the distance fallen varies with the square of the time, during the first two seconds it falls four times the distance it falls during the first second.

$$\boxed{(a)\text{ is correct.}}$$

29 ••

Determine the Concept In the absence of air resistance, the acceleration of the ball is constant. Choose a coordinate system in which the point of release is the origin and upward is the positive y direction.

The displacement of the ball halfway to its highest point is:

$$\Delta y = \frac{\Delta y_{\text{max}}}{2}$$

Using a constant-acceleration equation, relate the ball's initial and final velocities to its displacement and solve for the displacement:

$$v^2 = v_0^2 + 2a\Delta y = v_0^2 - 2g\Delta y$$

Substitute $v_0 = 0$ to determine the maximum displacement of the ball:

$$\Delta y_{\text{max}} = -\frac{v_0^2}{2(-g)} = \frac{v_0^2}{2g}$$

Express the velocity of the ball at half its maximum height:

$$v^2 = v_0^2 - 2g\Delta y = v_0^2 - 2g\frac{\Delta y_{\text{max}}}{2}$$

$$= v_0^2 - g\Delta y_{\text{max}} = v_0^2 - g\frac{v_0^2}{2g} = \frac{v_0^2}{2}$$

Solve for v:

$$v = \frac{\sqrt{2}}{2}v_0 \approx 0.707v_0$$

and $\boxed{(c)\text{ is correct.}}$

30 •

Determine the Concept As long as the acceleration remains constant the following constant-acceleration equations hold. If the acceleration is not constant, they do not, in general, give correct results except by coincidence.

$$x = x_0 + v_0t + \tfrac{1}{2}at^2 \qquad v = v_0 + at \qquad v^2 = v_0^2 + 2a\Delta x \qquad v_{\text{av}} = \frac{v_{\text{i}} + v_{\text{f}}}{2}$$

(*a*) False. From the first equation, we see that (*a*) is true if and only if the acceleration is constant.

(*b*) False. Consider a rock thrown straight up into the air. At the "top" of its flight, the velocity is zero but it is changing (otherwise the velocity would remain zero and the rock would hover); therefore the acceleration is not zero.

(*c*) True. The definition of average velocity, $v_{av} = \Delta x/\Delta t$, requires that this always be true.

***31 •**
Determine the Concept Because the acceleration of the object is constant, the constant-acceleration equations can be used to describe its motion. The special expression for average velocity for constant acceleration is $v_{av} = \dfrac{v_i + v_f}{2}$. $\boxed{(c)\text{ is correct.}}$

32 •
Determine the Concept The constant slope of the *x*-versus-*t* graph tells us that the velocity is constant and the acceleration is zero. A linear position versus time curve implies a constant velocity. The negative slope indicates a constant negative velocity. The fact that the velocity is constant implies that the acceleration is also constant and zero. $\boxed{(e)\text{ is correct.}}$

33 ••
Determine the Concept The velocity is the slope of the tangent to the curve, and the acceleration is the rate of change of this slope. Velocity is the slope of the position-versus-time curve. A parabolic $x(t)$ curve opening upward implies an increasing velocity. The acceleration is positive. $\boxed{(a)\text{ is correct.}}$

34 ••
Determine the Concept The acceleration is the slope of the tangent to the velocity as a function of time curve. For constant acceleration, a velocity-versus- time curve must be a straight line whose slope is the acceleration. Zero acceleration means that slope of $v(t)$ must also be zero. $\boxed{(c)\text{ is correct.}}$

35 ••
Determine the Concept The acceleration is the slope of the tangent to the velocity as a function of time curve. For constant acceleration, a velocity-versus- time curve must be a straight line whose slope is the acceleration. The acceleration and therefore the slope can be positive, negative, or zero. $\boxed{(d)\text{ is correct.}}$

36 ••
Determine the Concept The velocity is positive if the curve is above the $v = 0$ line (the *t* axis), and the acceleration is negative if the tangent to the curve has a negative slope. Only graphs (*a*), (*c*), and (*e*) have positive *v*. Of these, only graph (*e*) has a negative slope. $\boxed{(e)\text{ is correct.}}$

37 ••

Determine the Concept The velocity is positive if the curve is above the $v = 0$ line (the t axis), and the acceleration is negative if the tangent to the curve has a negative slope. Only graphs (b) and (d) have negative v. Of these, only graph (d) has a negative slope.

$\boxed{(d)\text{ is correct.}}$

38 ••

Determine the Concept A linear velocity-versus-time curve implies constant acceleration. The displacement from time $t = 0$ can be determined by integrating v-versus-t — that is, by finding the area under the curve. The initial velocity at $t = 0$ can be read directly from the graph of v-versus-t as the v-intercept; i.e., $v(0)$. The acceleration of the object is the slope of $v(t)$. The average velocity of the object is given by drawing a horizontal line that has the same area under it as the area under the curve. Because all of these quantities can be determined $\boxed{(e)\text{ is correct.}}$

***39** ••

Determine the Concept The velocity is the slope of a position versus time curve and the acceleration is the rate at which the velocity, and thus the slope, changes.

Velocity

(a) Negative at t_0 and t_1.
(b) Positive at t_3, t_4, t_6, and t_7.
(c) Zero at t_2 and t_5.

Acceleration

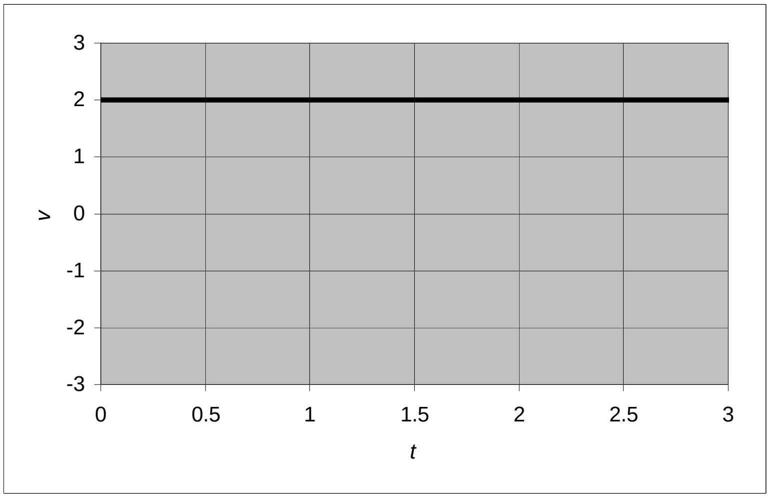
(a) Negative at t_4.
(b) Positive at t_2 and t_6.
(c) Zero at t_0, t_1, t_3, t_5, and t_7.

The acceleration is positive at points where the slope increases as you move toward the right.

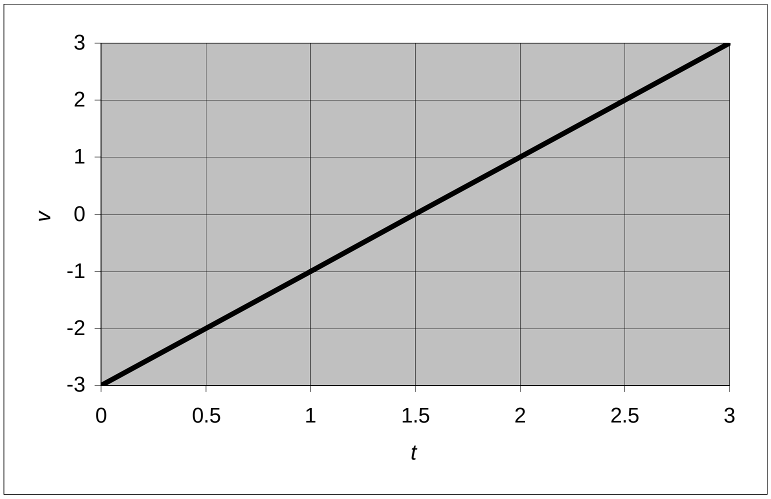
40 ••

Determine the Concept Acceleration is the slope of a velocity-versus-time curve.

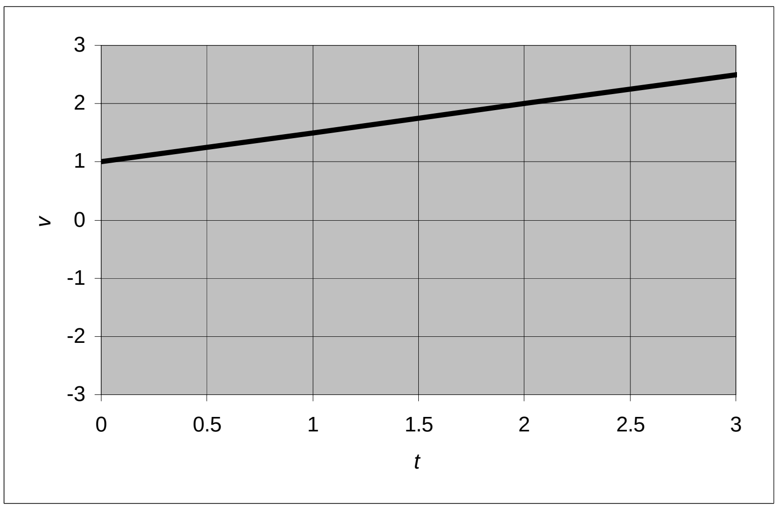
(a) Acceleration is zero and constant while velocity is not zero.



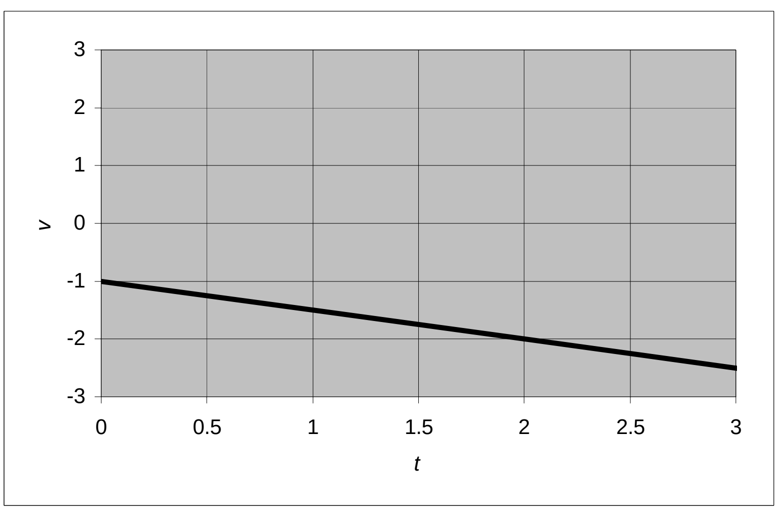
(*b*) Acceleration is constant but not zero.



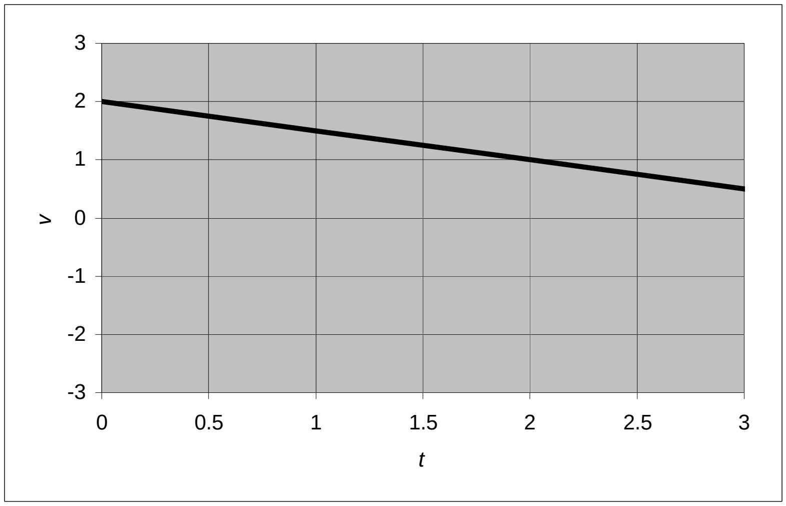
(*c*) Velocity and acceleration are both positive.



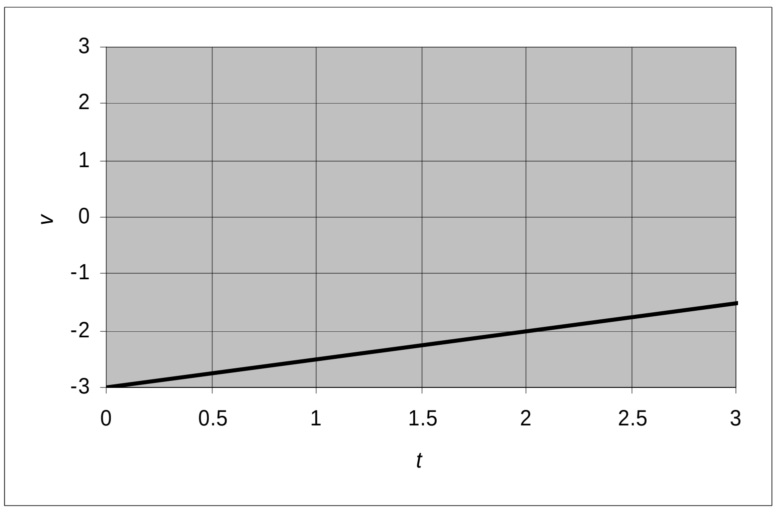
(*d*) Velocity and acceleration are both negative.



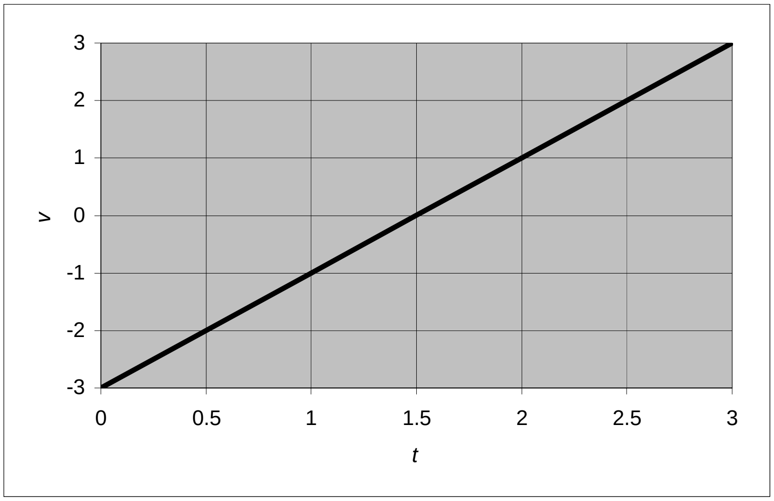
(*e*) Velocity is positive and acceleration is negative.



(*f*) Velocity is negative and acceleration is positive.



(*g*) Velocity is momentarily zero at the intercept with the *t* axis but the acceleration is not zero.



41 ••

Determine the Concept Velocity is the slope and acceleration is the slope of the slope of a position-versus-time curve. Acceleration is the slope of a velocity- versus-time curve.

(*a*) For constant velocity, *x*-versus-*t* must be a straight line; *v*-versus-*t* must be a horizontal straight line; and *a*-versus-*t* must be a straight horizontal line at $a = 0$.

(*a*), (*f*), and (*i*) are the correct answers.

(*b*) For velocity to reverse its direction *x*-versus-*t* must have a slope that changes sign and *v*-versus-*t* must cross the time axis. The acceleration cannot remain zero at all times.

(*c*) and (*d*) are the correct answers.

(*c*) For constant acceleration, *x*-versus-*t* must be a straight line or a parabola, *v*-versus-*t* must be a straight line, and *a*-versus-*t* must be a horizontal straight line.

(*a*), (*d*), (*e*), (*f*), (*h*), and (*i*) are the correct answers.

(*d*) For non-constant acceleration, *x*-versus-*t* must not be a straight line or a parabola; *v*-versus-*t* must not be a straight line, or *a*-versus-*t* must not be a horizontal straight line.

(*b*), (*c*), and (*g*) are the correct answers.

For two graphs to be mutually consistent, the curves must be consistent with the definitions of velocity and acceleration.

Graphs (*a*) and (*i*) are mutually consistent. Graphs (*d*) and (*h*) are mutually consistent. Graphs (*f*) and (*i*) are also mutually consistent.

Estimation and Approximation

42 •

Picture the Problem Assume that your heart beats at a constant rate. It does not, but the average is pretty stable.

(*a*) We will use an average pulse rate of 70 bpm for a seated (resting) adult. One's pulse rate is defined as the number of heartbeats per unit time:

$$\text{Pulse rate} = \frac{\#\text{ of heartbeats}}{\text{Time}}$$

and

$$\#\text{ of heartbeats} = \text{Pulse rate} \times \text{Time}$$

The time required to drive 1 mi at 60 mph is (1/60) h or 1 min:

$$\#\text{ of heartbeats} = (70\text{ beats/min})(1\text{ min}) = \boxed{70\text{ beats}}$$

(*b*) Express the number of heartbeats during a lifetime in terms of the pulse rate and the life span of an individual:

$$\#\text{of heartbeats} = \text{Pulse rate} \times \text{Time}$$

Assuming a 95-y life span, calculate the time in minutes:

$$\text{Time} = (95\text{ y})(365.25\text{ d/y})(24\text{ h/d})(60\text{ min/h}) = 5.00\times10^{7}\text{ min}$$

Substitute numerical values and evaluate the number of heartbeats:

$$\#\text{of heartbeats} = (70\text{ beats/min})(5.00\times10^{7}\text{ min}) = \boxed{3.50\times10^{9}\text{ beats}}$$

***43** ••

Picture the Problem In the absence of air resistance, Carlos' acceleration is constant. Because all the motion is downward, let's use a coordinate system in which downward is positive and the origin is at the point at which the fall began.

(*a***)** Using a constant-acceleration equation, relate Carlos' final velocity to his initial velocity, acceleration, and distance fallen and solve for his final velocity:

$$v^2 = v_0^2 + 2a\Delta y$$

and, because $v_0 = 0$ and $a = g$,

$$v = \sqrt{2g\Delta y}$$

Substitute numerical values and evaluate *v*:

$$v = \sqrt{2(9.81\text{ m/s}^2)(150\text{ m})} = \boxed{54.2\text{ m/s}}$$

(*b*) While his acceleration by the snow is not constant, solve the same constant- acceleration equation to get an estimate of his average acceleration:

$$a = \frac{v^2 - v_0^2}{2\Delta y}$$

Substitute numerical values and evaluate *a*:

$$a = \frac{-\left(54\,\text{m/s}^2\right)^2}{2(1.22\text{m})} = -1.20\times10^3\text{m/s}^2$$
$$= \boxed{-123g}$$

Remarks: The final velocity we obtained in part (*a*), approximately 121 mph, is about the same as the terminal velocity for an "average" man. This solution is probably only good to about 20% accuracy.

44 ••

Picture the Problem Because we're assuming that the accelerations of the skydiver and the mouse are constant to one-half their terminal velocities, we can use constant-acceleration equations to find the times required for them to reach their ″upper-bound″ velocities and their distances of fall. Let's use a coordinate system in which downward is the positive *y* direction.

(*a*) Using a constant-acceleration equation, relate the upper-bound velocity to the free-fall acceleration and the time required to reach this velocity:

$$v_{\text{upper bound}} = v_0 + g\Delta t$$
or, because $v_0 = 0$,
$$v_{\text{upper bound}} = g\Delta t$$

Solve for Δt:

$$\Delta t = \frac{v_{\text{upper bound}}}{g}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{25\,\text{m/s}}{9.81\,\text{m/s}^2} = 2.55\,\text{s}$$

Using a constant-acceleration equation, relate the skydiver's distance of fall to the elapsed time Δt:

$$\Delta y = v_0\Delta t + \tfrac{1}{2}a(\Delta t)^2$$
or, because *v*0 = 0 and $a = g$,
$$\Delta y = \tfrac{1}{2}g(\Delta t)^2$$

Substitute numerical values and evaluate Δy:

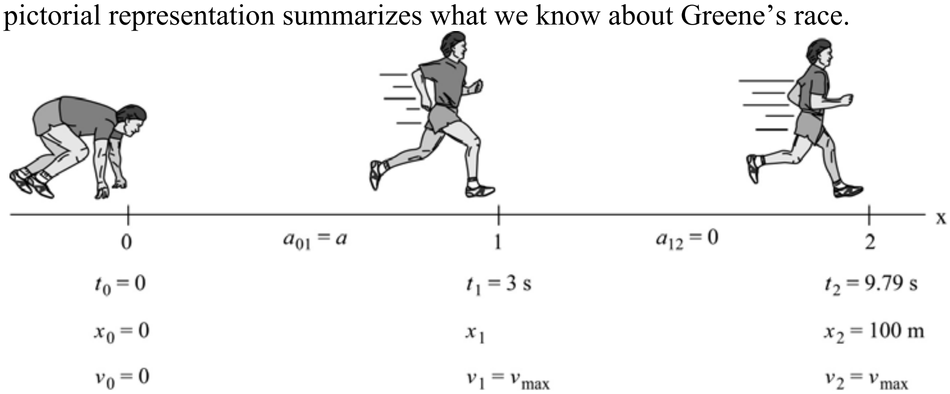
$$\Delta y = \tfrac{1}{2}\left(9.81\,\text{m/s}^2\right)(2.55\,\text{s})^2 = \boxed{31.9\,\text{m}}$$

(*b*) Proceed as in (*a*) with $v_{\text{upper bound}}$ = 0.5 m/s to obtain:

$$\Delta t = \frac{0.5\,\text{m/s}}{9.81\,\text{m/s}^2} = \boxed{0.0510\,\text{s}}$$
and
$$\Delta y = \tfrac{1}{2}\left(9.81\,\text{m/s}^2\right)(0.0510\,\text{s})^2 = \boxed{1.27\,\text{cm}}$$

45 ••

Picture the Problem This is a constant-acceleration problem. Choose a coordinate system in which the direction Greene is running is the positive x direction. During the first 3 s of the race his acceleration is positive and during the rest of the race it is zero. The pictorial representation summarizes what we know about Greene's race.



Express the total distance covered by Greene in terms of the distances covered in the two phases of his race:

$$100\,\text{m} = \Delta x_{01} + \Delta x_{12}$$

Express the distance he runs getting to his maximum velocity:

$$\Delta x_{01} = v_0 \Delta t_{01} + \tfrac{1}{2} a_{01} (\Delta t_{01})^2 = \tfrac{1}{2} a (3\,\text{s})^2$$

Express the distance covered during the rest of the race at the constant maximum velocity:

$$\Delta x_{12} = v_{max} \Delta t_{12} + \tfrac{1}{2} a_{12} (\Delta t_{12})^2 = (a \Delta t_{01}) \Delta t_{12} = a(3\,\text{s})(6.79\,\text{s})$$

Substitute for these displacements and solve for a:

$$100\,\text{m} = \tfrac{1}{2} a (3\,\text{s})^2 + a(3\,\text{s})(6.79\,\text{s})$$

and

$$a = \boxed{4.02\,\text{m/s}^2}$$

***46** ••

Determine the Concept This is a constant-acceleration problem with $a = -g$ if we take upward to be the positive direction.

At the maximum height the ball will reach, its speed will be near zero and when the ball has just been tossed in the air its speed is near its maximum value. What conclusion can you draw from the image of the ball near its maximum height?

Because the ball is moving slowly its blur is relatively short (i.e., there is less blurring).

To estimate the initial speed of the ball:

a) Estimate how far the ball being tossed moves in 1/30 s:

The ball moves about 3 ball diameters in 1/30 s.

b) Estimate the diameter of a tennis ball:

The diameter of a tennis ball is approximately 5 cm.

c) Now one can calculate the approximate distance the ball moved in 1/30 s:

$$\text{Distance traveled} = (3\text{ diameters}) \times (5\text{ cm/diameter}) = 15\text{ cm}$$

d) Calculate the average speed of the tennis ball over this distance:

$$\text{Average speed} = \frac{15\text{ cm}}{\frac{1}{30}\text{ s}} = 450\text{ cm/s} = 4.50\text{ m/s}$$

e) Because the time interval is very short, the average speed of the ball is a good approximation to its initial speed:

$\therefore\ v_0 = 4.5$ m/s

f) Finally, use the constant-acceleration equation $v^2 = v_0^2 + 2a\Delta y$ to solve for and evaluate Δy:

$$\Delta y = \frac{-v_0^2}{2a} = \frac{-(4.5\text{ m/s})^2}{2(-9.81\text{ m/s}^2)} = \boxed{1.03\text{ m}}$$

Remarks: **This maximum height is in good agreement with the height of the higher ball in the photograph.**

***47 ••**

Picture the Problem The average speed of a nerve impulse is approximately 120 m/s. Assume an average height of 1.7 m and use the definition of average speed to estimate the travel time for the nerve impulse.

Using the definition of average speed, express the travel time for the nerve impulse:

$$\Delta t = \frac{\Delta x}{v_{\text{av}}}$$

Substitute numerical values and evaluate Δ*t*:

$$\Delta t = \frac{1.7\text{ m}}{120\text{ m/s}} = \boxed{14.2\text{ ms}}$$

Speed, Displacement, and Velocity

48 •

Picture the Problem Think of the electron as traveling in a straight line at constant speed and use the definition of average speed.

(*a*) Using its definition, express the average speed of the electron:

$$\text{Average speed} = \frac{\text{distance traveled}}{\text{time of flight}} = \frac{\Delta s}{\Delta t}$$

Solve for and evaluate the time of flight:

$$\Delta t = \frac{\Delta s}{\text{Average speed}} = \frac{0.16\text{ m}}{4\times 10^{7}\text{ m/s}} = 4\times 10^{-9}\text{s} = \boxed{4.00\text{ ns}}$$

(*b*) Calculate the time of flight for an electron in a 16-cm long current carrying wire similarly.

$$\Delta t = \frac{\Delta s}{\text{Average speed}} = \frac{0.16\text{ m}}{4\times 10^{-5}\text{ m/s}} = 4\times 10^{3}\text{s} = \boxed{66.7\text{ min}}$$

***49** •

Picture the Problem In this problem the runner is traveling in a straight line but not at constant speed - first she runs, then she walks. Let's choose a coordinate system in which her initial direction of motion is taken as the positive *x* direction.

(*a*) Using the definition of average velocity, calculate the average velocity for the first 9 min:

$$v_{\text{av}} = \frac{\Delta x}{\Delta t} = \frac{2.5\text{ km}}{9\text{ min}} = \boxed{0.278\text{ km/min}}$$

(*b*) Using the definition of average velocity, calculate her average speed for the 30 min spent walking:

$$v_{\text{av}} = \frac{\Delta x}{\Delta t} = \frac{-2.5\text{ km}}{30\text{ min}} = \boxed{-0.0833\text{ km/min}}$$

(*c*) Express her average velocity for the whole trip:

$$v_{\text{av}} = \frac{\Delta x_{\text{round trip}}}{\Delta t} = \frac{0}{\Delta t} = \boxed{0}$$

(*d*) Finally, express her average speed for the whole trip:

$$\text{Average speed} = \frac{\text{distance traveled}}{\text{elapsed time}} = \frac{2(2.5\text{ km})}{30\text{ min} + 9\text{ min}} = \boxed{0.128\text{ km/min}}$$

50 •

Picture the Problem The car is traveling in a straight line but not at constant speed. Let the direction of motion be the positive *x* direction.

(*a*) Express the total displacement of the car for the entire trip:

$$\Delta x_{\text{total}} = \Delta x_1 + \Delta x_2$$

Find the displacement for each leg of the trip:

$$\Delta x_1 = v_{av,1}\Delta t_1 = (80\text{ km/h})(2.5\text{ h}) = 200\,\text{km}$$

and

$$\Delta x_2 = v_{av,2}\Delta t_2 = (40\text{ km/h})(1.5\text{ h}) = 60.0\,\text{km}$$

Add the individual displacements to get the total displacement:

$$\Delta x_{\text{total}} = \Delta x_1 + \Delta x_2 = 200\,\text{km} + 60.0\,\text{km} = \boxed{260\,\text{km}}$$

(*b*) As long as the car continues to move in the same direction, the average velocity for the total trip is given by:

$$v_{av} \equiv \frac{\Delta x_{\text{total}}}{\Delta t_{\text{total}}} = \frac{260\,\text{km}}{2.5\text{ h} + 1.5\text{ h}} = \boxed{65.0\,\text{km/h}}$$

51 •

Picture the Problem However unlikely it may seem, imagine that both jets are flying in a straight line at constant speed.

(*a*) The time of flight is the ratio of the distance traveled to the speed of the supersonic jet.

$$t_{\text{supersonic}} = \frac{s_{\text{Atlantic}}}{\text{speed}_{\text{supersonic}}} = \frac{5500\text{ km}}{2(0.340\,\text{km/s})(3600\,\text{s/h})} = \boxed{2.25\text{ h}}$$

(*b*) The time of flight is the ratio of the distance traveled to the speed of the subsonic jet.

$$t_{\text{subsonic}} = \frac{s_{\text{Atlantic}}}{\text{speed}_{\text{subsonic}}} = \frac{5500\text{ km}}{0.9(0.340\,\text{km/s})(3600\,\text{s/h})} = \boxed{4.99\,\text{h}}$$

(*c*) Adding 2 h on both the front and the back of the supersonic trip, we obtain the average speed of the supersonic flight.

$$\text{speed}_{\text{av, supersonic}} = \frac{5500\,\text{km}}{2.25\,\text{h} + 4.00\,\text{h}} = \boxed{880\,\text{km/h}}$$

(*d*) Adding 2 h on both the front and the back of the subsonic trip, we obtain the average speed of the subsonic flight.

$$\text{speed}_{\text{av, subsonic}} = \frac{5500\,\text{km}}{5.00\,\text{h} + 4.00\,\text{h}} = \boxed{611\,\text{km/h}}$$

***52** •

Picture the Problem In free space, light travels in a straight line at constant speed, *c*.

(*a*) Using the definition of average speed, solve for and evaluate the time required for light to travel from the sun to the earth:

$$\text{average speed} = \frac{s}{t}$$

and

$$t = \frac{s}{\text{average speed}} = \frac{1.5\times10^{11}\text{ m}}{3\times10^{8}\text{ m/s}}$$

$$= 500\text{ s} = \boxed{8.33\text{ min}}$$

(*b*) Proceed as in (*a*) this time using the moon-earth distance:

$$t = \frac{3.84\times10^{8}\text{ m}}{3\times10^{8}\text{ m/s}} = \boxed{1.28\text{ s}}$$

(*c*) One light-year is the distance light travels in a vacuum in one year:

$$1\text{ light - year} = 9.48\times10^{15}\text{ m} = \boxed{9.48\times10^{12}\text{ km}}$$

$$= \left(9.48\times10^{12}\text{ km}\right)\left(1\text{ mi}/1.61\text{ km}\right)$$

$$= \boxed{5.89\times10^{12}\text{ mi}}$$

53 •

Picture the Problem In free space, light travels in a straight line at constant speed, *c*.

(*a*) Using the definition of average speed (equal here to the assumed constant speed of light), solve for the time required to travel the distance to Proxima Centauri:

$$t = \frac{\text{distance traveled}}{\text{speed of light}} = \frac{4.1\times10^{16}\text{ m}}{3\times10^{8}\text{ m/s}}$$

$$= 1.37\times10^{8}\text{ s} = \boxed{4.33\text{ y}}$$

(*b*) Traveling at $10^{-4}c$, the delivery time (t_{total}) will be the sum of the time for the order to reach Hoboken and the time for the pizza to be delivered to Proxima Centauri:

$$t_{\text{total}} = t_{\text{order to be sent to Hoboken}} + t_{\text{order to be delivered}}$$

$$= 4.33\,y + \frac{4.1\times10^{13}\text{ km}}{\left(10^{-4}\right)\left(3\times10^{8}\text{ m/s}\right)}$$

$$= 4.33\text{ y} + 4.33\times10^{6}\text{ y}$$

$$\approx 4.33\times10^{6}\text{ y}$$

$$\boxed{\text{Since } 4.33\times10^{6}\text{ y} >> 1000\text{ y, Gregor does not have to pay.}}$$

54 •

Picture the Problem The time for the second 50 km is equal to the time for the entire journey less the time for the first 50 km. We can use this time to determine the average speed for the second 50 km interval from the definition of average speed.

Using the definition of average speed, find the time required for the total journey:

$$t_{\text{total}} = \frac{\text{total distance}}{\text{average speed}} = \frac{100\text{ km}}{50\text{ km/h}} = 2\text{ h}$$

Find the time required for the first 50 km:

$$t_{\text{1st 50 km}} = \frac{50\,\text{km}}{40\,\text{km/h}} = 1.25\,\text{h}$$

Find the time remaining to travel the last 50 km:

$$t_{\text{2nd 50 km}} = t_{\text{total}} - t_{\text{1st 50 km}} = 2\,\text{h} - 1.25\,\text{h} = 0.75\,\text{h}$$

Finally, use the time remaining to travel the last 50 km to determine the average speed over this distance:

$$\text{Average speed}_{\text{2nd 50 km}} = \frac{\text{distance traveled}_{\text{2nd 50 km}}}{\text{time}_{\text{2nd 50 km}}} = \frac{50\,\text{km}}{0.75\,\text{h}} = \boxed{66.7\,\text{km/h}}$$

***55 ••**

Picture the Problem Note that both the arrow and the sound travel a distance *d*. We can use the relationship between distance traveled, the speed of sound, the speed of the arrow, and the elapsed time to find the distance separating the archer and the target.

Express the elapsed time between the archer firing the arrow and hearing it strike the target:

$$\Delta t = 1\,\text{s} = \Delta t_{\text{arrow}} + \Delta t_{\text{sound}}$$

Express the transit times for the arrow and the sound in terms of the distance, *d*, and their speeds:

$$\Delta t_{\text{arrow}} = \frac{d}{\left|v_{\text{arrow}}\right|} = \frac{d}{40\,\text{m/s}}$$

and

$$\Delta t_{\text{sound}} = \frac{d}{\left|v_{\text{sound}}\right|} = \frac{d}{340\,\text{m/s}}$$

Substitute these two relationships in the expression obtained in step 1 and solve for *d*:

$$\frac{d}{40\,\text{m/s}} + \frac{d}{340\,\text{m/s}} = 1\,\text{s}$$

and $d = \boxed{35.8\,\text{m}}$

56 ••

Picture the Problem Assume both runners travel parallel paths in a straight line along the track.

(*a*) Using the definition of average speed, find the time for Marcia:

$$t_{\text{Marcia}} = \frac{\text{distance run}}{\text{Marcia's speed}} = \frac{\text{distance run}}{1.15(\text{John's speed})} = \frac{100\,\text{m}}{1.15(6\,\text{m/s})} = 14.5\,\text{s}$$

Find the distance covered by John in 14.5 s and the difference between that distance and 100 m:

$$x_{\text{John}} = (6\,\text{m/s})(14.5\,\text{s}) = 87.0\,\text{m}$$

and Marcia wins by

$$100\,\text{m} - 87\,\text{m} = \boxed{13.0\,\text{m}}$$

(*b*) Using the definition of average speed, find the time required by John to complete the 100-m run:

$$t_{\text{John}} = \frac{\text{distance run}}{\text{John's speed}} = \frac{100\,\text{m}}{6\,\text{m/s}} = 16.7\,\text{s}$$

Marsha wins by 16.7 s – 14.5 s = 2.2 s

Alternatively, the time required by John to travel the last 13.0 m is

$(13\text{ m})/(6\text{ m/s}) = \boxed{2.17\,\text{s}}$

57 •

Picture the Problem The average velocity in a time interval is defined as the displacement divided by the time elapsed; that is $v_{\text{av}} = \Delta x/\Delta t$.

(*a*) $\Delta x_a = 0$

$$v_{\text{av}} = \boxed{0}$$

(*b*) $\Delta x_b = 1$ m and $\Delta t_b = 3$ s

$$v_{\text{av}} = \boxed{0.333\,\text{m/s}}$$

(*c*) $\Delta x_c = -6$ m and $\Delta t_c = 3$ s

$$v_{\text{av}} = \boxed{-2.00\,\text{m/s}}$$

(*d*) $\Delta x_d = 3$ m and $\Delta t_d = 3$ s

$$v_{\text{av}} = \boxed{1.00\,\text{m/s}}$$

58 ••

Picture the Problem In free space, light travels in a straight line at constant speed *c*. We can use Hubble's law to find the speed of the two planets.

(*a*) Using Hubble's law, calculate the speed of the first galaxy:

$$v_{\text{a}} = \left(5\times10^{22}\,\text{m}\right)\left(1.58\times10^{-18}\,\text{s}^{-1}\right) = \boxed{7.90\times10^{4}\,\text{m/s}}$$

(*b*) Using Hubble's law, calculate the speed of the second galaxy:

$$v_{\text{b}} = \left(2\times10^{25}\,\text{m}\right)\left(1.58\times10^{-18}\,\text{s}^{-1}\right) = \boxed{3.16\times10^{7}\,\text{m/s}}$$

(*c*) Using the relationship between distance, speed, and time for both galaxies, determine how long ago they were both located at the same place as the earth:

$$t = \frac{r}{v} = \frac{r}{rH} = \frac{1}{H} = 6.33\times10^{17}\,\text{s} = 20.1\times10^{9}\,\text{y} = \boxed{20.1\,\text{billion years}}$$

***59 ••**

Picture the Problem Ignoring the time intervals during which members of this relay time get up to their running speeds, their accelerations are zero and their average speed can be found from its definition.

Using its definition, relate the average speed to the total distance traveled and the elapsed time:

$$|v_{av}| = \frac{\text{distance traveled}}{\text{elapsed time}}$$

Express the time required for each animal to travel a distance L:

$$t_{cheetah} = \frac{L}{v_{cheetah}},$$

$$t_{falcon} = \frac{L}{v_{falcon}},$$

and

$$t_{sailfish} = \frac{L}{v_{sailfish}}$$

Express the total time, Δt:

$$\Delta t = L\left(\frac{1}{v_{cheetah}} + \frac{1}{v_{falcon}} + \frac{1}{v_{sailfish}}\right)$$

Use the total distance traveled by the relay team and the elapsed time to calculate the average speed:

$$|v_{av}| = \frac{3L}{L\left(\frac{1}{113\,\text{km/h}} + \frac{1}{161\,\text{km/h}} + \frac{1}{105\,\text{km/h}}\right)} = \boxed{122\,\text{km/h}}$$

Calculate the average of the three speeds:

$$\text{Average}_{\text{three speeds}} = \frac{113\,\text{km/h} + 161\,\text{km/h} + 105\,\text{km/h}}{3} = \boxed{126\,\text{km/h} = 1.03 v_{av}}$$

60 ••

Picture the Problem Perhaps the easiest way to solve this problem is to think in terms of the relative velocity of one car relative to the other. Solve this problem from the reference frame of car A. In this frame, car A remains at rest.

Find the velocity of car B relative to car A:

$$v_{rel} = v_B - v_A = (110 - 80)\text{ km/h} = 30\text{ km/h}$$

Find the time before car B reaches car A:

$$\Delta t = \frac{\Delta x}{v_{rel}} = \frac{45\,\text{km}}{30\,\text{km/h}} = 1.5\,\text{h}$$

Find the distance traveled, relative to the road, by car A in 1.5 h:

$$d = (1.5\,\text{h})(80\,\text{km/h}) = \boxed{120\,\text{km}}$$

***61 ••**

Picture the Problem One way to solve this problem is by using a graphing calculator to plot the positions of each car as a function of time. Plotting these positions as functions of time allows us to visualize the motion of the two cars relative to the (fixed) ground. More importantly, it allows us to see the motion of the two cars relative to each other. We can, for example, tell how far apart the cars are at any given time by determining the length of a vertical line segment from one curve to the other.

(*a*) Letting the origin of our coordinate system be at the intersection, the position of the slower car, $x_1(t)$, is given by:

$x_1(t) = 20t$
where x_1 is in meters if t is in seconds.

Because the faster car is also moving at a constant speed, we know that the position of this car is given by a function of the form:

$x_2(t) = 30t + b$

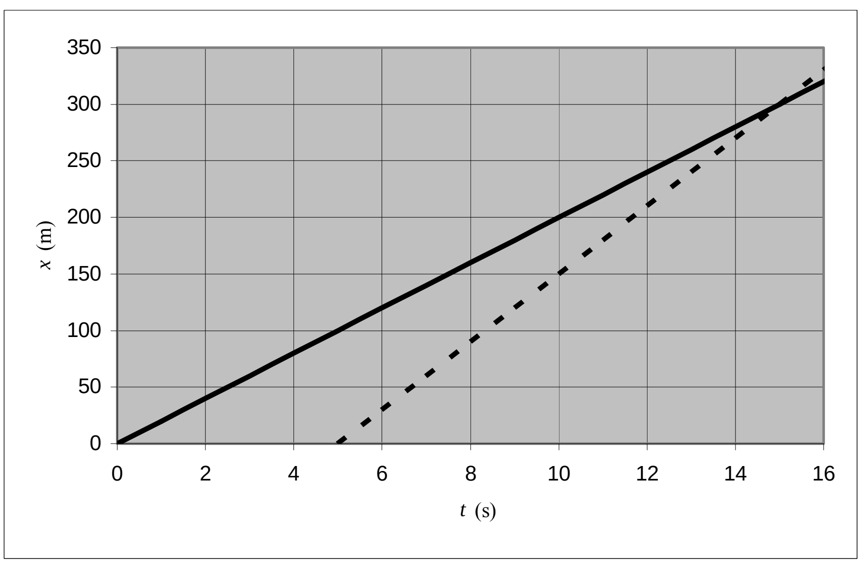
We know that when t = 5 s, this second car is at the intersection (i.e., $x_2(5\text{ s}) = 0$). Using this information, you can convince yourself that:

$b = -150$ m

Thus, the position of the faster car is given by:

$$x_2(t) = 30t - 150$$

One can use a graphing calculator, graphing paper, or a spreadsheet to obtain the graphs of $x_1(t)$ (the solid line) and $x_2(t)$ (the dashed line) shown below:



(*b*) Use the time coordinate of the intersection of the two lines to determine the time at which the second car overtakes the first:

From the intersection of the two lines, one can see that the second car will "overtake" (catch up to) the first car at $\boxed{t = 15\text{ s}}$.

(*c*) Use the position coordinate of the intersection of the two lines to determine the distance from the intersection at which the second car catches up to the first car:

From the intersection of the two lines, one can see that the distance from the intersection is $\boxed{300\text{ m}}$.

(*d*) Draw a vertical line from $t = 5$ s to the red line and then read the position coordinate of the intersection of this line and the red line to determine the position of the first car when the second car went through the intersection:

From the graph, when the second car passes the intersection, the first car was $\boxed{100\text{ m ahead}}$.

62 •

Picture the Problem Sally's velocity relative to the ground (v_{SG}) is the sum of her velocity relative to the moving belt (v_{SB}) and the velocity of the belt relative to the ground (v_{BG}). Joe's velocity relative to the ground is the same as the velocity of the belt relative to the ground. Let D be the length of the moving sidewalk.

Express D in terms of v_{BG} (Joe's speed relative to the ground):

$$D = (2\text{ min})v_{BG}$$

Solve for v_{BG}:

$$v_{BG} = \frac{D}{2\text{ min}}$$

Express D in terms of $v_{BG} + v_{SG}$ (Sally's speed relative to the ground):

$$D = (1\text{ min})(v_{BG} + v_{SG}) = (1\text{ min})\left(\frac{D}{2\text{ min}} + v_{SG}\right)$$

Solve for v_{SG}:

$$v_{SG} = \frac{D}{1\text{ min}} - \frac{D}{2\text{ min}} = \frac{D}{2\text{ min}}$$

Express D in terms of $v_{BG} + 2v_{SB}$ (Sally's speed for a fast walk relative to the ground):

$$D = t_f(v_{BG} + 2v_{SB}) = t_f\left(\frac{D}{2\text{ min}} + \frac{2D}{2\text{ min}}\right) = t_f\left(\frac{3D}{2\text{ min}}\right)$$

Solve for t_f as time for Sally's fast walk:

$$t_f = \frac{2\text{ min}}{3} = \boxed{40.0\text{ s}}$$

63 ••

Picture the Problem The speed of Margaret's boat relative to the riverbank ($\left|v_{\text{BR}}\right|$) is the sum or difference of the speed of her boat relative to the water ($\left|v_{\text{BW}}\right|$) and the speed of the water relative to the riverbank ($\left|v_{WR}\right|$), depending on whether she is heading with or against the current. Let D be the distance to the marina.

Express the total time for the trip:

$$t_{\text{tot}} = t_1 + t_2$$

Express the times of travel with the motor running in terms of D, $\left|v_{WR}\right|$ and $\left|v_{\text{BW}}\right|$:

$$t_1 = \frac{D}{\left|v_{\text{BW}}\right| - \left|v_{\text{WR}}\right|} = 4\,\text{h}$$

and

$$t_2 = \frac{D}{\left|v_{\text{BW}}\right| + \left|v_{\text{WR}}\right|}$$

Express the time required to drift distance D and solve for $\left|v_{\text{WR}}\right|$:

$$t_3 = \frac{D}{\left|v_{\text{WR}}\right|} = 8\,\text{h}$$

and

$$\left|v_{\text{WR}}\right| = \frac{D}{8\,\text{h}}$$

From $t_1 = 4$ h, find $\left|v_{\text{BW}}\right|$:

$$\left|v_{\text{BW}}\right| = \frac{D}{4\ \text{h}} + \left|v_{\text{WR}}\right| = \frac{D}{4\ \text{h}} + \frac{D}{8\ \text{h}} = \frac{3D}{8\ \text{h}}$$

Solve for t_2:

$$t_2 = \frac{D}{\left|v_{\text{BW}}\right| + \left|v_{\text{WR}}\right|} = \frac{D}{\frac{3D}{8\,\text{h}} + \frac{D}{8\,\text{h}}} = 2\,\text{h}$$

Add t_1 and t_2 to find the total time:

$$t_{\text{tot}} = t_1 + t_2 = \boxed{6\,\text{h}}$$

Acceleration

64 •

Picture the Problem In part (*a*), we can apply the definition of average acceleration to find a_{av}. In part (*b*), we can find the change in the car's velocity in one second and add this change to its velocity at the beginning of the interval to find its speed one second later.

(*a*) Apply the definition of average acceleration:

$$a_{\text{av}} = \frac{\Delta v}{\Delta t} = \frac{80.5\,\text{km/h} - 48.3\,\text{km/h}}{3.7\,\text{s}}$$

$$= 8.70\frac{\text{km}}{\text{h}\cdot\text{s}}$$

Convert to m/s²:

$$a_{av} = \left(8.70\times10^3\,\frac{\text{m}}{\text{h}\cdot\text{s}}\right)\left(\frac{1\,\text{h}}{3600\,\text{s}}\right) = \boxed{2.42\,\text{m/s}^2}$$

(*b*) Express the speed of the car at the end of 4.7 s:

$$v(4.7\,\text{s}) = v(3.7\,\text{s}) + \Delta v_{1\,\text{s}} = 80.5\,\text{km/h} + \Delta v_{1\,\text{s}}$$

Find the change in the speed of the car in 1 s:

$$\Delta v = a_{av}\Delta t = \left(8.70\,\frac{\text{km}}{\text{h}\cdot\text{s}}\right)(1\,\text{s}) = 8.70\,\text{km/h}$$

Substitute and evaluate v(4.7 s):

$$v(4.7\,\text{s}) = 80.5\,\text{km/h} + 8.7\,\text{km/h} = \boxed{89.2\,\text{km/h}}$$

65 •

Picture the Problem Average acceleration is defined as $a_{av} = \Delta v/\Delta t$.

The average acceleration is defined as the change in velocity divided by the change in time:

$$a_{av} = \frac{\Delta v}{\Delta t} = \frac{(-1\text{m/s}) - (5\text{m/s})}{(8\text{s}) - (5\text{s})} = \boxed{-2.00\,\text{m/s}^2}$$

66 ••

Picture the Problem The important concept here is the difference between average acceleration and instantaneous acceleration.

(*a*) The average acceleration is defined as the change in velocity divided by the change in time:

$a_{av} = \Delta v/\Delta t$

Determine v at t = 3 s, t = 4 s, and t = 5 s:

v(3 s) = 17 m/s
v(4 s) = 25 m/s
v(5 s) = 33 m/s

Find a_{av} for the two 1-s intervals:

a_{av}(3 s to 4 s) = (25 m/s – 17 m/s)/(1 s) = 8 m/s²

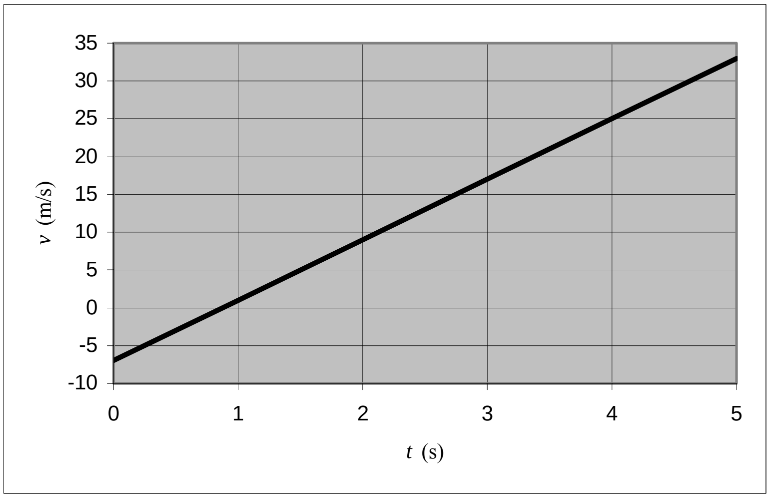
and

a_{av}(4 s to 5 s) = (33 m/s – 25 m/s)/(1 s) = 8 m/s²

The instantaneous acceleration is defined as the time derivative of the velocity or the slope of the velocity-versus-time curve:

$$a = \frac{dv}{dt} = \boxed{8.00\,\text{m/s}^2}$$

(*b*) The given function was used to plot the following spreadsheet-graph of *v*-versus-*t*:



67 ••

Picture the Problem We can closely approximate the instantaneous velocity by the average velocity in the limit as the time interval of the average becomes small. This is important because all we can ever obtain from any measurement is the average velocity, v_{av}, which we use to approximate the instantaneous velocity v.

(*a*) Find $x(4\text{ s})$ and $x(3\text{ s})$:

$x(4\text{ s}) = (4)^2 - 5(4) + 1 = -3\text{ m}$
and
$x(3\text{ s}) = (3)^2 - 5(3) + 1 = -5\text{ m}$

Find Δx:

$$\Delta x = x(4\text{ s}) - x(3\text{ s}) = (-3\text{ m}) - (-5\text{ m}) = \boxed{2\text{ m}}$$

Use the definition of average velocity:

$$v_{av} = \Delta x/\Delta t = (2\text{ m})/(1\text{ s}) = \boxed{2\text{ m/s}}$$

(*b*) Find $x(t + \Delta t)$:

$$x(t+\Delta t) = (t+\Delta t)^2 - 5(t+\Delta t) + 1 = (t^2 + 2t\Delta t + (\Delta t)^2) - 5(t+\Delta t) + 1$$

Express $x(t + \Delta t) - x(t) = \Delta x$:

$$\Delta x = \boxed{(2t-5)\Delta t + (\Delta t)^2}$$

where Δx is in meters if t is in seconds.

(*c*) From (*b*) find $\Delta x/\Delta t$ as $\Delta t \to 0$:

$$\frac{\Delta x}{\Delta t} = \frac{(2t-5)\Delta t + (\Delta t)^2}{\Delta t} = 2t - 5 + \Delta t$$

and

$$v = \lim_{\Delta t \to 0}(\Delta x / \Delta t) = \boxed{2t - 5}$$

where v is in m/s if t is in seconds.

Alternatively, we can take the derivative of $x(t)$ with respect to time to obtain the instantaneous velocity.

$$v(t) = dx(t)/dt = \frac{d}{dt}(at^2 + bt + 1)$$
$$= 2at + b = 2t - 5$$

***68 ••**

Picture the Problem The instantaneous velocity is dx/dt and the acceleration is dv/dt.

Using the definitions of instantaneous velocity and acceleration, determine v and a:

$$v = \frac{dx}{dt} = \frac{d}{dt}\left[At^2 - Bt + C\right] = 2At - B$$

and

$$a = \frac{dv}{dr} = \frac{d}{dt}\left[2At - B\right] = 2A$$

Substitute numerical values for A and B and evaluate v and a:

$$v = 2(8\text{m/s}^2)t - 6\text{ m/s}$$
$$= \boxed{(16\text{ m/s}^2)t - 6\text{m/s}}$$

and

$$a = 2(8\text{ m/s}^2) = \boxed{16.0\text{ m/s}^2}$$

69 ••

Picture the Problem We can use the definition of average acceleration ($a_{av} = \Delta v/\Delta t$) to find a_{av} for the three intervals of constant acceleration shown on the graph.

(*a*) Using the definition of average acceleration, find a_{av} for the interval AB:

$$a_{\text{av, AB}} = \frac{15\text{ m/s} - 5\text{ m/s}}{3\text{ s}} = \boxed{3.33\text{ m/s}^2}$$

Find a_{av} for the interval BC:

$$a_{\text{av, BC}} = \frac{15\text{ m/s} - 15\text{ m/s}}{3\text{ s}} = \boxed{0}$$

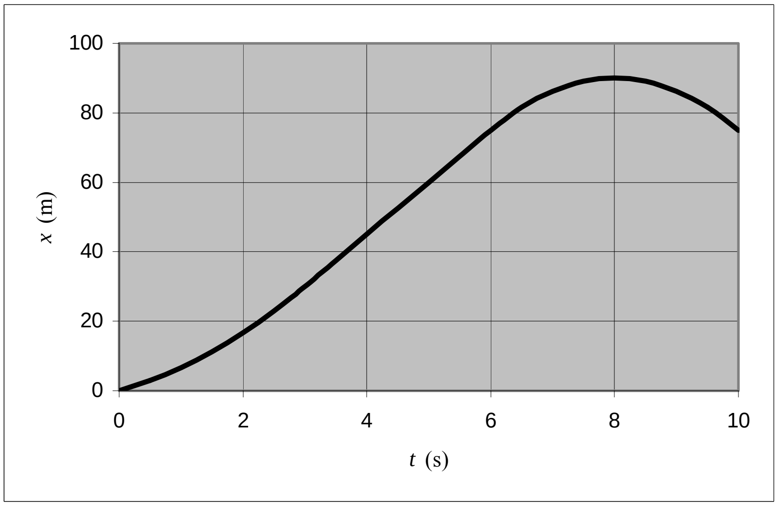
Find a_{av} for the interval CE:

$$a_{\text{av, CE}} = \frac{-15\text{ m/s} - 15\text{m/s}}{4\text{ s}} = \boxed{-7.50\text{m/s}^2}$$

(*b*) Use the formulas for the areas of trapezoids and triangles to find the area under the graph of v as a function of t.

$$\Delta x = (\Delta x)_{A\to B} + (\Delta x)_{B\to C} + (\Delta x)_{C\to D} + (\Delta x)_{D\to E}$$
$$= \tfrac{1}{2}(5\,\text{m/s} + 15\,\text{m/s})(3\,\text{s}) + (15\,\text{m/s})(3\,\text{s}) + \tfrac{1}{2}(15\,\text{m/s})(2\,\text{s}) + \tfrac{1}{2}(-15\,\text{m/s})(2\,\text{s})$$
$$= \boxed{75.0\,\text{m}}$$

(*c*) The graph of displacement, *x*, as a function of time, *t*, is shown in the following figure. In the region from B to C the velocity is constant so the *x*- versus-*t* curve is a straight line.



(*d*) Reading directly from the figure, we can find the time when the particle is moving the slowest.

$\boxed{\text{At point D, } t = 8\text{ s, the graph crosses the time axis; therefore, } v = 0.}$

Constant Acceleration and Free-Fall

***70** •

Picture the Problem Because the acceleration is constant (–*g*) we can use a constant-acceleration equation to find the height of the projectile.

Using a constant-acceleration equation, express the height of the object as a function of its initial velocity, the acceleration due to gravity, and its displacement:

$$v^2 = v_0^2 + 2a\Delta y$$

Solve for $\Delta y_{max} = h$:

Because $v(h) = 0$,

$$h = \frac{-v_0^2}{2(-g)} = \frac{v_0^2}{2g}$$

From this expression for *h* we see that the maximum height attained is proportional to the square of the launch speed:

$$h \propto v_0^2$$

Therefore, doubling the initial speed gives four times the height:

$$h_{2v_0} = \frac{(2v_0)^2}{2g} = 4\left(\frac{v_0^2}{2g}\right) = 4h_{v_0}$$

and $\boxed{(a)\,\text{is correct.}}$

71 •

Picture the Problem Because the acceleration of the car is constant we can use constant-acceleration equations to describe its motion.

(*a*) Using a constant-acceleration equation, relate the velocity to the acceleration and the time:

$$v = v_0 + at = 0 + (8\,\text{m/s}^2)(10\,\text{s})$$
$$= \boxed{80.0\,\text{m/s}}$$

(*b*) sing a constant-acceleration equation, relate the displacement to the acceleration and the time:

$$\Delta x = x - x_0 = v_0 t + \frac{a}{2}t^2$$

Substitute numerical values and evaluate Δx:

$$\Delta x = \frac{1}{2}(8\,\text{m/s}^2)(10\,\text{s})^2 = \boxed{400\,\text{m}}$$

(*c*) Use the definition of v_{av}:

$$v_{av} = \frac{\Delta x}{\Delta t} = \frac{400\,\text{m}}{10\,\text{s}} = \boxed{40.0\,\text{m/s}}$$

Remarks: Because the area under a velocity-versus-time graph is the displacement of the object, we could solve this problem graphically.

72 •

Picture the Problem Because the acceleration of the object is constant we can use constant-acceleration equations to describe its motion.

Using a constant-acceleration equation, relate the velocity to the acceleration and the displacement:

$$v^2 = v_0^2 + 2a\,\Delta x$$

Solve for and evaluate the displacement:

$$\Delta x = \frac{v^2 - v_0^2}{2a} = \frac{(15^2 - 5^2)\text{m}^2/\text{s}^2}{2(2\,\text{m/s}^2)}$$
$$= \boxed{50.0\,\text{m}}$$

***73** •

Picture the Problem Because the acceleration of the object is constant we can use constant-acceleration equations to describe its motion.

Using a constant-acceleration equation, relate the velocity to the acceleration and the displacement:

$$v^2 = v_0^2 + 2a\,\Delta x$$

Solve for the acceleration:

$$a=\frac{v^2-v_0^2}{2\Delta x}$$

Substitute numerical values and evaluate *a*:

$$a=\frac{\left(15^2-10^2\right)\text{m}^2/\text{s}^2}{2(4\,\text{m})}=\boxed{15.6\,\text{m/s}^2}$$

74 •

Picture the Problem Because the acceleration of the object is constant we can use constant-acceleration equations to describe its motion.

Using a constant-acceleration equation, relate the velocity to the acceleration and the displacement:

$$v^2=v_0^2+2\,a\,\Delta x$$

Solve for and evaluate *v*:

$$v=\sqrt{(1\,\text{m/s})^2+2\left(4\,\text{m/s}^2\right)(1\,\text{m})}$$
$$=\boxed{3.00\,\text{m/s}}$$

Using the definition of average acceleration, solve for the time:

$$t=\frac{\Delta v}{a_{\text{av}}}=\frac{3\,\text{m/s}-1\,\text{m/s}}{4\,\text{m/s}^2}=\boxed{0.500\,\text{s}}$$

75 ••

Picture the Problem In the absence of air resistance, the ball experiences constant acceleration. Choose a coordinate system with the origin at the point of release and the positive direction upward.

(*a*) Using a constant-acceleration equation, relate the displacement of the ball to the acceleration and the time:

$$\Delta y=v_0t+\tfrac{1}{2}at^2$$

Setting Δy = 0 (the displacement for a round trip), solve for and evaluate the time required for the ball to return to its starting position:

$$t_{\text{round trip}}=\frac{2v_0}{g}=\frac{2(20\,\text{m/s})}{9.81\,\text{m/s}^2}=\boxed{4.08\,\text{s}}$$

(*b*) Using a constant-acceleration equation, relate the final speed of the ball to its initial speed, the acceleration, and its displacement:

$$v_{\text{top}}^2=v_0^2+2a\Delta y$$

or, because $v_{\text{top}}=0$ and $a=-g$,

$$0=v_0^2+2(-g)H$$

Solve for and evaluate *H*:

$$H=\frac{v_0^2}{2g}=\frac{(20\,\text{m/s})^2}{2\left(9.81\,\text{m/s}^2\right)}=\boxed{20.4\,\text{m}}$$

(*c*) Using the same constant-acceleration equation with which we began part (*a*), express the displacement as a function of time:

$$\Delta y=v_0t+\tfrac{1}{2}at^2$$

Substitute numerical values to obtain:

$$15\,\text{m} = (20\,\text{m/s})t - \left(\frac{9.81\,\text{m/s}^2}{2}\right)t^2$$

Solve the quadratic equation for the times at which the displacement of the ball is 15 m:

The solutions are $t = \boxed{0.991\,\text{s}}$ (this corresponds to passing 15 m on the way up) and $t = \boxed{3.09\,\text{s}}$ (this corresponds to passing 15 m on the way down).

76 ••

Picture the Problem This is a multipart constant-acceleration problem using two different constant accelerations. We'll choose a coordinate system in which downward is the positive direction and apply constant-acceleration equations to find the required times.

(*a*) Using a constant-acceleration equation, relate the time for the slide to the distance of fall and the acceleration:

$$\Delta y = y - y_0 = h - 0 = v_0 t_1 + \tfrac{1}{2}at_1^2$$

or, because $v_0 = 0$,

$$h = \tfrac{1}{2}at_1^2$$

Solve for t_1:

$$t_1 = \sqrt{\frac{2h}{g}}$$

Substitute numerical values and evaluate t_1:

$$t_1 = \sqrt{\frac{2(460\,\text{m})}{9.81\,\text{m/s}^2}} = \boxed{9.68\,\text{s}}$$

(*b*) Using a constant-acceleration equation, relate the velocity at the bottom of the mountain to the acceleration and time:

$$v_1 = v_0 + a_1 t_1$$

or, because $v_0 = 0$ and $a_1 = g$,

$$v_1 = g t_1$$

Substitute numerical values and evaluate v_1:

$$v_1 = (9.81\,\text{m/s}^2)(9.68\,\text{s}) = \boxed{95.0\,\text{m/s}}$$

(*c*) Using a constant-acceleration equation, relate the time required to stop the mass of rock and mud to its average speed and the distance it slides:

$$\Delta t = \frac{\Delta x}{v_{\text{av}}}$$

Because the acceleration is constant:

$$v_{\text{av}} = \frac{v_1 + v_{\text{f}}}{2} = \frac{v_1 + 0}{2} = \frac{v_1}{2}$$

Substitute to obtain:

$$\Delta t = \frac{2\Delta x}{v_1}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{2(8000\,\text{m})}{95.0\,\text{m/s}} = \boxed{168\,\text{s}}$$

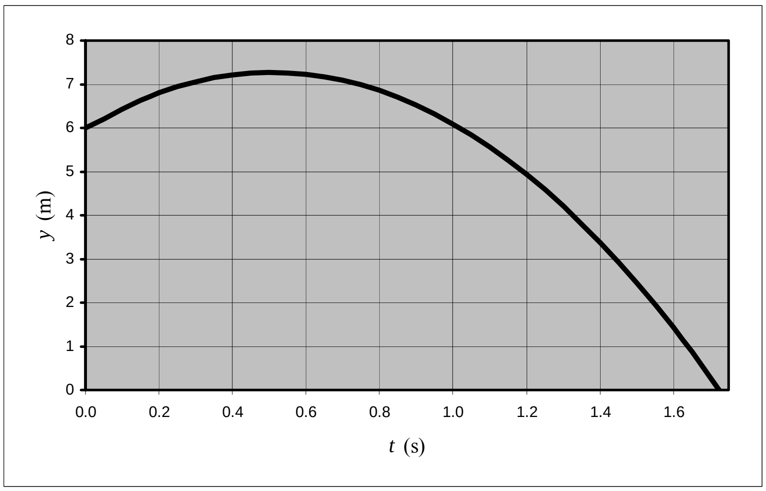
***77** ••

Picture the Problem In the absence of air resistance, the brick experiences constant acceleration and we can use constant-acceleration equations to describe its motion. Constant acceleration implies a parabolic position-versus-time curve.

(*a*) Using a constant-acceleration equation, relate the position of the brick to its initial position, initial velocity, acceleration, and time into its fall:

$$y = y_0 + v_0 t + \tfrac{1}{2}(-g)t^2$$
$$= 6\,\text{m} + (5\,\text{m/s})t - (4.91\,\text{m/s}^2)t^2$$

The following graph of $y = 6\,\text{m} + (5\,\text{m/s})t - (4.91\,\text{m/s}^2)t^2$ was plotted using a spreadsheet program:



(*b*) Relate the greatest height reached by the brick to its height when it falls off the load and the additional height it rises Δy_{max}:

$$h = y_0 + \Delta y_{max}$$

Using a constant-acceleration equation, relate the height reached by the brick to its acceleration and initial velocity:

$$v_{top}^2 = v_0^2 + 2(-g)\Delta y_{max}$$

or, because $v_{top} = 0$,

$$0 = v_0^2 + 2(-g)\Delta y_{max}$$

Solve for Δy_{max}:

$$\Delta y_{max} = \frac{v_0^2}{2g}$$

Substitute numerical values and evaluate Δy_{max}:

$$\Delta y_{max} = \frac{(5\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)} = 1.27\,\text{m}$$

Substitute to obtain:

$$h = y_0 + \Delta y_{max} = 6\,\text{m} + 1.27\,\text{m} = \boxed{7.27\,\text{m}}$$

Note: The graph shown above confirms this result.

(*c*) Using the quadratic formula, solve for *t* in the equation obtained in part (*a*):

$$t = \frac{-v_0 \pm \sqrt{v_0^2 - 4\left(\frac{-g}{2}\right)(-\Delta y)}}{2\left(\frac{-g}{2}\right)}$$

$$= \left(\frac{v_0}{g}\right)\left(1 \pm \sqrt{1 - \frac{2g(\Delta y)}{v_0^2}}\right)$$

With y_{bottom} = 0 and y_o = 6 m or Δy = –6 m, we obtain:

$t = \boxed{1.73\,\text{s}}$ and t = –0.708 s. Note: The second solution is nonphysical.

(*d*) Using a constant-acceleration equation, relate the speed of the brick on impact to its acceleration and displacement, and solve for its speed:

$$v = \sqrt{2gh}$$

Substitute numerical values and evaluate *v*:

$$v = \sqrt{2(9.81\,\text{m/s}^2)(7.27\,\text{m})} = \boxed{11.9\,\text{m/s}}$$

78 ••

Picture the Problem In the absence of air resistance, the acceleration of the bolt is constant. Choose a coordinate system in which upward is positive and the origin is at the bottom of the shaft (y = 0).

(*a*) Using a constant-acceleration equation, relate the position of the bolt to its initial position, initial velocity, and fall time:

$$y_{bottom} = 0 = y_0 + v_0 t + \tfrac{1}{2}(-g)t^2$$

Solve for the position of the bolt when it came loose:

$$y_0 = -v_0 t + \tfrac{1}{2} g t^2$$

Substitute numerical values and evaluate y_0:

$$y_0 = -(6\,\text{m/s})(3\,\text{s}) + \tfrac{1}{2}(9.81\,\text{m/s}^2)(3\,\text{s})^2 = \boxed{26.1\,\text{m}}$$

(*b*) Using a constant-acceleration equation, relate the speed of the bolt to its initial speed, acceleration, and fall time:

$$v = v_0 + at$$

Substitute numerical values and evaluate $|v|$:

$$v = 6\,\text{m/s} - (9.81\,\text{m/s}^2)(3\text{s}) = -23.4\,\text{m/s}$$

and

$$|v| = \boxed{23.4\,\text{m/s}}$$

***79** ••

Picture the Problem In the absence of air resistance, the object's acceleration is constant. Choose a coordinate system in which downward is positive and the origin is at the point of release. In this coordinate system, $a = g$ and $y = 120$ m at the bottom of the fall.

Express the distance fallen in the last second in terms of the object's position at impact and its position 1 s before impact:

$$\Delta y_{\text{last second}} = 120\text{ m} - y_{1\,\text{s before impact}} \quad (1)$$

Using a constant-acceleration equation, relate the object's position upon impact to its initial position, initial velocity, and fall time:

$$y = y_0 + v_0 t + \tfrac{1}{2} g t^2$$

or, because $y_0 = 0$ and $v_0 = 0$,

$$y = \tfrac{1}{2} g t_{\text{fall}}^2$$

Solve for the fall time:

$$t_{\text{fall}} = \sqrt{\frac{2y}{g}}$$

Substitute numerical values and evaluate t_{fall}:

$$t_{\text{fall}} = \sqrt{\frac{2(120\,\text{m})}{9.81\,\text{m/s}^2}} = 4.95\,\text{s}$$

We know that, one second before impact, the object has fallen for 3.95 s. Using the same constant-acceleration equation, calculate the object's position 3.95 s into its fall:

$$y(3.95\text{ s}) = \tfrac{1}{2}(9.81\text{ m/s}^2)(3.95\,\text{s})^2 = 76.4\,\text{m}$$

Substitute in equation (1) to obtain:

$$\Delta y_{\text{last second}} = 120\,\text{m} - 76.4\,\text{m} = \boxed{43.6\,\text{m}}$$

80 ••

Picture the Problem In the absence of air resistance, the acceleration of the object is constant. Choose a coordinate system with the origin at the point of release and downward as the positive direction.

Using a constant-acceleration equation, relate the height to the initial and final velocities and the acceleration; solve for the height:

$$v_{\text{f}}^2 = v_0^2 + 2a\Delta y$$

or, because $v_0 = 0$,

$$h = \frac{v_{\text{f}}^2}{2g} \quad (1)$$

Using the definition of average velocity, find the average velocity of the object during its final second of fall:

$$v_{av} = \frac{v_{f\text{-}1s} + v_f}{2} = \frac{\Delta y}{\Delta t} = \frac{38\,\text{m}}{1\,\text{s}} = 38\,\text{m/s}$$

Express the sum of the final velocity and the velocity 1 s before impact:

$$v_{f\text{-}1s} + v_f = 2(38\,\text{m/s}) = 76\,\text{m/s}$$

From the definition of acceleration, we know that the change in velocity of the object, during 1 s of fall, is 9.81 m/s:

$$\Delta v = v_f - v_{f\text{-}1s} = 9.81\ \text{m/s}$$

Add the equations that express the sum and difference of $v_{f-1\,s}$ and v_f and solve for v_f:

$$v_f = \frac{76\,\text{m/s} + 9.81\,\text{m/s}}{2} = 42.9\,\text{m/s}$$

Substitute in equation (1) and evaluate h:

$$h = \frac{(42.9\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)} = \boxed{93.8\,\text{m}}$$

***81** •

Picture the Problem In the absence of air resistance, the acceleration of the stone is constant. Choose a coordinate system with the origin at the bottom of the trajectory and the upward direction positive. Let $v_{f\text{-}1/2}$ be the speed one-half second before impact and v_f the speed at impact.

Using a constant-acceleration equation, express the final speed of the stone in terms of its initial speed, acceleration, and displacement:

$$v_f^2 = v_0^2 + 2a\Delta y$$

Solve for the initial speed of the stone:

$$v_0 = \sqrt{v_f^2 + 2g\Delta y} \qquad (1)$$

Find the average speed in the last half second:

$$v_{av} = \frac{v_{f\text{-}1/2} + v_f}{2} = \frac{\Delta x_{\text{last half second}}}{\Delta t} = \frac{45\,\text{m}}{0.5\,\text{s}}$$

$$= 90\,\text{m/s}$$

and

$$v_{f\text{-}1/2} + v_f = 2(90\,\text{m/s}) = 180\,\text{m/s}$$

Using a constant-acceleration equation, express the change in speed of the stone in the last half second in terms of the acceleration and the elapsed time; solve for the change in its speed:

$$\Delta v = v_f - v_{f\text{-}1/2} = g\Delta t$$

$$= (9.81\,\text{m/s}^2)(0.5\,\text{s})$$

$$= 4.91\,\text{m/s}$$

Add the equations that express the sum and difference of $v_{f-½}$ and v_f and solve for v_f:

$$v_f = \frac{180\,\text{m/s} + 4.91\,\text{m/s}}{2} = 92.5\,\text{m/s}$$

Substitute in equation (1) and evaluate v_0:

$$v_0 = \sqrt{(92.5\text{m/s})^2 + 2(9.81\text{m/s}^2)(-200\text{m})} = \boxed{68.1\,\text{m/s}}$$

Remarks: The stone may be thrown either up or down from the cliff and the results after it passes the cliff on the way down are the same.

82 ••

Picture the Problem In the absence of air resistance, the acceleration of the object is constant. Choose a coordinate system in which downward is the positive direction and the object starts from rest. Apply constant-acceleration equations to find the average velocity of the object during its descent.

Express the average velocity of the falling object in terms of its initial and final velocities:

$$v_{av} = \frac{v_0 + v_f}{2}$$

Using a constant-acceleration equation, express the displacement of the object during the 1st second in terms of its acceleration and the elapsed time:

$$\Delta y_{1\text{st second}} = \frac{gt^2}{2} = 4.91\,\text{m} = 0.4\,h$$

Solve for the displacement to obtain:

$h = 12.3$ m

Using a constant-acceleration equation, express the final velocity of the object in terms of its initial velocity, acceleration, and displacement:

$$v_f^2 = v_0^2 + 2g\Delta y$$

or, because $v_0 = 0$,

$$v_f = \sqrt{2g\Delta y}$$

Substitute numerical values and evaluate the final velocity of the object:

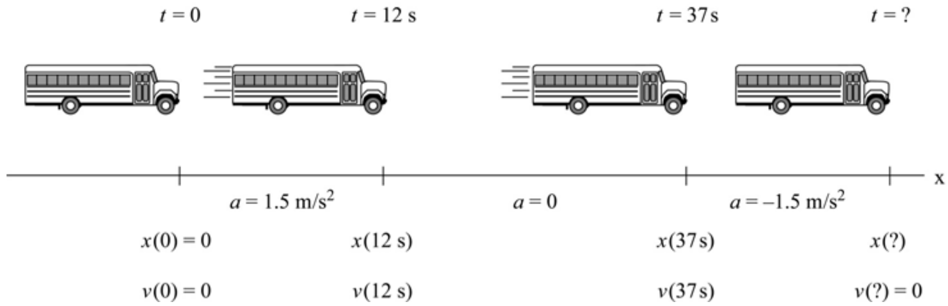
$$v_f = \sqrt{2(9.81\,\text{m/s}^2)(12.3\,\text{m})} = 15.5\,\text{m/s}$$

Substitute in the equation for the average velocity to obtain:

$$v_{av} = \frac{0 + 15.5\,\text{m/s}}{2} = \boxed{7.77\,\text{m/s}}$$

83 ••

Picture the Problem This is a three-part constant-acceleration problem. The bus starts from rest and accelerates for a given period of time, and then it travels at a constant velocity for another period of time, and, finally, decelerates uniformly to a stop. The pictorial representation will help us organize the information in the problem and develop our solution strategy.



(*a*) Express the total displacement of the bus during the three intervals of time.

$$\Delta x_{\text{total}} = \Delta x(0 \to 12\,\text{s}) + \Delta x(12\,\text{s} \to 37\,\text{s}) + \Delta x(37\,\text{s} \to \text{end})$$

Using a constant-acceleration equation, express the displacement of the bus during its first 12 s of motion in terms of its initial velocity, acceleration, and the elapsed time; solve for its displacement:

$$\Delta x(0 \to 12\,\text{s}) = v_0 t + \tfrac{1}{2}at^2$$

or, because $v_0 = 0$,

$$\Delta x(0 \to 12\,\text{s}) = \tfrac{1}{2}at^2 = 108\,\text{m}$$

Using a constant-acceleration equation, express the velocity of the bus after 12 seconds in terms of its initial velocity, acceleration, and the elapsed time; solve for its velocity at the end of 12 s:

$$v_{12\,\text{s}} = v_0 + a_{0\to 12\,\text{s}}\Delta t = (1.5\,\text{m/s}^2)(12\,\text{s}) = 18\,\text{m/s}$$

During the next 25 s, the bus moves with a constant velocity. Using the definition of average velocity, express the displacement of the bus during this interval in terms of its average (constant) velocity and the elapsed time:

$$\Delta x(12\,\text{s} \to 37\,\text{s}) = v_{12\,\text{s}}\Delta t = (18\,\text{m/s})(25\,\text{s}) = 450\,\text{m}$$

Because the bus slows down at the same rate that its velocity increased during the first 12 s of motion, we can conclude that its displacement during this braking period is the same as during its acceleration period and the time to brake to a stop is equal to the time that was required for the bus to accelerate to its cruising speed of 18 m/s. Hence:

$$\Delta x(37\,\text{s} \to 49\text{s}) = 108\,\text{m}$$

Add the displacements to find the distance the bus traveled:

$$\Delta x_{\text{total}} = 108\,\text{m} + 450\,\text{m} + 108\,\text{m} = \boxed{666\,\text{m}}$$

(*b*) Use the definition of average velocity to calculate the average velocity of the bus during this trip:

$$v_{av}=\frac{\Delta x_{total}}{\Delta t}=\frac{666\,\text{m}}{49\,\text{s}}=\boxed{13.6\,\text{m/s}}$$

Remarks: One can also solve this problem graphically. Recall that the area under a velocity as a function-of-time graph equals the displacement of the moving object.

***84** ••

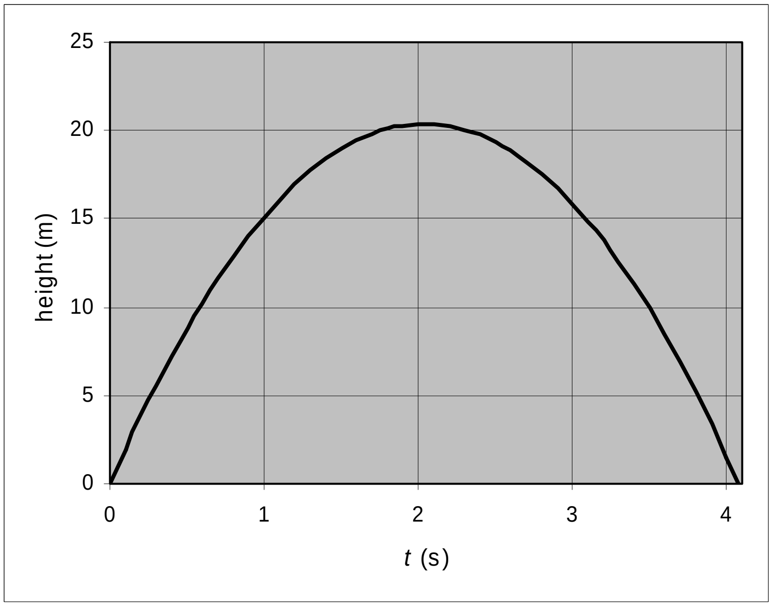
Picture the Problem While we can solve this problem analytically, there are many physical situations in which it is not easy to do so and one has to rely on numerical methods; for example, see the spreadsheet solution shown below. Because we're neglecting the height of the release point, the position of the ball as a function of time is given by $y=v_0t-\frac{1}{2}gt^2$. The formulas used to calculate the quantities in the columns are as follows:

Cell	Content/Formula	Algebraic Form
B1	20	v_0
B2	9.81	g
B5	0	t
B6	B5 + 0.1	$t+\Delta t$
C6	$B$1*B6 – 0.5*$B$2*B6^2	$v_0t-\frac{1}{2}gt^2$

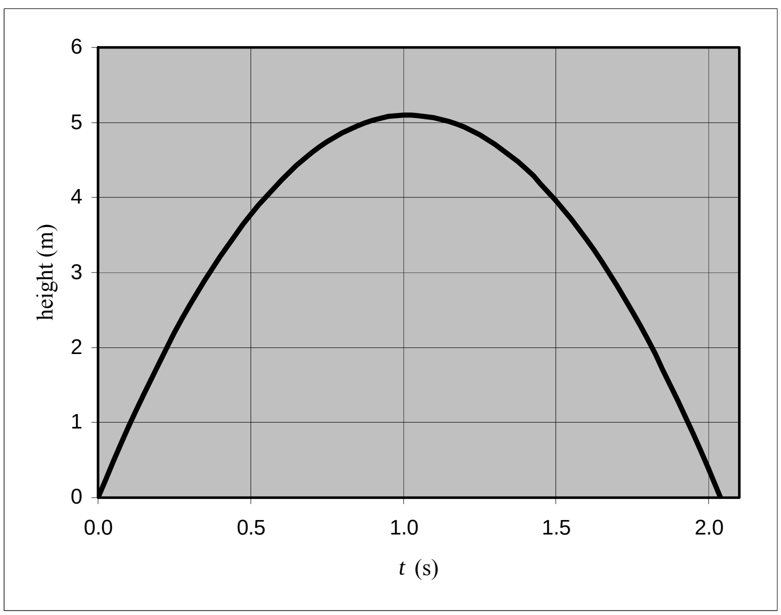
(*a*)

	A	B	C
1	v0 =	20	m/s
2	g =	9.81	m/s^2
3		t	height
4		(s)	(m)
5		0.0	0.00
6		0.1	1.95
7		0.2	3.80
44		3.9	3.39
45		4.0	1.52
46		4.1	–0.45

The graph shown below was generated from the data in the previous table. Note that the maximum height reached is a little more than 20 m and the time of flight is about 4 s.



(b) In the spreadsheet, change the value in cell B1 from 20 to 10. The graph should automatically update. With an initial velocity of 10 m/s, the maximum height achieved is approximately 5 m and the time-of-flight is approximately 2 s.



***85 ••**

Picture the Problem Because the accelerations of both Al and Bert are constant, constant-acceleration equations can be used to describe their motions. Choose the origin of the coordinate system to be where Al decides to begin his sprint.

(a) Using a constant-acceleration equation, relate Al's initial velocity, his acceleration, and the time to reach the end of the trail to his

$$\Delta x = v_0 t + \tfrac{1}{2}at^2$$

displacement in reaching the end of the trail:

Substitute numerical values to obtain:

$$35\,\text{m} = (0.75\,\text{m/s})t + \tfrac{1}{2}(0.5\,\text{m/s}^2)t^2$$

Solve for the time required for Al to reach the end of the trail:

$$t = \boxed{10.4\,\text{s}}$$

(*b*) Using constant-acceleration equations, express the positions of Bert and Al as functions of time. At the instant Al turns around at the end of the trail, $t = 0$. Also, $x = 0$ at a point 35 m from the end of the trail:

$$x_{\text{Bert}} = x_{\text{Bert,0}} + (0.75\,\text{m/s})t$$

and

$$x_{\text{Al}} = x_{\text{Al,0}} - (0.85\,\text{m/s})t = 35\,\text{m} - (0.85\,\text{m/s})t$$

Calculate Bert's position at $t = 0$. At that time he has been running for 10.4 s:

$$x_{\text{Bert,0}} = (0.75\,\text{m/s})(10.4\,\text{s}) = 7.80\,\text{m}$$

Because Bert and Al will be at the same location when they meet, equate their position functions and solve for *t*:

$$7.80\,\text{m} + (0.75\,\text{m/s})t = 35\,\text{m} - (0.85\,\text{m/s})t$$

and

$$t = 17.0\text{ s}$$

To determine the elapsed time from when Al began his accelerated run, we need to add 10.4 s to this time:

$$t_{\text{start}} = 17.0\,\text{s} + 10.4\,\text{s} = \boxed{27.4\,\text{s}}$$

(*c*) Express Bert's distance from the end of the trail when he and Al meet:

$$d_{\text{end of trail}} = 35\,\text{m} - x_{\text{Bert,0}} - d_{\text{Bert runs until he meets Al}}$$

Substitute numerical values and evaluate $d_{\text{end of trail}}$:

$$d_{\text{end of trail}} = 35\,\text{m} - 7.80\,\text{m} - (17\,\text{s})(0.75\,\text{m/s}) = \boxed{14.5\,\text{m}}$$

86 ••

Picture the Problem Generate two curves on one graph with the first curve representing Al's position as a function of time and the second curve representing Bert's position as a function of time. Al's position, as he runs toward the end of the trail, is given by $x_{\text{Al}} = v_0 t + \frac{1}{2}a_{\text{Al}}t^2$ and Bert's position by $x_{\text{Bert}} = x_{0,\text{Bert}} + v_{\text{Bert}}t$. Al's position, once he's reached the end of the trail and is running back toward Bert, is given by $x_{\text{Al}} = x_{\text{Al,0}} + v_{\text{Al}}(t - 10.5\,\text{s})$. The coordinates of the intersection of the two curves give the time and place where they meet. A spreadsheet solution is shown below. The formulas used to calculate the quantities in the columns are as follows:

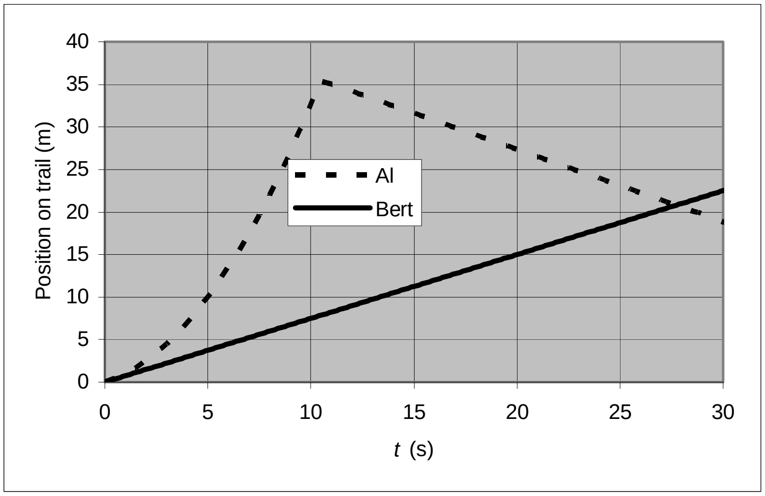
Cell	Content/Formula	Algebraic Form

B1	0.75	v_0
B2	0.50	a_{Al}
B3	–0.85	t
B10	B9 + 0.25	$t + \Delta t$
C10	$B$1*B10 + 0.5*$B$2*B10^2	$v_0 t + \frac{1}{2} a_{Al} t^2$
C52	$C$51 + $B$3*(B52 – $B$51)	$x_{Al,0} + v_{Al}(t - 10.5\,\mathrm{s})$
F10	$F$9 + $B$1*B10	$x_{0,\mathrm{Bert}} + v_{\mathrm{Bert}} t$

(*b*) and (*c*)

	A	B	C	D	E	F
1	v0 =	0.75	m/s			
2	a(Al) =	0.5	m/s^2			
3	v(Al) =	–0.85	m/s			
4						
5		t (s)	x (m)			x (m)
6						
7						
8			Al			Bert
9		0.00	0.00			0.00
10		0.25	0.20			0.19
11		0.50	0.44			0.38
49		10.00	32.50			7.50
50		10.25	33.95			7.69
51		10.50	35.44	*Al reaches		7.88
52		10.75	35.23	end of trail		8.06
53		11.00	35.01	and starts		8.25
54		11.25	34.80	back toward		8.44
55		11.50	34.59	Bert		8.63
56		11.75	34.38			8.81
119		27.50	20.99			20.63
120		27.75	20.78			20.81
121		28.00	20.56			21.00
122		28.25	20.35			21.19
127		29.50	19.29			22.13
128		29.75	19.08			22.31
129		30.00	18.86			22.50

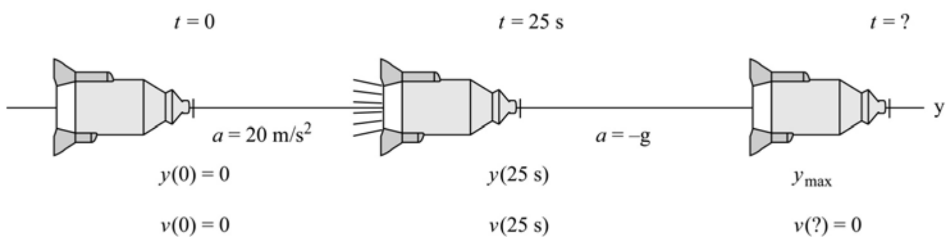
The graph shown below was generated from the spreadsheet; the positions of both Al and Bert were calculated as functions of time. The dashed curve shows Al's position as a function of time for the two parts of his motion. The solid line that is linear from the origin shows Bert's position as a function of time.



Note that the spreadsheet and the graph (constructed from the spreadsheet data) confirm the results in Problem 85 by showing Al and Bert meeting at about 14.5 m from the end of the trail after an elapsed time of approximately 28 s.

87 ••

Picture the Problem This is a two-part constant-acceleration problem. Choose a coordinate system in which the upward direction is positive. The pictorial representation will help us organize the information in the problem and develop our solution strategy.



(*a*) Express the highest point the rocket reaches, *h*, as the sum of its displacements during the first two stages of its flight:

$$h = \Delta x_{\text{1st stage}} + \Delta x_{\text{2nd stage}}$$

Using a constant-acceleration equation, express the altitude reached in the first stage in terms of the rocket's initial velocity, acceleration, and burn time; solve for the first stage altitude:

$$\begin{aligned} x_{\text{1st stage}} &= x_0 + v_0 t + \tfrac{1}{2} a_{\text{1st stage}} t^2 \\ &= \tfrac{1}{2}(20\ \text{m/s}^2)(25\ \text{s})^2 \\ &= 6250\ \text{m} \end{aligned}$$

Using a constant-acceleration equation, express the velocity of the rocket at the end of its first stage in terms of its initial velocity, acceleration, and displacement; calculate its end-of-first-stage velocity:

$$\begin{aligned} v_{\text{1st stage}} &= v_0 + a_{\text{1st stage}} t \\ &= (20\ \text{m/s}^2)(25\ \text{s}) \\ &= 500\ \text{m/s} \end{aligned}$$

Using a constant-acceleration equation, express the final velocity of the rocket during the remainder of its climb in terms of its shut-off velocity, free-fall acceleration, and displacement; solve for its displacement:

$$v_{\text{highest point}}^2 = v_{\text{shutoff}}^2 + 2a_{\text{2nd stage}}\Delta y_{\text{2nd stage}}$$

and, because $v_{\text{highest point}} = 0$,

$$\Delta y_{\text{2nd stage}} = \frac{-v_{\text{shutoff}}^2}{-2g} = \frac{(500\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)} = 1.2742\times10^4\ \text{m}$$

Substitute in the expression for the total height to obtain:

$$h = 6250\,\text{m} + 1.27\times10^4\ \text{m} = \boxed{19.0\,\text{km}}$$

(*b*) Express the total time the rocket is in the air in terms of the three segments of its flight:

$$\Delta t_{\text{total}} = \Delta t_{\text{powered climb}} + \Delta t_{\text{2nd segment}} + \Delta t_{\text{descent}} = 25\,\text{s} + \Delta t_{\text{2nd segment}} + \Delta t_{\text{descent}}$$

Express $\Delta t_{\text{2nd segment}}$ in terms of the rocket's displacement and average velocity:

$$\Delta t_{\text{2nd segment}} = \frac{\text{Displacement}}{\text{Average velocity}}$$

Substitute numerical values and evaluate $\Delta t_{\text{2nd segment}}$:

$$\Delta t_{\text{2nd segment}} = \frac{1.2742\times10^4\ \text{m}}{\left(\dfrac{0+500\,\text{m/s}}{2}\right)} = 50.97\ \text{s}$$

Using a constant-acceleration equation, relate the fall distance to the descent time:

$$\Delta y = v_0 t + \tfrac{1}{2}g(\Delta t_{\text{descent}})^2$$

or, because $v_0 = 0$,

$$\Delta y = \tfrac{1}{2}g(\Delta t_{\text{descent}})^2$$

Solve for $\Delta t_{\text{descent}}$:

$$\Delta t_{\text{descent}} = \sqrt{\frac{2\Delta y}{g}}$$

Substitute numerical values and evaluate $\Delta t_{\text{descent}}$:

$$\Delta t_{\text{descent}} = \sqrt{\frac{2(1.90\times10^4\ \text{m})}{9.81\,\text{m/s}^2}} = 62.2\,\text{s}$$

Substitute and calculate the total time the rocket is in the air:

$$\Delta t = 25\,\text{s} + 50.97\,\text{s} + 62.2\,\text{s} = 138\,\text{s} = \boxed{2\,\text{min}\ 18\,\text{s}}$$

(*c*) Using a constant-acceleration equation, express the impact velocity of the rocket in terms of its initial downward velocity, acceleration under free-fall, and time of descent; solve for its impact velocity:

$$v_{\text{impact}} = v_0 + g\Delta t_{\text{descent}}$$

and, because $v_0 = 0$,

$$v_{\text{impact}} = g\Delta t = (9.81\,\text{m/s}^2)(62.2\,\text{s}) = \boxed{610\,\text{m/s}}$$

88 ••

Picture the Problem In the absence of air resistance, the acceleration of the flowerpot is constant. Choose a coordinate system in which downward is positive and the origin is at the point from which the flowerpot fell. Let t = time when the pot is at the top of the window, and $t + \Delta t$ the time when the pot is at the bottom of the window. To find the distance from the ledge to the top of the window, first find the time t_{top} that it takes the pot to fall to the top of the window.

Using a constant-acceleration equation, express the distance y below the ledge from which the pot fell as a function of time:

$$y = y_0 + v_0 t + \tfrac{1}{2}at^2$$

Since $a = g$ and $v_0 = y_0 = 0$,

$$y = \tfrac{1}{2}gt^2$$

Express the position of the pot as it reaches the top of the window:

$$y_{top} = \tfrac{1}{2}gt_{top}^2$$

Express the position of the pot as it reaches the bottom of the window:

$$y_{bottom} = \tfrac{1}{2}g\left(t_{top} + \Delta t_{window}\right)^2$$

where $\Delta t_{window} = t_{top} - t_{bottom}$

Subtract y_{bottom} from y_{top} to obtain an expression for the displacement Δy_{window} of the pot as it passes the window:

$$\Delta y_{window} = \tfrac{1}{2}g\left[\left(t_{top} + \Delta t_{window}\right)^2 - t_{top}^2\right] = \tfrac{1}{2}g\left[2t_{top}\Delta t_{window} + \left(\Delta t_{window}\right)^2\right]$$

Solve for t_{top}:

$$t_{top} = \frac{\dfrac{2\Delta y_{window}}{g} - \left(\Delta t_{window}\right)^2}{2\Delta t_{window}}$$

Substitute numerical values and evaluate t_{top}:

$$t_{top} = \frac{\dfrac{2(4\,\text{m})}{9.81\,\text{m/s}^2} - (0.2\,\text{s})^2}{2(0.2\,\text{s})} = 1.839\,\text{s}$$

Substitute this value for t_{top} to obtain the distance from the ledge to the top of the window:

$$y_{top} = \tfrac{1}{2}(9.81\,\text{m/s}^2)(1.939\,\text{s})^2 = \boxed{18.4\,\text{m}}$$

***89 ••**

Picture the Problem The acceleration of the glider on the air track is constant. Its average acceleration is equal to the instantaneous (constant) acceleration. Choose a coordinate system in which the initial direction of the glider's motion is the positive direction.

Using the definition of acceleration, express the average acceleration of the glider in terms of the glider's velocity change and the elapsed time:

$$a = a_{av} = \frac{\Delta v}{\Delta t}$$

Using a constant-acceleration equation, express the average velocity of the glider in terms of the displacement of the glider and the elapsed time:

$$v_{av} = \frac{\Delta x}{\Delta t} = \frac{v_0 + v}{2}$$

Solve for and evaluate the initial velocity:

$$v_0 = \frac{2\Delta x}{\Delta t} - v = \frac{2(100\,\text{cm})}{8\,\text{s}} - (-15\,\text{cm/s})$$
$$= \boxed{40.0\,\text{cm/s}}$$

Substitute this value of v_0 and evaluate the average acceleration of the glider:

$$a = \frac{-15\,\text{cm/s} - (40\,\text{cm/s})}{8\,\text{s}}$$
$$= \boxed{-6.88\,\text{cm/s}^2}$$

90 ••

Picture the Problem In the absence of air resistance, the acceleration of the rock is constant and its motion can be described using the constant-acceleration equations. Choose a coordinate system in which the downward direction is positive and let the height of the cliff, which equals the displacement of the rock, be represented by *h*.

Using a constant-acceleration equation, express the height *h* of the cliff in terms of the initial velocity of the rock, acceleration, and time of fall:

$$\Delta y = v_0 t + \tfrac{1}{2}at^2$$

or, because $v_0 = 0$, $a = g$, and $\Delta y = h$,

$$h = \tfrac{1}{2}gt^2$$

Using this equation, express the displacement of the rock during the

a) first two-thirds of its fall, and

$$\tfrac{2}{3}h = \tfrac{1}{2}gt^2 \qquad (1)$$

b) its complete fall in terms of the time required for it to fall this distance.

$$h = \tfrac{1}{2}g(t + 1\,\text{s})^2 \qquad (2)$$

Substitute equation (2) in equation (1) to obtain a quadratic equation in *t*:

$$t^2 - (4\text{ s})t - 2\text{ s}^2 = 0$$

Solve for the positive root:

$$t = 4.45\,\text{s}$$

Evaluate $\Delta t = t + 1$ s:

$$\Delta t = 4.45\text{ s} + 1\text{ s} = 5.45\text{ s}$$

Substitute numerical values in equation (2) and evaluate *h*:

$$h = \tfrac{1}{2}(9.81\,\text{m/s}^2)(5.45\,\text{s})^2 = \boxed{146\,\text{m}}$$

91 •••

Picture the Problem Assume that the acceleration of the car is constant. The total distance the car travels while stopping is the sum of the distances it travels during the driver's reaction time and the time it travels while braking. Choose a coordinate system in which the positive direction is the direction of motion of the automobile and apply a constant-acceleration equation to obtain a quadratic equation in the car's initial speed v_0.

(*a*) Using a constant-acceleration equation, relate the velocity of the car to its initial velocity, acceleration, and displacement during braking:

$$v^2 = v_0^2 + 2a\Delta x_{\text{brk}}$$

or, because the final velocity is zero,

$$0 = v_0^2 + 2a\Delta x_{\text{brk}}$$

Solve for the distance traveled during braking:

$$\Delta x_{\text{brk}} = -\frac{v_0^2}{2a}$$

Express the total distance traveled by the car as the sum of the distance traveled during the reaction time and the distance traveled while slowing down:

$$\Delta x_{\text{tot}} = \Delta x_{\text{react}} + \Delta x_{\text{brk}} = v_0\Delta t_{\text{react}} - \frac{v_0^2}{2a}$$

Rearrange this quadratic equation to obtain:

$$v_0^2 - 2a\Delta t_{\text{react}}v_0 + 2a\Delta x_{\text{tot}} = 0$$

Substitute numerical values and simplify to obtain:

$$v_0^2 - 2\left(-7\ \text{m/s}^2\right)\left(0.5\ \text{s}\right)v_0 + 2\left(-7\ \text{m/s}^2\right)\left(4\ \text{m}\right) = 0$$

or

$$v_0^2 + \left(7\ \text{m/s}\right)v_0 - 56\ \text{m}^2/\text{s}^2 = 0$$

Solve the quadratic equation for the positive root to obtain:

$$v_0 = 4.7613558\ \text{m/s}$$

Convert this speed to mi/h::

$$v_0 = \left(4.7613558\ \text{m/s}\right)\left(\frac{1\ \text{mi/h}}{0.477\ \text{m/s}}\right) = \boxed{10.7\ \text{mi/h}}$$

(*b*) Find the reaction-time distance:

$$\Delta x_{\text{react}} = v_0\Delta t_{\text{react}} = (4.76\ \text{m/s})(0.5\ \text{s}) = 2.38\ \text{m}$$

Express and evaluate the ratio of the reaction distance to the total distance:

$$\frac{\Delta x_{\text{react}}}{\Delta x_{\text{tot}}} = \frac{2.38\ \text{m}}{4\ \text{m}} = \boxed{0.595}$$

92 ••

Picture the Problem Assume that the accelerations of the trains are constant. Choose a coordinate system in which the direction of the motion of the train on the left is the positive direction. Take $x_o = 0$ as the position of the train on the left at $t = 0$.

Using a constant-acceleration equation, relate the distance the train on the left will travel before the trains pass to its acceleration and the time-to-passing:

$$x_L = \tfrac{1}{2}a_L t^2 = \tfrac{1}{2}\left(1.4\,\text{m/s}^2\right)t^2 = \left(0.7\,\text{m/s}^2\right)t^2$$

Using a constant-acceleration equation, relate the position of the train on the right to its initial velocity, position, and acceleration:

$$x_R = 40\,\text{m} - \tfrac{1}{2}a_R t^2 = 40\,\text{m} - \tfrac{1}{2}\left(2.2\,\text{m/s}^2\right)t^2$$

Equate x_L and x_R and solve for t:

$$0.7t^2 = 40 - 1.1t^2$$

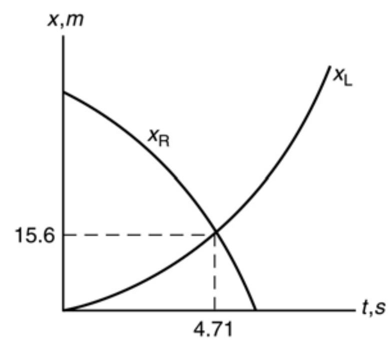
and

$$t = 4.71\,\text{s}$$

Find the position of the train initially on the left, x_L, as they pass:

$$x_L = \tfrac{1}{2}(1.4\,\text{m/s}^2)(4.71\,\text{s})^2 = \boxed{15.6\,\text{m}}$$

Remarks: One can also solve this problem by graphing the functions for x_L and x_R. The coordinates of the intersection of the two curves give one the time-to-passing and the distance traveled by the train on the left.



93 ••

Picture the Problem In the absence of air resistance, the acceleration of the stones is constant. Choose a coordinate system in which the downward direction is positive and the origin is at the point of release of the stones.

Using constant-acceleration equations, relate the positions of the two stones to their initial positions, accelerations, and time-of-fall:

$$x_1 = \tfrac{1}{2}gt^2$$

and

$$x_2 = \tfrac{1}{2}g(t - 1.6\,\text{s})^2$$

Express the difference between x_1 and x_2:

$$x_1 - x_2 = 36\text{ m}$$

Substitute for x_1 and x_2 to obtain:

$$36\,\text{m} = \tfrac{1}{2}gt^2 - \tfrac{1}{2}g\left(t - 1.6\,\text{s}\right)^2$$

Solve this equation for the time t at which the stones will be separated by 36 m:

$t = 3.09$ s

Substitute this result in the expression for x_2 and solve for x_2:

$$x_2 = \tfrac{1}{2}\left(9.81\,\text{m/s}^2\right)\left(3.09\,\text{s} - 1.6\,\text{s}\right)^2 = \boxed{10.9\,\text{m}}$$

***94 ••**

Picture the Problem The acceleration of the police officer's car is positive and constant and the acceleration of the speeder's car is zero. Choose a coordinate system such that the direction of motion of the two vehicles is the positive direction and the origin is at the stop sign.

Express the velocity of the car in terms of the distance it will travel until the police officer catches up to it and the time that will elapse during this chase:

$$v_{\text{car}} = \frac{d_{\text{caught}}}{t_{\text{car}}}$$

Letting t_1 be the time during which she accelerates and t_2 the time of travel at $v_1 = 110$ km/h, express the time of travel of the police officer:

$$t_{\text{officer}} = t_1 + t_2$$

Convert 110 km/h into m/s:

$$v_1 = \left(110\,\text{km/h}\right)(10^3\ \text{m/km})(1\,\text{h}/3600\,\text{s}) = 30.6\,\text{m/s}$$

Express and evaluate t_1:

$$t_1 = \frac{v_1}{a_{\text{motorcycle}}} = \frac{30.6\ \text{m/s}}{6.2\ \text{m/s}^2} = 4.94\,\text{s}$$

Express and evaluate d_1:

$$d_1 = \tfrac{1}{2}v_1 t_1 = \tfrac{1}{2}(30.6\,\text{m/s})(4.94\,\text{s}) = 75.6\,\text{m}$$

Determine d_2:

$$d_2 = d_{\text{caught}} - d_1 = 1400\,\text{m} - 75.6\,\text{m} = 1324.4\,\text{m}$$

Express and evaluate t_2:

$$t_2 = \frac{d_2}{v_1} = \frac{1324.4\,\text{m}}{30.6\,\text{m/s}} = 43.3\,\text{s}$$

Express the time of travel of the car:

$t_{\text{car}} = 2.0$ s + 4.93 s + 43.3 s = 50.2 s

Finally, find the speed of the car:

$$v_{car} = \frac{d_{caught}}{t_{car}} = \frac{1400\text{ m}}{50.2\text{ s}} = 27.9\text{ m/s}$$
$$= (27.9\text{ m/s})\left(\frac{1\text{ mi/h}}{0.447\text{ m/s}}\right)$$
$$= \boxed{62.4\text{ mi/h}}$$

95 ••

Picture the Problem In the absence of air resistance, the acceleration of the stone is constant. Choose a coordinate system in which downward is positive and the origin is at the point of release of the stone and apply constant-acceleration equations.

Using a constant-acceleration equation, express the height of the cliff in terms of the initial position of the stones, acceleration due to gravity, and time for the first stone to hit the water:

$$h = \tfrac{1}{2}gt_1^2$$

Express the displacement of the second stone when it hits the water in terms of its initial velocity, acceleration, and time required for it to hit the water.

$$d_2 = v_{02}t_2 + \tfrac{1}{2}gt_2^2$$
where $t_2 = t_1 - 1.6$ s.

Because the stones will travel the same distances before hitting the water, equate h and d_2 and solve for t.

$$\tfrac{1}{2}gt_1^2 = v_{02}t_2 + \tfrac{1}{2}gt_2^2$$
or
$$\tfrac{1}{2}(9.81\text{m/s}^2)t_1^2 = (32\text{m/s})(t_1 - 1.6\text{s}) + \tfrac{1}{2}(9.81\text{m/s}^2)(t_1 - 1.6\text{s})^2$$

Solve for t_1 to obtain:

$$t_1 = 2.37\text{ s}$$

Substitute for t_1 and evaluate h:

$$h = \tfrac{1}{2}(9.81\text{ m/s}^2)(2.37\text{ s})^2 = \boxed{27.6\text{ m}}$$

96 •••

Picture the Problem Assume that the acceleration of the passenger train is constant. Let $x_p = 0$ be the location of the passenger train engine at the moment of sighting the freight train's end; let $t = 0$ be the instant the passenger train begins to slow (0.4 s after the passenger train engineer sees the freight train ahead). Choose a coordinate system in which the direction of motion of the trains is the positive direction and use constant-acceleration equations to express the positions of the trains in terms of their initial positions, speeds, accelerations, and elapsed time.

(*a*) Using constant-acceleration equations, write expressions for the positions of the front of the passenger train and the rear of the

$$x_p = (29\text{ m/s})(t + 0.4\text{ s}) - \tfrac{1}{2}at^2$$
$$x_f = (360\text{ m}) + (6\text{ m/s})(t + 0.4\text{ s})$$
where x_p and x_f are in meters if t is in

freight train, x_p and x_f, respectively: seconds.

Equate $x_f = x_p$ to obtain an equation for t:

$$\tfrac{1}{2}at^2 - (23\,\text{m/s})t + 350.8\,\text{m} = 0$$

Find the discriminant $(D = \text{B}^2 - 4\text{AC})$ of this equation:

$$D = (23\,\text{m/s})^2 - 4\left(\frac{a}{2}\right)(350.8\,\text{m})$$

The equation must have real roots if it is to describe a collision. The necessary condition for real roots is that the discriminant be greater than or equal to zero:

If $(23\text{ m/s})^2 - a\,(701.6\text{ m}) \geq 0$, then

$$a \leq \boxed{0.754\,\text{m/s}^2}$$

(b) Express the relative speed of the trains:

$$v_{\text{rel}} = v_{\text{pf}} = v_{\text{p}} - v_{\text{f}} \qquad (1)$$

Repeat the previous steps with $a = 0.754\text{ m/s}^2$ and a 0.8 s reaction time. The quadratic equation that guarantees real roots with the longer reaction time is:

$$\tfrac{1}{2}(0.754\,\text{m/s}^2)t^2 - (23\,\text{m/s})t + 341.6\,\text{m} = 0$$

Solve for t to obtain the collision times:

$t = 25.6$ s and $t = 35.4$ s

Note that at $t = 35.4$ s, the trains have already collided; therefore this root is not a meaningful solution to our problem.

Note: In the graph shown below, you will see why we keep only the smaller of the two solutions.

Now we can substitute our value for t in the constant-acceleration equation for the passenger train and solve for the distance the train has moved prior to the collision:

$$x_p = (29\text{ m/s})(25.6\text{ s} + 0.8\text{ s}) - (0.377\text{ m/s}^2)(25.6\text{ s})^2 = 518\,\text{m}$$

Find the speeds of the two trains:

$$v_p = v_{op} + at = (29\text{ m/s}) + (-0.754\text{ m/s}^2)(25.5\text{ s}) = 9.77\text{ m/s}$$

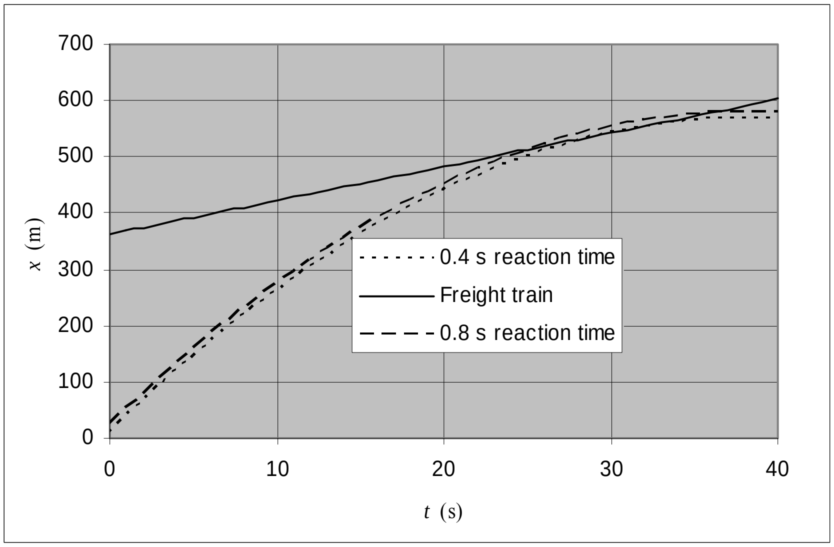
and

$$v_f = v_{of} = 6\text{ m/s}$$

Substitute in equation (1) and evaluate the relative speed of the trains:

$$v_{\text{rel}} = 9.77\,\text{m/s} - 6.00\,\text{m/s} = \boxed{3.77\,\text{m/s}}$$

The graph shows the location of both trains as functions of time. The solid straight line is for the constant velocity freight train; the dashed curves are for the passenger train, with reaction times of 0.4 s for the lower curve and 0.8 s for the upper curve.



Remarks: A collision occurs the first time the curve for the passenger train crosses the curve for the freight train. The smaller of two solutions will always give the time of the collision.

97 •

Picture the Problem In the absence of air resistance, the acceleration of an object near the surface of the earth is constant. Choose a coordinate system in which the upward direction is positive and the origin is at the surface of the earth and apply constant-acceleration equations.

Using a constant-acceleration equation, relate the velocity to the acceleration and displacement:

$$v^2 = v_0^2 + 2a\Delta y$$

or, because $v = 0$ and $a = -g$,

$$0 = v_0^2 - 2g\Delta y$$

Solve for the height to which the projectile will rise:

$$h = \Delta y = \frac{v_0^2}{2g}$$

Substitute numerical values and evaluate *h*:

$$h = \frac{(300\,\text{m/s})^2}{2(9.81\text{ m/s}^2)} = \boxed{4.59\,\text{km}}$$

***98** •

Picture the Problem This is a composite of two constant accelerations with the acceleration equal to one constant prior to the elevator hitting the roof, and equal to a different constant after crashing through it. Choose a coordinate system in which the upward direction is positive and apply constant-acceleration equations.

(*a*) Using a constant-acceleration equation, relate the velocity to the acceleration and displacement:

$$v^2 = v_0^2 + 2\,a\,\Delta y$$

or, because $v = 0$ and $a = -g$,

$$0 = v_0^2 - 2\,g\,\Delta y$$

Solve for v_0:

$$v_0 = \sqrt{2g\Delta y}$$

Substitute numerical values and evaluate v_0:

$$v_0 = \sqrt{2(9.81\,\text{m/s}^2)(10^4\,\text{m})} = \boxed{443\,\text{m/s}}$$

(*b*) Find the velocity of the elevator just before it crashed through the roof:

$$v_f = 2 \times 443\ \text{m/s} = 886\ \text{m/s}$$

Using the same constant-acceleration equation, this time with $v_0 = 0$, solve for the acceleration:

$$v^2 = 2a\Delta y$$

Substitute numerical values and evaluate a:

$$a = \frac{(886\,\text{m/s})^2}{2(150\,\text{m})} = 2.62\times 10^3\ \text{m/s}^2$$
$$= \boxed{267g}$$

99 ••

Picture the Problem Choose a coordinate system in which the upward direction is positive. We can use a constant-acceleration equation to find the beetle's velocity as its feet lose contact with the ground and then use this velocity to calculate the height of its jump.

Using a constant-acceleration equation, relate the beetle's maximum height to its launch velocity, velocity at the top of its trajectory, and acceleration once it is airborne; solve for its maximum height:

$$v_{\text{highest point}}^2 = v_{\text{launch}}^2 + 2a\Delta y_{\text{free fall}}$$
$$= v_{\text{launch}}^2 + 2(-g)h$$

Because $v_{\text{highest point}} = 0$:

$$h = \frac{v_{\text{launch}}^2}{2g}$$

Now, in order to determine the beetle's launch velocity, relate its time of contact with the ground to its acceleration and push-off distance:

$$v_{\text{launch}}^2 = v_0^2 + 2a\Delta y_{\text{launch}}$$

or, because $v_0 = 0$,

$$v_{\text{launch}}^2 = 2a\Delta y_{\text{launch}}$$

Substitute numerical values and evaluate v_{launch}^2:

$$v_{\text{launch}}^2 = 2(400)(9.81\,\text{m/s}^2)(0.6\times 10^{-2}\,\text{m})$$
$$= 47.1\,\text{m}^2/\text{s}^2$$

Substitute to find the height to which the beetle can jump:

$$h = \frac{v_{\text{launch}}^2}{2g} = \frac{47.1\,\text{m}^2/\text{s}^2}{2(9.81\,\text{m/s}^2)} = \boxed{2.40\,\text{m}}$$

Using a constant-acceleration equation, relate the velocity of the beetle at its maximum height to its launch velocity, free-fall acceleration while in the air, and time-to-maximum height:

$$v = v_0 + at$$

or

$$v_{\text{max. height}} = v_{\text{launch}} - gt_{\text{max. height}}$$

and, because $v_{\text{max height}} = 0$,

$$0 = v_{\text{launch}} - gt_{\text{max. height}}$$

Solve for $t_{\text{max height}}$:

$$t_{\text{max height}} = \frac{v_{\text{launch}}}{g}$$

For zero displacement and constant acceleration, the time-of-flight is twice the time-to-maximum height:

$$t_{\text{flight}} = 2t_{\text{max. height}} = \frac{2v_{\text{launch}}}{g}$$

$$= \frac{2(6.86\,\text{m/s})}{9.81\,\text{m/s}^2} = \boxed{1.40\,\text{s}}$$

100 •

Picture the Problem Because its acceleration is constant we can use the constant-acceleration equations to describe the motion of the automobile.

Using a constant-acceleration equation, relate the velocity to the acceleration and displacement:

$$v^2 = v_0^2 + 2a\Delta x$$

or, because $v = 0$,

$$0 = v_0^2 + 2a\Delta x$$

Solve for the acceleration *a:*

$$a = \frac{-v_0^2}{2\Delta x}$$

Substitute numerical values and evaluate *a*:

$$a = \frac{-\left[(98\,\text{km/h})(10^3\,\text{m/km})(1\,\text{h}/3600\,\text{s})\right]^2}{2(50\text{m})}$$

$$= \boxed{-7.41\,\text{m/s}^2}$$

Express the ratio of *a* to *g* and then solve for *a*:

$$\frac{a}{g} = \frac{-7.41\,\text{m/s}^2}{9.81\,\text{m/s}^2} = -0.755$$

and $a = \boxed{-0.755g}$

Using the definition of average acceleration, solve for the stopping time:

$$a_{\text{av}} = \frac{\Delta v}{\Delta t} \Rightarrow \Delta t = \frac{\Delta v}{a_{\text{av}}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{(-98\,\text{km/h})(10^3\,\text{m/km})(1\,\text{h}/3600\,\text{s})}{-7.41\,\text{m/s}^2}$$

$$= \boxed{3.67\,\text{s}}$$

***101 ••**

Picture the Problem In the absence of air resistance, the puck experiences constant acceleration and we can use constant-acceleration equations to describe its position as a function of time. Choose a coordinate system in which downward is positive, the particle starts from rest ($v_o = 0$), and the starting height is zero ($y_0 = 0$).

Using a constant-acceleration equation, relate the position of the falling puck to the acceleration and the time. Evaluate the y-position at successive equal time intervals Δt, $2\Delta t$, $3\Delta t$, etc:

$$y_1 = \frac{-g}{2}(\Delta t)^2 = \frac{-g}{2}(\Delta t)^2$$

$$y_2 = \frac{-g}{2}(2\Delta t)^2 = \frac{-g}{2}(4)(\Delta t)^2$$

$$y_3 = \frac{-g}{2}(3\Delta t)^2 = \frac{-g}{2}(9)(\Delta t)^2$$

$$y_4 = \frac{-g}{2}(4\Delta t)^2 = \frac{-g}{2}(16)(\Delta t)^2$$

etc.

Evaluate the changes in those positions in each time interval:

$$\Delta y_{10} = y_1 - 0 = \left(\frac{-g}{2}\right)(\Delta t)^2$$

$$\Delta y_{21} = y_2 - y_1 = 3\left(\frac{-g}{2}\right)(\Delta t)^2 = 3\Delta y_{10}$$

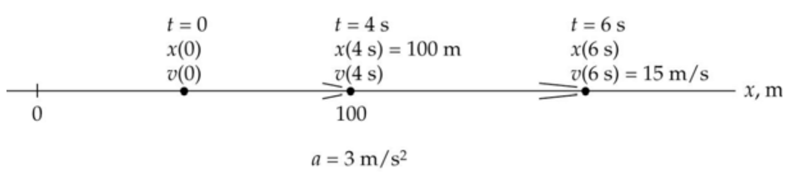
$$\Delta y_{32} = y_3 - y_2 = 5\left(\frac{-g}{2}\right)(\Delta t)^2 = 5\Delta y_{10}$$

$$\Delta y_{43} = y_4 - y_3 = 7\left(\frac{-g}{2}\right)(\Delta t)^2 = 7\Delta y_{10}$$

etc.

102 ••

Picture the Problem Because the particle moves with a constant acceleration we can use the constant-acceleration equations to describe its motion. A pictorial representation will help us organize the information in the problem and develop our solution strategy.



Using a constant-acceleration equation, find the position x at $t = 6$ s. To find x at $t = 6$ s, we first need to find v_0 and x_0:

$$x = x_0 + v_0 t + \tfrac{1}{2}at^2$$

Using the information that when $t = 4$ s, $x = 100$ m, obtain an equation in x_0 and v_0:

$$x(4\,\text{s}) = 100\,\text{m} = x_0 + v_0(4\,\text{s}) + \tfrac{1}{2}(3\,\text{m/s}^2)(4\,\text{s})^2$$

or

$$x_0 + (4\,\text{s})v_0 = 76\,\text{m}$$

Using the information that when $t = 6$ s, $v = 15$ m/s, obtain a second equation in x_0 and v_0:

$$v(6\,\text{s}) = v_0 + (3\,\text{m/s}^2)(6\,\text{s})$$

Solve for v_0 to obtain:

$v_0 = -3$ m/s

Substitute this value for v_0 in the previous equation and solve for x_0:

$x_0 = 88$ m

Substitute for x_0 and v_0 and evaluate x at $t = 6$ s:

$$x(6\,\text{s}) = 88\,\text{m} + (-3\,\text{m/s})\,(6\,\text{s}) + \tfrac{1}{2}(3\,\text{m/s}^2)\,(6\,\text{s})^2 = \boxed{124\,\text{m}}$$

***103 ••**

Picture the Problem We can use constant-acceleration equations with the final velocity $v = 0$ to find the acceleration and stopping time of the plane.

(*a*) Using a constant-acceleration equation, relate the known velocities to the acceleration and displacement:

$$v^2 = v_0^2 + 2a\Delta x$$

Solve for a:

$$a = \frac{v^2 - v_0^2}{2\Delta x} = \frac{-v_0^2}{2\Delta x}$$

Substitute numerical values and evaluate a:

$$a = \frac{-(60\,\text{m/s})^2}{2(70\,\text{m})} = \boxed{-25.7\,\text{m/s}^2}$$

(*b*) Using a constant-acceleration equation, relate the final and initial speeds of the plane to its acceleration and stopping time:

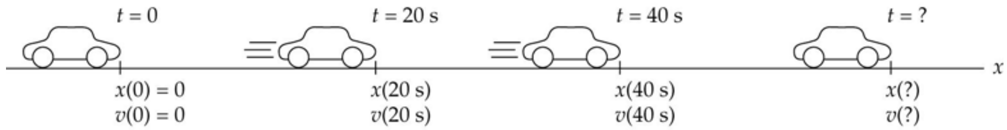
$$v = v_0 + a\Delta t$$

Solve for and evaluate the stopping time:

$$\Delta t = \frac{v - v_0}{a} = \frac{0 - 60\,\text{m/s}}{-25.7\,\text{m/s}^2} = \boxed{2.33\,\text{s}}$$

104 ••

Picture the Problem This is a multipart constant-acceleration problem using three different constant accelerations (+2 m/s^2 for 20 s, then zero for 20 s, and then –3 m/s^2 until the automobile stops). The final velocity is zero. The pictorial representation will help us organize the information in the problem and develop our solution strategy.



Add up all the displacements to get the total:

$$\Delta x_{03} = \Delta x_{01} + \Delta x_{12} + \Delta x_{23}$$

Using constant-acceleration formulas, find the first displacement:

$$\Delta x_{01} = v_0 t_1 + \tfrac{1}{2} a_{01} t_1^2$$
$$= 0 + \tfrac{1}{2}(2\text{ m/s}^2)(20\text{ s})^2 = 400\text{ m}$$

The speed is constant for the second displacement. Find the displacement:

$$\Delta x_{12} = v_1 (t_2 - t_1)$$
where $\mathrm{v}_1 = v_0 + a_{01} t_1 = 0 + a_{01} t_1$ and
$$\Delta x_{12} = a_{01} t_1 (t_2 - t_1)$$
$$= (2\text{ m/s}^2)(20\text{ s})(20\text{ s}) = 800\ \text{ m}$$

Find the displacement during the braking interval:

$$v_3^2 = v_2^2 + 2a_{23}\Delta x_{23}$$
where $v_2 = v_1 = a_{01} t_1$ and $v_3 = 0$ and
$$\Delta x_{23} = \frac{0^2 - (a_{01} t_1)^2}{2a_{23}} = \frac{-[(2\text{ m/s})(20\text{ s})]^2}{2(-3\text{m/s}^2)}$$
$$= 267\text{m}$$

Add the displacements to get the total:

$$\Delta x_{03} = \Delta x_{01} + \Delta x_{12} + \Delta x_{23} = 1467\text{ m}$$
$$= \boxed{1.47\text{ km}}$$

Remarks: Because the area under the curve of a velocity-versus-time graph equals the displacement of the object experiencing the acceleration, we could solve this problem by plotting the velocity as a function of time and finding the area bounded by it and the time axis.

***105** ••

Picture the Problem Note: No material body can travel at speeds faster than light. When one is dealing with problems of this sort, the kinematic formulae for displacement, velocity and acceleration are no longer valid, and one must invoke the special theory of relativity to answer questions such as these. For now, ignore such subtleties. Although the formulas you are using (i.e., the constant- acceleration equations) are not quite correct, your answer to part (*b*) will be wrong by about 1%.

(*a*) This part of the problem is an exercise in the conversion of units. Make use of the fact that 1 c·y = 9.47×10^{15} m and 1 y = 3.16×10^{7} s:

$$g = (9.81\text{m/s}^2)\left(\frac{1c\cdot\text{y}}{9.47\times10^{15}\text{m}}\right)\left(\frac{(3.16\times10^{7}\text{s})^2}{(1\text{ y})^2}\right) = \boxed{1.03c\cdot\text{y}/\text{y}^2}$$

(*b*) Let $t_{1/2}$ represent the time it takes to reach the halfway point. Then the total trip time is:

$$t = 2\,t_{1/2} \qquad (1)$$

Use a constant- acceleration equation to relate the half-distance to Mars Δx to the initial speed, acceleration, and half-trip time $t_{1/2}$:

$$\Delta x = v_0 t + \tfrac{1}{2} a t_{1/2}^2$$

Because $v_0 = 0$ and $a = g$:

$$t_{1/2} = \sqrt{\frac{2\Delta x}{a}}$$

The distance from Earth to Mars at closest approach is 7.8×10^{10} m. Substitute numerical values and evaluate $t_{1/2}$:

$$t_{1/2} = \sqrt{\frac{2\left(3.9\times10^{10}\text{ m}\right)}{9.81\text{m/s}^2}} = 8.92\times10^4\text{ s}$$

Substitute for $t_{1/2}$ in equation (1) to obtain:

$$t = 2\left(8.92\times10^4\text{ s}\right) = 1.78\times10^5\text{ s} \approx \boxed{2\text{d}}$$

Remarks: Our result in part (*b*) seems remarkably short, considering how far Mars is and how low the acceleration is.

106 •

Picture the Problem Because the elevator accelerates uniformly for half the distance and uniformly decelerates for the second half, we can use constant-acceleration equations to describe its motion

Let $t_{1/2} = 40$ s be the time it takes to reach the halfway mark. Use the constant-acceleration equation that relates the acceleration to the known variables to obtain:

$$\Delta y = v_0 t + \tfrac{1}{2} a t^2$$

or, because $v_0 = 0$,

$$\Delta y = \tfrac{1}{2} a t^2$$

Solve for a:

$$a = \frac{2\,\Delta y}{t_{1/2}^2}$$

Substitute numerical values and evaluate a:

$$a = \frac{2\left(\tfrac{1}{2}\right)\left(1173\,\text{ft}\right)\left(1\,\text{m}/3.281\,\text{ft}\right)}{\left(40\,\text{s}\right)^2} = 0.223\,\text{m/s}^2$$

$$= \boxed{0.0228g}$$

107 ••

Picture the Problem Because the acceleration is constant, we can describe the motions of the train using constant-acceleration equations. Find expressions for the distances traveled, separately, by the train and the passenger. When are they equal? Note that the train is accelerating and the passenger runs at a constant minimum velocity (zero acceleration) such that she can just catch the train.

1. Using the subscripts "train" and "p" to refer to the train and the passenger and the subscript "c" to identify "critical" conditions, express the position of the train and the passenger:

$$x_{\text{train,c}}(t_{\text{c}}) = \frac{a_{\text{train}}}{2} t_{\text{c}}^2$$

and

$$x_{\text{p,c}}(t_{\text{c}}) = v_{\text{p,c}}(t_{\text{c}} - \Delta t)$$

Express the critical conditions that must be satisfied if the passenger is to catch the train:

$$v_{\text{train,c}} = v_{\text{p,c}}$$

and

$$x_{\text{train,c}} = x_{\text{p,c}}$$

2. Express the train's average velocity.

$$v_{\text{av}}(0 \text{ to } t_{\text{c}}) = \frac{0 + v_{\text{train,c}}}{2} = \frac{v_{\text{train,c}}}{2}$$

3. Using the definition of average velocity, express v_{av} in terms of $x_{\text{p,c}}$ and t_{c}.

$$v_{\text{av}} \equiv \frac{\Delta x}{\Delta t} = \frac{0 + x_{\text{p,c}}}{0 + t_{\text{c}}} = \frac{x_{\text{p,c}}}{t_{\text{c}}}$$

4. Combine steps 2 and 3 and solve for $x_{\text{p,c}}$.

$$x_{\text{p,c}} = \frac{v_{\text{train,c}} t_{\text{c}}}{2}$$

5. Combine steps 1 and 4 and solve for t_{c}.

$$v_{\text{p,c}}(t_{\text{c}} - \Delta t) = \frac{v_{\text{train,c}} t_{\text{c}}}{2}$$

or

$$t_{\text{c}} - \Delta t = \frac{t_{\text{c}}}{2}$$

and

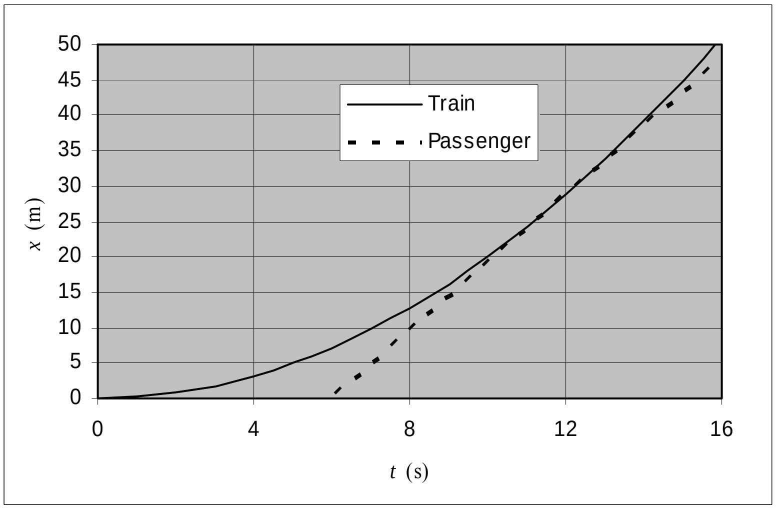
$t_{\text{c}} = 2\,\Delta t = 2\text{ (6 s)} = 12\text{ s}$

6. Finally, combine steps 1 and 5 and solve for $v_{\text{train, c}}$.

$$v_{\text{p,c}} = v_{\text{train,c}} = a_{\text{train}} t_{\text{c}} = (0.4\,\text{m/s}^2)(12\,\text{s})$$

$$= \boxed{4.80\text{ m/s}}$$

The graph shows the location of both the passenger and the train as a function of time. The parabolic solid curve is the graph of $x_{\text{train}}(t)$ for the accelerating train. The straight dashed line is passenger's position $x_{\text{p}}(t)$ if she arrives at $\Delta t = 6.0$ s after the train departs. When the passenger catches the train, our graph shows that her speed and that of the train must be equal ($v_{\text{train,c}} = v_{\text{p,c}}$). Do you see why?



108 •••

Picture the Problem Both balls experience constant acceleration once they are in flight. Choose a coordinate system with the origin at the ground and the upward direction positive. When the balls collide they are at the same height above the ground.

Using constant-acceleration equations, express the positions of both balls as functions of time. At the ground $y = 0$.

$$y_A = h - \tfrac{1}{2}gt^2$$
and
$$y_B = v_0 t - \tfrac{1}{2}gt^2$$

The conditions at collision are that the heights are equal and the velocities are related:

$$y_A = y_B$$
and
$$v_A = -2v_B$$

Express the velocities of both balls as functions of time:

$$v_A = -gt$$
and
$$v_B = v_0 - gt$$

Substituting the position and velocity functions into the conditions at collision gives:

$$h - \tfrac{1}{2}gt_c^2 = v_0 t_c - \tfrac{1}{2}gt_c^2$$
and
$$-gt_c = -2(v_0 - gt_c)$$
where t_c is the time of collision.

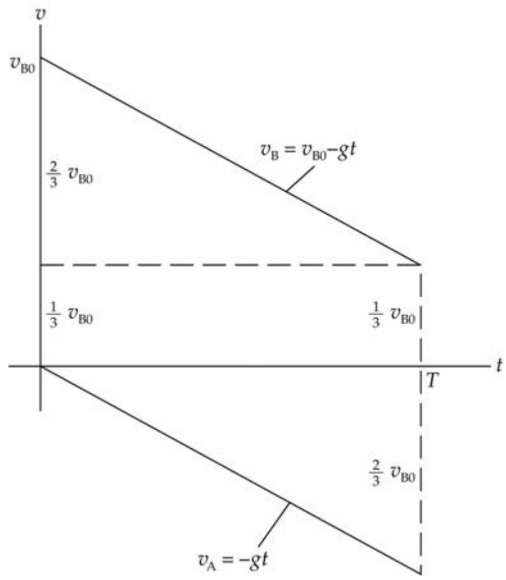
We now have two equations and two unknowns, t_c and v_0. Solving the equations for the unknowns gives:

$$t_c = \sqrt{\frac{2h}{3g}} \text{ and } v_0 = \sqrt{\frac{3gh}{2}}$$

Substitute the expression for t_c into the equation for y_A to obtain the height at collision:

$$y_A = h - \tfrac{1}{2}g\left(\frac{2h}{3g}\right) = \boxed{\frac{2h}{3}}$$

Remarks: We can also solve this problem graphically by plotting velocity- versus-time for both balls. Because ball A starts from rest its velocity is given by $v_A = -gt$. Ball B initially moves with an unknown velocity v_{B0} and its velocity is given by $v_B = v_{B0} - gt$. The graphs of these equations are shown below with T representing the time at which they collide.



The height of the building is the sum of the sum of the distances traveled by the balls. Each of these distances is equal to the magnitude of the area ″under″ the corresponding *v*-versus-*t* curve. Thus, the height of the building equals the area of the parallelogram, which is $v_{B0}T$. The distance that A falls is the area of the lower triangle, which is (1/3) $v_{B0}T$. Therefore, the ratio of the distance fallen by A to the height of the building is 1/3, so the collision takes place at 2/3 the height of the building.

109 •••

Picture the Problem Both balls are moving with constant acceleration. Take the origin of the coordinate system to be at the ground and the upward direction to be positive. When the balls collide they are at the same height above the ground. The velocities at collision are related by $v_A = 4v_B$.

Using constant-acceleration equations, express the positions of both balls as functions of time:

$$y_A = h - \tfrac{1}{2}gt^2$$
and
$$y_B = v_0 t - \tfrac{1}{2}gt^2$$

The conditions at collision are that the heights are equal and the velocities are related:

$$y_A = y_B$$
and
$$v_A = 4v_B$$

Express the velocities of both balls as functions of time:

$$v_A = -gt \text{ and } v_B = v_0 - gt$$

Substitute the position and velocity functions into the conditions at collision to obtain:

$$h - \tfrac{1}{2}gt_c^2 = v_0 t_c - \tfrac{1}{2}gt_c^2$$

and

$$-gt_c = 4(v_0 - gt_c)$$

where t_c is the time of collision.

We now have two equations and two unknowns, t_c and v_0. Solving the equations for the unknowns gives:

$$t_c = \sqrt{\frac{4h}{3g}} \text{ and } v_0 = \sqrt{\frac{3gh}{4}}$$

Substitute the expression for t_c into the equation for y_A to obtain the height at collision:

$$y_A = h - \tfrac{1}{2}g\left(\frac{4h}{3g}\right) = \boxed{\frac{h}{3}}$$

***110 ••**

Determine the Concept The problem describes two intervals of constant acceleration; one when the train's velocity is increasing, and a second when it is decreasing.

(*a*) Using a constant-acceleration equation, relate the half-distance Δx between stations to the initial speed v_0, the acceleration a of the train, and the time-to-midpoint Δt:

$$\Delta x = v_0\Delta t + \tfrac{1}{2}a(\Delta t)^2$$

or, because $v_0 = 0$,

$$\Delta x = \tfrac{1}{2}a(\Delta t)^2$$

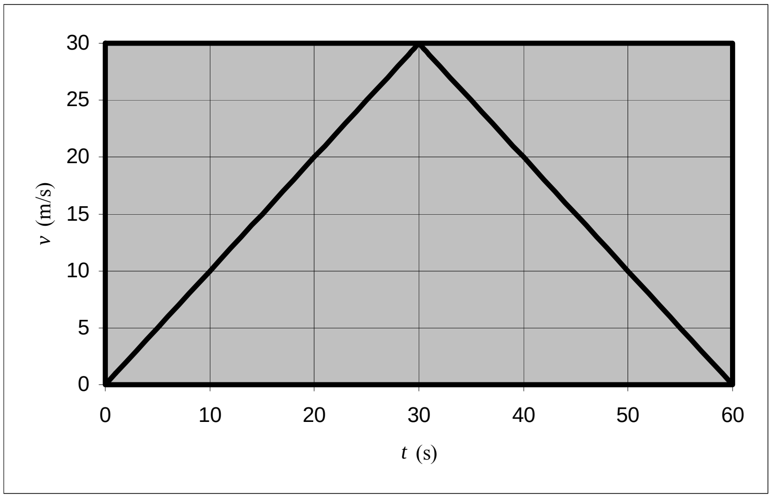
Solve for Δt:

$$\Delta t = \sqrt{\frac{2\Delta x}{a}}$$

Substitute numerical values and evaluate the time-to-midpoint Δt:

$$\Delta t = \sqrt{\frac{2(450\,\text{m})}{1\,\text{m/s}^2}} = 30.0\,\text{s}$$

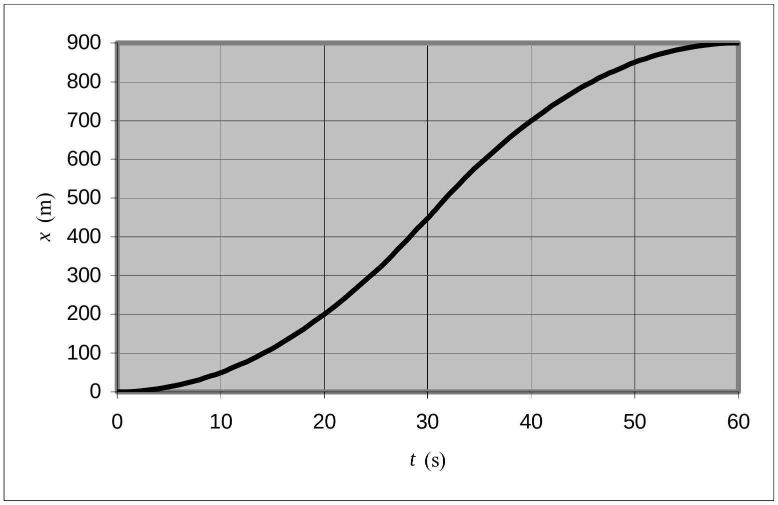
Because the train accelerates uniformly and from rest, the first part of its velocity graph will be linear, pass through the origin, and last for 30 s. Because it slows down uniformly and at the same rate for the second half of its journey, this part of its graph will also be linear but with a negative slope. The graph of v as a function of t is shown below.



(b) The graph of x as a function of t is obtained from the graph of v as a function of t by finding the area under the velocity curve. Looking at the velocity graph, note that when the train has been in motion for 10 s, it will have traveled a distance of

$$\tfrac{1}{2}(10\,\text{s})(10\,\text{m/s}) = 50\,\text{m}$$

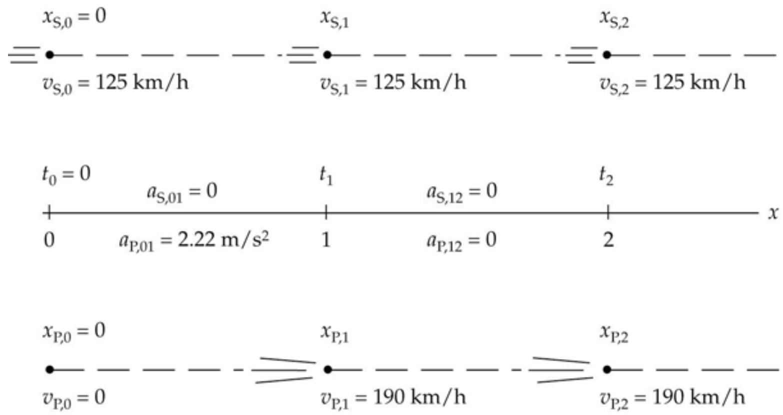
and that this distance is plotted above 10 s on the following graph.



Selecting additional points from the velocity graph and calculating the areas under the curve will confirm the graph of x as a function of t that is shown.

111 ••

Picture the Problem This is a two-stage constant-acceleration problem. Choose a coordinate system in which the direction of the motion of the cars is the positive direction. The pictorial representation summarizes what we know about the motion of the speeder's car and the patrol car.



Convert the speeds of the vehicles and the acceleration of the police car into SI units:

$$8\frac{\text{km}}{\text{h}\cdot\text{s}} = 8\frac{\text{km}}{\text{h}\cdot\text{s}} \times \frac{1\,\text{h}}{3600\,\text{s}} = 2.22\,\text{m/s}^2,$$

$$125\frac{\text{km}}{\text{h}} = 125\frac{\text{km}}{\text{h}} \times \frac{1\,\text{h}}{3600\,\text{s}} = 34.7\,\text{m/s},$$

and

$$190\frac{\text{km}}{\text{h}} = 190\frac{\text{km}}{\text{h}} \times \frac{1\,\text{h}}{3600\,\text{s}} = 52.8\,\text{m/s}$$

(*a*) Express the condition that determines when the police car catches the speeder; i.e., that their displacements will be the same:

$$\Delta x_{P,02} = \Delta x_{S,02}$$

Using a constant-acceleration equation, relate the displacement of the patrol car to its displacement while accelerating and its displacement once it reaches its maximum velocity:

$$\begin{aligned}\Delta x_{P,02} &= \Delta x_{P,01} + \Delta x_{P,12} \\ &= \Delta x_{P,01} + v_{P,1}(t_2 - t_1)\end{aligned}$$

Using a constant-acceleration equation, relate the displacement of the speeder to its constant velocity and the time it takes the patrol car to catch it:

$$\begin{aligned}\Delta x_{S,02} &= v_{S,02}\Delta t_{02} \\ &= (34.7\,\text{m/s})t_2\end{aligned}$$

Calculate the time during which the police car is speeding up:

$$\begin{aligned}\Delta t_{P,01} &= \frac{\Delta v_{P,01}}{a_{P,01}} = \frac{v_{P,1} - v_{P,0}}{a_{P,01}} \\ &= \frac{52.8\,\text{m/s} - 0}{2.22\,\text{m/s}^2} = 23.8\,\text{s}\end{aligned}$$

Express the displacement of the patrol car:

$$\Delta x_{\text{P},01} = v_{\text{P},0}\Delta t_{\text{P},01} + \tfrac{1}{2}a_{\text{P},01}\Delta t_{\text{P},01}^2 = 0 + \tfrac{1}{2}\left(2.22\ \text{m/s}^2\right)\left(23.8\ \text{s}\right)^2 = 629\ \text{m}$$

Equate the displacements of the two vehicles:

$$\Delta x_{\text{P},02} = \Delta x_{\text{P},01} + \Delta x_{\text{P},12} = \Delta x_{\text{P},01} + v_{\text{P},1}\left(t_2 - t_1\right) = 629\ \text{m} + \left(52.8\ \text{m/s}\right)\left(t_2 - 23.8\ \text{s}\right)$$

Solve for the time to catch up to obtain:

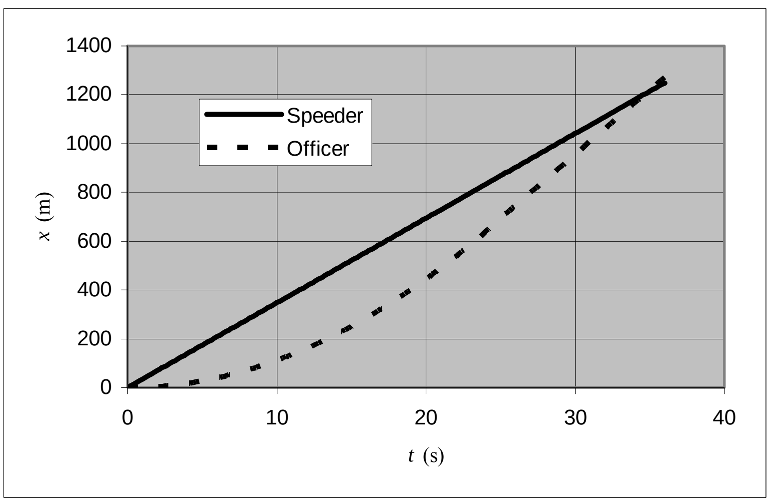
$$(34.7\ \text{m/s})\ t_2 = 629\ \text{m} + (52.8\ \text{m/s})(t_2 - 23.8\ \text{s})$$

$$\therefore\ t_2 = \boxed{34.7\ \text{s}}$$

(*b*) The distance traveled is the displacement, $\Delta x_{02,\text{S}}$, of the speeder during the catch:

$$\Delta x_{\text{S},02} = v_{\text{S},02}\Delta t_{02} = \left(34.7\ \text{m/s}\right)\left(34.7\ \text{s}\right) = \boxed{1.20\ \text{km}}$$

(*c*) The graphs of x_S and x_P are shown below. The straight line (solid) represents $x_\text{S}(t)$ and the parabola (dashed) represents $x_\text{P}(t)$.



112 ••

Picture the Problem The accelerations of both cars are constant and we can use constant-acceleration equations to describe their motions. Choose a coordinate system in which the direction of motion of the cars is the positive direction, and the origin is at the initial position of the police car.

(*a*) The collision will ***not*** occur if, during braking, the displacements of the two cars differ by less than 100 m.

$$\Delta x_\text{P} - \Delta x_\text{S} < 100\ \text{m}.$$

Using a constant-acceleration equation, relate the speeder's initial and final speeds to its displacement and acceleration and solve for the displacement:

$$v_s^2 = v_{0,s}^2 + 2a_s\Delta x_s$$

or, because $v_s = 0$,

$$\Delta x_s = \frac{-v_{0,s}^2}{2a_s}$$

Substitute numerical values and evaluate Δx_S:

$$\Delta x_S = \frac{-(34.7\ \text{m/s})^2}{2(-6\ \text{m/s}^2)} = 100\ \text{m}$$

Using a constant-acceleration equation, relate the patrol car's initial and final speeds to its displacement and acceleration and solve for the displacement:

$$v_p^2 = v_{0,p}^2 + 2a_p\Delta x_p$$

or, assuming $v_p = 0$,

$$\Delta x_p = \frac{-v_{0,p}^2}{2a_p}$$

Substitute numerical values and evaluate Δx_p:

$$\Delta x_P = \frac{-(52.8\ \text{m/s})^2}{2(-6\ \text{m/s}^2)} = 232\ \text{m}$$

Finally, substitute these displacements into the inequality that determines whether a collision occurs:

232 m – 100 m = 132 m

Because this difference is greater than 100 m, $\boxed{\text{the cars collide}}$.

(*b*) Using constant-acceleration equations, relate the positions of both vehicles to their initial positions, initial velocities, accelerations, and time in motion:

$$x_S = 100\ \text{m} + (34.7\ \text{m/s})t - (3\ \text{m/s}^2)t^2$$

and

$$x_P = (52.8\ \text{m/s})t - (3\ \text{m/s}^2)t^2$$

Equate these expressions and solve for *t*:

$$100\ \text{m} + (34.7\ \text{m/s})\,t - (3\ \text{m/s}^2)\,t^2 = (52.8\ \text{m/s})\,t - (3\text{m/s}^2)\,t^2$$

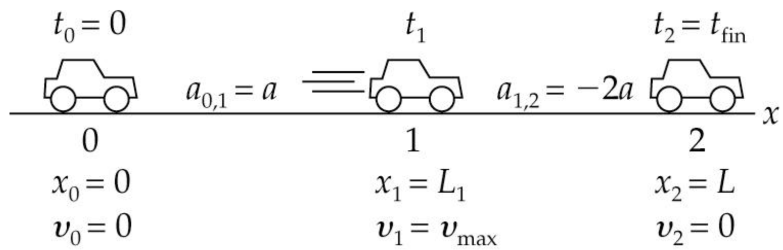
and

$$t = \boxed{5.52\ \text{s}}$$

(*c*) $\boxed{\text{If you take the reaction time into account, the collision will occur sooner and be more severe.}}$

113 ••

Picture the Problem Lou's acceleration is constant during both parts of his trip. Let t_1 be the time when the brake is applied; L_1 the distance traveled from $t = 0$ to $t = t_1$. Let t_{fin} be the time when Lou's car comes to rest at a distance L from the starting line. A pictorial representation will help organize the given information and plan the solution.



(*a*) Express the total length, *L*, of the course in terms of the distance over which Lou will be accelerating, Δx_{01}, and the distance over which he will be braking, Δx_{12}:

$$L = \Delta x_{01} + \Delta x_{12}$$

Express the final velocity over the first portion of the course in terms of the initial velocity, acceleration, and displacement; solve for the displacement:

$$v_1^2 = v_0^2 + 2a_{01}\Delta x_{01}$$

or, because $v_0 = 0$, $\Delta x_{01} = L_1$, and $a_{01} = a$,

$$\Delta x_{01} = L_1 = \frac{v_1^2}{2a} = \frac{v_{max}^2}{2a}$$

Express the final velocity over the second portion of the course in terms of the initial velocity, acceleration, and displacement; solve for the displacement:

$$v_2^2 = v_1^2 + 2a_{12}\Delta x_{12}$$

or, because $v_2 = 0$ and $a_{12} = -2a$,

$$\Delta x_{12} = \frac{v_1^2}{4a} = \frac{L_1}{2}$$

Substitute for Δx_{01} and Δx_{12} to obtain:

$$L = \Delta x_{01} + \Delta x_{12} = L_1 + \tfrac{1}{2}L_1 = \tfrac{3}{2}L_1$$

and

$$L_1 = \boxed{\tfrac{2}{3}L}$$

(*b*) Using the fact that the acceleration was constant during both legs of the trip, express Lou's average velocity over each leg:

$$v_{av,01} = v_{av,12} = \frac{v_{max}}{2}$$

Express the time for Lou to reach his maximum velocity as a function of L_1 and his maximum velocity:

$$\Delta t_{01} = \frac{\Delta x_{01}}{v_{av,01}} = \frac{2L_1}{v_{max}}$$

and

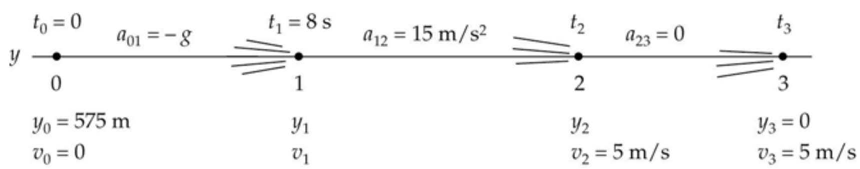
$$\Delta t_{01} \propto L_1 = \frac{2}{3}L$$

Having just shown that the time required for the first segment of the trip is proportional to the length of the segment, use this result to express Δt_{01} (= t_1) in terms t_{fin}:

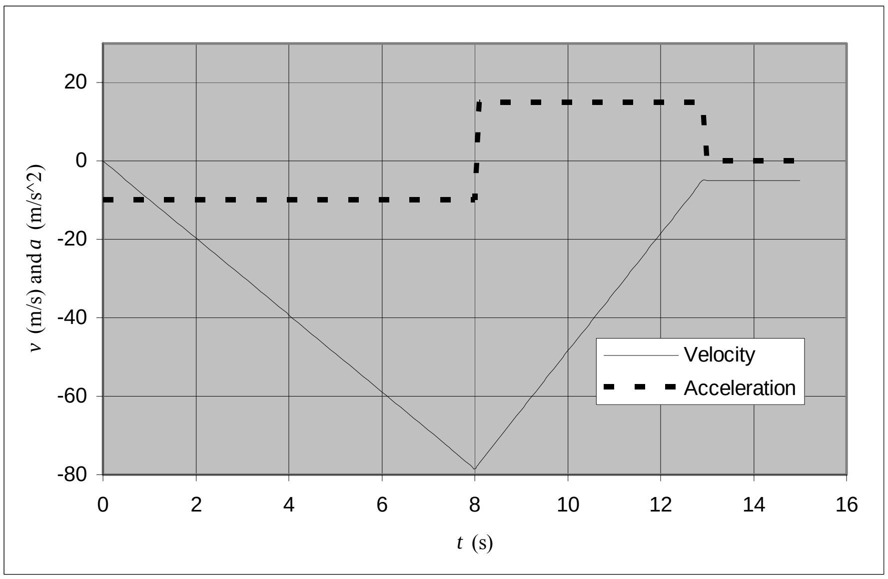
$$t = \boxed{\tfrac{2}{3}t_{fin}}$$

114 ••

Picture the Problem There are three intervals of constant acceleration described in this problem. Choose a coordinate system in which the upward direction (shown to the left below) is positive. A pictorial representation will help organize the details of the problem and plan the solution.



(*a*) The graphs of *a*(*t*) (dashed lines) and *v*(*t*) (solid lines) are shown below.



(*b*) Using a constant-acceleration equation, express her speed in terms of her acceleration and the elapsed time; solve for her speed after 8 s of fall:

$$v_1 = v_0 + a_{01}t_1 = 0 + (9.81\,\text{m/s}^2)(8\,\text{s}) = \boxed{78.5\,\text{m/s}}$$

(*c*) Using the same constant-acceleration equation that you used in part (*b*), determine the duration of her constant upward acceleration:

$$v_2 = v_1 + a_{12}\Delta t_{12}$$

$$\Delta t_{12} = \frac{v_2 - v_1}{a_{12}} = \frac{-5\,\text{m/s} - (-78.5\,\text{m/s})}{15\,\text{m/s}^2} = \boxed{4.90\,\text{s}}$$

(*d*) Find her average speed as she slows from 78.5 m/s to 5 m/s:

$$v_{av} = \frac{v_1 + v_2}{2} = \frac{78.5\,\text{m/s} + 5\,\text{m/s}}{2} = 41.8\,\text{m/s}$$

Use this value to calculate how far she travels in 4.90 s:

$$\Delta y_{12} = v_{av}\Delta t_{12} = (41.8\text{ m/s})(4.90\text{ s})$$
$$= 204\text{ m}$$

She travels 204 m while slowing down.

(*e*) Express the total time in terms of the times for each segment of her descent:

$$t_{total} = \Delta t_{01} + \Delta t_{12} + \Delta t_{23}$$

We know the times for the intervals from 0 to 1 and 1 to 2 so we only need to determine the time for the interval from 2 to 3. We can calculate Δt_{23} from her displacement and constant velocity during that segment of her descent.

$$\Delta y_{23} = \Delta y_{total} - \Delta y_{01} - \Delta y_{12}$$
$$= 575\text{ m} - \left(\frac{78.5\text{ m/s}}{2}\right)(8\text{ s}) - 204\text{ m}$$
$$= 57.0\text{ m}$$

Add the times to get the total time:

$$t_{total} = t_{01} + t_{12} + t_{23}$$
$$= 8\text{ s} + 4.9\text{ s} + \frac{57.0\text{ m}}{5\text{ m/s}}$$
$$= \boxed{24.3\text{ s}}$$

(*f*) Using its definition, calculate her average velocity:

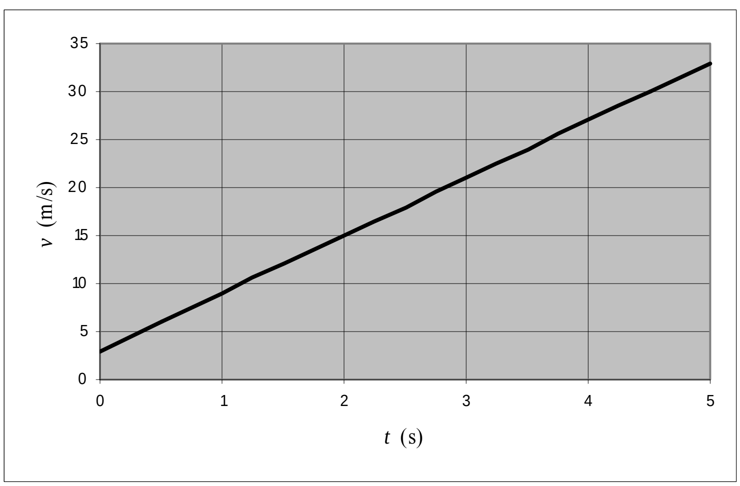
$$v_{av} = \frac{\Delta x}{\Delta t} = \frac{-1500\text{ m}}{209\text{ s}} = \boxed{-7.18\text{ m/s}}$$

Integration of the Equations of Motion

***115** •

Picture the Problem The integral of a function is equal to the "area" between the curve for that function and the independent-variable axis.

(*a*) The graph is shown below:



The distance is found by determining the area under the curve. You can accomplish this easily because the shape of the area under the curve is a trapezoid.

A = (36 blocks)(2.5 m/block) = $\boxed{90\text{ m}}$

or

$$A=\left(\frac{33\,\text{m/s}+3\,\text{m/s}}{2}\right)(5\,\text{s}-0\,\text{s})=90\,\text{m}$$

Alternatively, we could just count the blocks and fractions thereof.

There are approximately 36 blocks each having an area of (5 m/s)(0.5 s) = 2.5 m.

(b) To find the position function $x(t)$, we integrate the velocity function $v(t)$ over the time interval in question:

$$x(t)=\int_0^t v(t')\text{d}t'$$

$$=\int_0^t \left[\left(6\,\text{m/s}^2\right)t'+(3\,\text{m/s})\right]\text{d}t'$$

and

$$\boxed{x(t)=\left(3\,\text{m/s}^2\right)t^2+(3\,\text{m/s})t}$$

Now evaluate $x(t)$ at 0 s and 5 s respectively and subtract to obtain Δx:

$$\Delta x = x(5\,\text{s})-x(0\,\text{s})=90\text{ m}-0\text{ m}$$

$$=\boxed{90.0\,\text{m}}$$

116 •

Picture the Problem The integral of $v(t)$ over a time interval is the displacement (change in position) during that time interval. The integral of a function is equivalent to the "area" between the curve for that function and the independent-variable axis. Count the grid boxes.

(a) Find the area of the shaded gridbox:

$$Area=(1\,\text{m/s})(1\,\text{s})=\boxed{1\,\text{m per box}}$$

(b) Find the approximate area under curve for 1 s $\le t \le$ 2 s:

$$\Delta x_{1\text{ s to }2\text{ s}}=\boxed{1.2\,\text{m}}$$

Find the approximate area under curve for 2 s $\le t \le$ 3 s:

$$\Delta x_{2\text{ s to }3\text{ s}}=\boxed{3.2\,\text{m}}$$

(c) Sum the displacements to obtain the total in the interval 1 s $\le t \le$ 3 s:

$$\Delta x_{1\text{ s to }3\text{ s}}=1.2\text{ m}+3.2\text{ m}$$
$$=4.4\text{ m}$$

Using its definition, express and evaluate v_{av}:

$$v_{\text{av}}=\frac{\Delta x_{1\,\text{s to }3\,\text{s}}}{\Delta t_{1\,\text{s to }3\,\text{s}}}=\frac{4.4\,\text{m}}{2\,\text{s}}=\boxed{2.20\,\text{m/s}}$$

(d) Because the velocity of the particle is dx/dt, separate the

$$dx=\left(0.5\text{m/s}^3\right)dt$$

so

variables and integrate over the interval 1 s ≤ t ≤ 3 s to determine the displacement in this time interval:

$$\Delta x_{1\text{s}\to 3\text{s}} = \int_{x_0}^{x} dx' = \left(0.5\text{m/s}^3\right)\int_{1\,\text{s}}^{3\,\text{s}} t'^2\, dt'$$

$$= \left(0.5\text{m/s}^3\right)\left[\frac{t'^3}{3}\right]_{1\text{s}}^{3\text{s}} = \boxed{4.33\text{m}}$$

This result is a little smaller than the sum of the displacements found in part (*b*).

Calculate the average velocity over the 2-s interval from 1 s to 3 s:

$$v_{\text{av}\,(1\text{s}-3\text{s})} = \frac{\Delta x_{1\text{s}-3\text{s}}}{\Delta t_{1\text{s}-3\text{s}}} = \frac{4.33\text{m}}{2\text{s}} = 2.17\text{m/s}$$

Calculate the initial and final velocities of the particle over the same interval:

$$v(1\,\text{s}) = \left(0.5\,\text{m/s}^3\right)(1\,\text{s})^2 = 0.5\,\text{m/s}$$

$$v(3\,\text{s}) = \left(0.5\,\text{m/s}^3\right)(3\,\text{s})^2 = 4.5\,\text{m/s}$$

Finally, calculate the average value of the velocities at $t = 1$ s and $t = 3$ s:

$$\frac{v(1\,\text{s}) + v(3\,\text{s})}{2} = \frac{0.5\,\text{m/s} + 4.5\,\text{m/s}}{2}$$

$$= 2.50\,\text{m/s}$$

This average is not equal to the average velocity calculated above.

Remarks: The fact that the average velocity was not equal to the average of the velocities at the beginning and the end of the time interval in part (*d*) is a consequence of the acceleration not being constant.

***117** ••

Picture the Problem Because the velocity of the particle varies with the square of the time, the acceleration is not constant. The displacement of the particle is found by integration.

Express the velocity of a particle as the derivative of its position function:

$$v(t) = \frac{dx(t)}{dt}$$

Separate the variables to obtain:

$$dx(t) = v(t)dt$$

Express the integral of x from $x_o = 0$ to x and t from $t_0 = 0$ to t:

$$x(t) = \int_{t_0=0}^{x(t)} dx' = \int_{t_0=0}^{t} v(t')dt'$$

Substitute for $v(t')$ to obtain:

$$x(t) = \int_{t_0=0}^{t} \left[\left(7\,\text{m/s}^3\right)t'^2 - (5\,\text{m/s})\right]dt'$$

$$= \boxed{\left(\tfrac{7}{3}\,\text{m/s}^3\right)t^3 - (5\,\text{m/s})t}$$

118 ••

Picture the Problem The graph is one of constant negative acceleration. Because

$v_x = v(t)$ is a linear function of t, we can make use of the slope-intercept form of the equation of a straight line to find the relationship between these variables. We can then differentiate $v(t)$ to obtain $a(t)$ and integrate $v(t)$ to obtain $x(t)$.

Find the acceleration (the slope of the graph) and the velocity at time 0 (the v-intercept) and use the slope-intercept form of the equation of a straight line to express $v_x(t)$:

$$\boxed{a = -10\,\text{m/s}^2}$$

$$\boxed{v_x(t) = 50\,\text{m/s} + (-10\,\text{m/s}^2)t}$$

Find $x(t)$ by integrating $v(t)$:

$$x(t) = \int \left[\left(-10\,\text{m/s}^2\right)t + 50\,\text{m/s}\right]dt$$
$$= (50\,\text{m/s})t - \left(5\,\text{m/s}^2\right)t^2 + C$$

Using the fact that $x = 0$ when $t = 0$, evaluate C:

$$0 = (50\,\text{m/s})(0) - \left(5\,\text{m/s}^2\right)(0)^2 + C$$

and

$C = 0$

Substitute to obtain:

$$\boxed{x(t) = (50\,\text{m/s})t - \left(5\,\text{m/s}^2\right)t^2}$$

Note that this expression is quadratic in t and that the coefficient of t^2 is negative and equal in magnitude to half the constant acceleration.

Remarks: We can check our result for $x(t)$ by evaluating it over the 10-s interval shown and comparing this result with the area bounded by this curve and the time axis.

119 •••

Picture the Problem During any time interval, the integral of $a(t)$ is the change in velocity and the integral of $v(t)$ is the displacement. The integral of a function equals the "area" between the curve for that function and the independent-variable axis.

(*a*) Find the area of the shaded grid box in Figure 2-37:

Area = (0.5 m/s²)(0.5 s)

$$= \boxed{0.250\,\text{m/s per box}}$$

(*b*) We start from rest ($v_0 = 0$) at $t = 0$. For the velocities at the other times, count boxes and multiply by the 0.25 m/s per box that we found in part (*a*):

Examples:

$v(1\text{ s})$ = (3.7 boxes)[(0.25 m/s)/box]

$$= \boxed{0.925\,\text{m/s}}$$

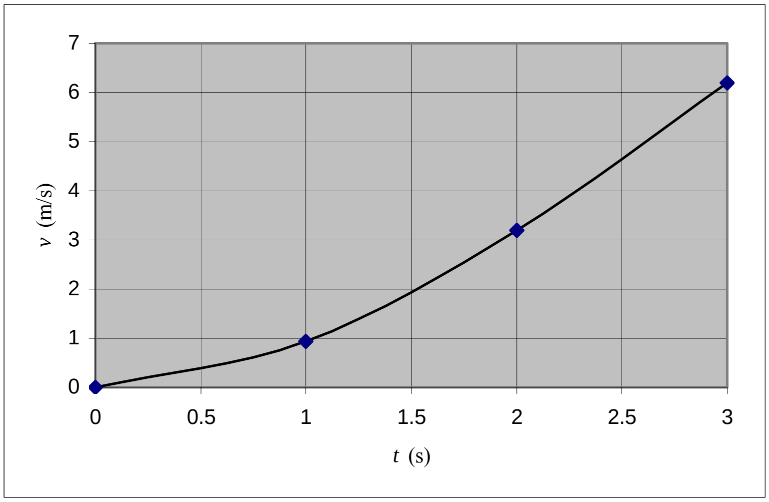
$v(2\text{ s})$ = (12.9 boxes)[(0.25 m/s)/box]

$$= \boxed{3.22\,\text{m/s}}$$

and

$$v(3\text{ s}) = (24.6\text{ boxes})[(0.25\text{ m/s})/\text{box}]$$
$$= \boxed{6.15\text{ m/s}}$$

(*c*) The graph of *v* as a function of *t* is shown below:



$$Area = (1.0\text{ m/s})(1.0\text{ s}) = 1.0\text{ m per box}$$

Count the boxes under the *v*(*t*) curve to find the distance traveled:

$$x(3\text{ s}) = \Delta x(0 \to 3\text{ s})$$
$$= (7\text{ boxes})[(1.0\text{ m})/\text{box}]$$
$$= \boxed{7.00\text{ m}}$$

120 ••

Picture the Problem The integral of *v*(*t*) over a time interval is the displacement (change in position) during that time interval. The integral of a function equals the "area" between the curve for that function and the independent-variable axis. Because acceleration is the slope of a velocity versus time curve, this is a non-constant-acceleration problem. The derivative of a function is equal to the "slope" of the function at that value of the independent variable.

(*a*) To obtain the data for *x*(*t*), we must estimate the accumulated area under the *v*(*t*) curve at each time interval:

Find the area of a shaded grid box in Figure 2-38:

$$A = (1\text{ m/s})(0.5\text{ s}) = 0.5\text{ m per box.}$$

We start from rest ($v_o = 0$) at $t_o = 0$. For the position at the other times, count boxes and multiply by the 0.5 m per box that we found above. Remember to add the offset from the origin, $x_o = 5$ m, and that boxes below the $v = 0$ line are counted as negative:

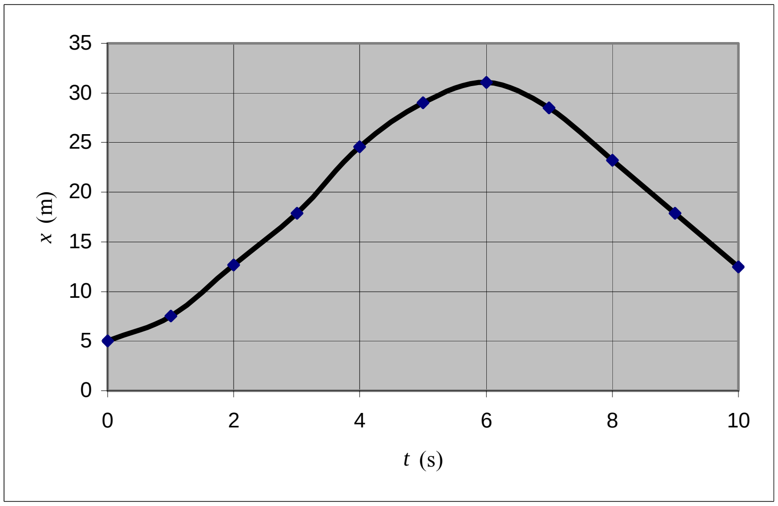
Examples:

$$x(3\text{ s}) = (25.8\text{ boxes})\left(\frac{0.5\text{ m}}{\text{box}}\right) + 5\text{ m}$$
$$= 17.9\text{ m}$$

$$x(5\text{ s}) = (48.0\text{ boxes})\left(\frac{0.5\text{ m}}{\text{box}}\right) + 5\text{ m}$$
$$= 29.0\text{ m}$$

$$x(10\,\text{s}) = (51.0\,\text{boxes})\left(\frac{0.5\,\text{m}}{\text{box}}\right) - (36.0\,\text{boxes})\left(\frac{0.5\,\text{m}}{\text{box}}\right) + 5\,\text{m}$$
$$= 12.5\,\text{m}$$

A graph of *x* as a function of *t* follows:

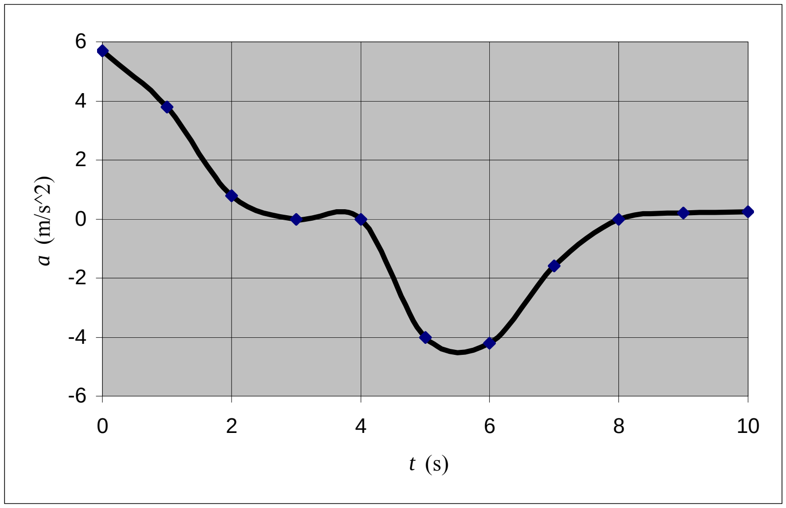


(*b*) To obtain the data for *a*(*t*), we must estimate the slope ($\Delta v/\Delta t$) of the *v*(*t*) curve at each time. A good way to get reasonably reliable readings from the graph is to enlarge several fold:

Examples:

$$a(1\,\text{s}) = \frac{v(1.25\,\text{s}) - v(0.75\,\text{s})}{0.5\,\text{s}}$$
$$= \frac{4.9\,\text{m/s} - 3.0\,\text{m/s}}{0.5\,\text{s}} = 3.8\,\text{m/s}^2$$
$$a(6\,\text{s}) = \frac{v(6.25\,\text{s}) - v(5.75\,\text{s})}{0.5\,\text{s}}$$
$$= \frac{-1.7\,\text{m/s} - 0.4\,\text{m/s}}{0.5\,\text{s}} = -4.2\,\text{m/s}^2$$

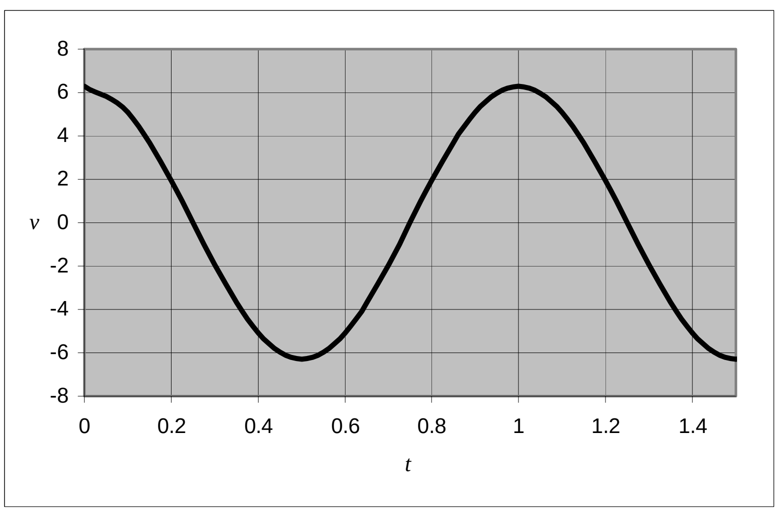
A graph of a as a function of t follows:



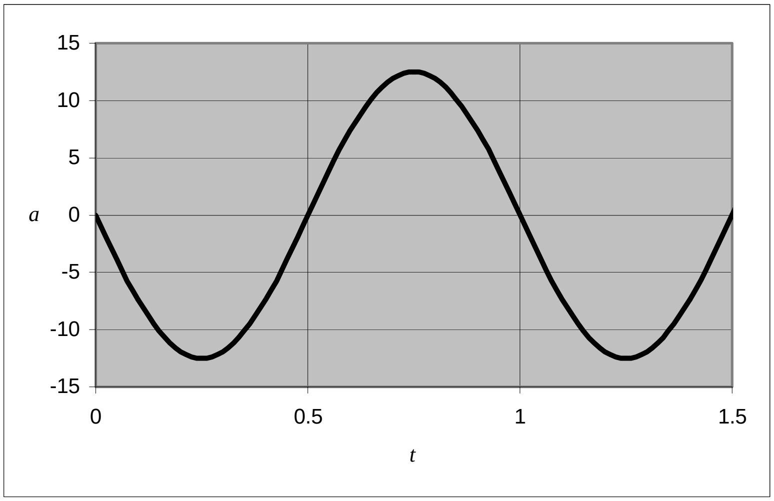
***121** ••

Picture the Problem Because the position of the body is not described by a parabolic function, the acceleration is not constant.

Select a series of points on the graph of $x(t)$ (e.g., at the extreme values and where the graph crosses the t axis), draw tangent lines at those points, and measure their slopes. In doing this, you are evaluating $v = dx/dt$ at these points. Plot these slopes above the times at which you measured the slopes. Your graph should closely resemble the following graph.



Select a series of points on the graph of $v(t)$ (e.g., at the extreme values and where the graph crosses the t axis), draw tangent lines at those points, and measure their slopes. In doing this, you are evaluating $a = dv/dt$ at these points. Plot these slopes above the times at which you measured the slopes. Your graph should closely resemble the graph shown below.



122 ••

Picture the Problem Because the acceleration of the rocket varies with time, it is not constant and integration of this function is required to determine the rocket's velocity and position as functions of time. The conditions on x and v at $t = 0$ are known as ***initial conditions***.

(*a*) Integrate $a(t)$ to find $v(t)$:

$$v(t) = \int a(t)\,dt = b\int t\,dt = \tfrac{1}{2}bt^2 + \mathrm{C}$$

where C, the constant of integration, can be determined from the initial conditions.

Integrate $v(t)$ to find $x(t)$:

$$x(t) = \int v(t)dt = \int\left[\tfrac{1}{2}bt^2 + \mathrm{C}\right]dt = \tfrac{1}{6}bt^3 + \mathrm{C}t + \mathrm{D}$$

where D is a second constant of integration.

Using the initial conditions, find the constants C and D:

$$v(0) = 0 \;\Rightarrow\; \mathrm{C} = 0$$

and

$$x(0) = 0 \;\Rightarrow\; \mathrm{D} = 0$$

$$\therefore \boxed{x(t) = \tfrac{1}{6}bt^3}$$

(*b*) Evaluate $v(5\text{ s})$ and $x(5\text{ s})$ with $\mathrm{C} = \mathrm{D} = 0$ and $b = 3\text{ m/s}^2$:

$$v(5\text{ s}) = \frac{1}{2}(3\text{m/s}^2)(5\text{s})^2 = \boxed{37.5\text{ m/s}}$$

and

$$x(5\text{ s}) = \frac{1}{6}(3\text{m/s}^2)(5\text{s})^3 = \boxed{62.5\text{ m}}$$

123 ••

Picture the Problem The acceleration is a function of time; therefore it is not constant. The instantaneous velocity can be determined by integration of the acceleration and the average velocity from the displacement of the particle during the given time interval.

(*a*) Because the acceleration is the derivative of the velocity, integrate the acceleration to find the ***instantaneous velocity*** $v(t)$.

$$a(t)=\frac{dv}{dt}\Rightarrow v(t)=\int_{v_0=0}^{v(t)}dv'=\int_{t_0=0}^{t}a(t')dt'$$

Calculate the instantaneous velocity using the acceleration given.

$$v(t)=\left(0.2\,\text{m/s}^3\right)\int_{t_0=0}^{t}t'dt'$$

and

$$\boxed{v(t)=\left(0.1\,\text{m/s}^3\right)t^2}$$

(*b*) To calculate the ***average velocity***, we need the displacement:

$$v(t)\equiv\frac{dx}{dt}\Rightarrow x(t)=\int_{x_0=0}^{x(t)}dx'=\int_{t_0=0}^{t}v(t')dt'$$

Because the velocity is the derivative of the displacement, integrate the velocity to find Δx.

$$x(t)=\left(0.1\,\text{m/s}^3\right)\int_{t_0=0}^{t}t'^2\,dt'=\left(0.1\,\text{m/s}^3\right)\frac{t^3}{3}$$

and

$$\begin{aligned}\Delta x&=x(7\text{ s})-x(2\text{ s})\\&=\left(0.1\,\text{m/s}^3\right)\left[\frac{(7\text{ s})^3-(2\text{ s})^3}{3}\right]\\&=11.2\text{ m}\end{aligned}$$

Using the definition of the ***average velocity***, calculate v_{av}.

$$v_{\text{av}}=\frac{\Delta x}{\Delta t}=\frac{11.2\text{ m}}{5\text{ s}}=\boxed{2.23\text{ m/s}}$$

124 •

Determine the Concept Because the acceleration is a function of time, it is not constant. Hence we'll need to integrate the acceleration function to find the velocity as a function of time and integrate the velocity function to find the position as a function of time. The important concepts here are the definitions of velocity, acceleration, and average velocity.

(*a*) Starting from $t_o = 0$, integrate the instantaneous acceleration to obtain the instantaneous velocity as a function of time:

From $a=\dfrac{dv}{dt}$

it follows that

$$\int_{v_0}^{v}dv'=\int_{0}^{t}(a_0+bt')dt'$$

and

$$\boxed{v=v_0+a_0t+\tfrac{1}{2}bt^2}$$

(*b*) Now integrate the instantaneous velocity to obtain the position as a function of time:

From $v=\dfrac{dx}{dt}$

it follows that

$$\int_{x_0}^{x} dx' = \int_{t_0=0}^{t} v(t')\,dt'$$
$$= \int_{t_0}^{t}\left(v_9 + a_0 t' + \frac{b}{2}t'^2\right)dt'$$

and

$$\boxed{x = x_0 + v_0 t + \tfrac{1}{2}a_0 t^2 + \tfrac{1}{6}bt^3}$$

(*c*) The definition of the average velocity is the ratio of the displacement to the total time elapsed:

$$v_{av} \equiv \frac{\Delta x}{\Delta t} = \frac{x - x_0}{t - t_0} = \frac{v_0 t + \tfrac{1}{2}a_0 t^2 + \tfrac{1}{6}bt^3}{t}$$

and

$$\boxed{v_{av} = v_0 + \tfrac{1}{2}a_0 t + \tfrac{1}{6}bt^2}$$

Note that v_{av} is not the same as that due to constant acceleration:

$$\left(v_{\text{constant acceleration}}\right)_{av} = \frac{v_0 + v}{2}$$
$$= \frac{v_0 + \left(v_0 + a_0 t + \tfrac{1}{2}bt^2\right)}{2}$$
$$= v_0 + \tfrac{1}{2}a_0 t + \tfrac{1}{4}bt^2$$
$$\neq v_{av}$$

General Problems

125 •••

Picture the Problem The acceleration of the marble is constant. Because the motion is downward, choose a coordinate system with downward as the positive direction. The equation $g_{exp} = (1\text{ m})/(\Delta t)^2$ originates in the constant-acceleration equation $\Delta x = v_0\Delta t + \tfrac{1}{2}a(\Delta t)^2$. Because the motion starts from rest, the displacement of the marble is 1 m, the acceleration is the experimental value g_{exp}, and the equation simplifies to $g_{exp} = (1\text{ m})/(\Delta t)^2$.

Express the percent difference between the accepted and experimental values for the acceleration due to gravity:

$$\%\text{ difference} = \frac{\left|g_{accepted} - g_{exp}\right|}{g_{accepted}}$$

Using a constant-acceleration equation, express the velocity of the marble in terms of its initial velocity, acceleration, and displacement:

$$v_f^2 = v_0^2 + 2a\Delta y$$

or, because $v_0 = 0$ and $a = g$,

$$v_f^2 = 2g\Delta y$$

Solve for v_f:

$$v_f = \sqrt{2g\Delta y}$$

Let v_1 be the velocity the ball has reached when it has fallen 0.5 cm,

$$v_1 = \sqrt{2\left(9.81\text{ m/s}^2\right)\left(0.005\text{ m}\right)} = 0.313\text{ m/s}$$

and v_2 be the velocity the ball has reached when it has fallen 0.5 m to obtain.

and

$$v_2 = \sqrt{2(9.81\,\text{m/s}^2)(0.5\,\text{m})} = 3.13\,\text{m/s}$$

Using a constant-acceleration equation, express v_2 in terms of v_1, g and Δt:

$$v_2 = v_1 + g\Delta t$$

Solve for Δt:

$$\Delta t = \frac{v_2 - v_1}{g}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{3.13\,\text{m/s} - 0.313\,\text{m/s}}{9.81\,\text{m/s}^2} = 0.2872\,\text{s}$$

Calculate the experimental value of the acceleration due to gravity from $g_{\text{exp}} = (1\text{ m})/(\Delta t)^2$:

$$g_{\text{exp}} = \frac{1\,\text{m}}{(0.2872\,\text{s})^2} = \boxed{12.13\,\text{m/s}^2}$$

Finally, calculate the percent difference between this experimental result and the value accepted for g at sea level.

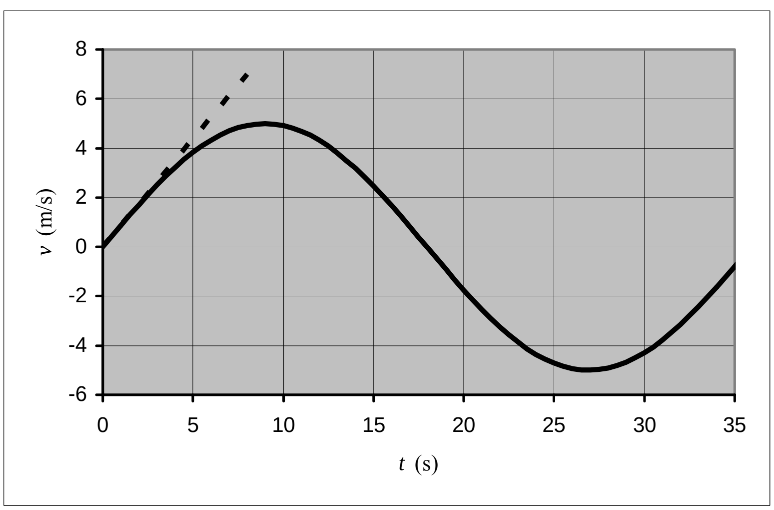
$$\%\text{ difference} = \frac{\left|9.81\,\text{m/s}^2 - 12.13\,\text{m/s}^2\right|}{9.81\,\text{m/s}^2}$$

$$= \boxed{23.6\,\%}$$

***126 •••**

Picture the Problem We can obtain an average velocity, $v_{\text{av}} = \Delta x/\Delta t$, over fixed time intervals. The instantaneous velocity, $v = dx/dt$ can only be obtained by differentiation.

(*a*) The graph of x versus t is shown below:



(*b*) Draw a tangent line at the origin and measure its rise and run. Use this ratio to obtain an approximate value for the slope at the origin:

The tangent line appears to, at least approximately, pass through the point (5, 4). Using the origin as the second point,

$$\Delta x = 4\text{ cm} - 0 = 4\text{ cm}$$

and

$$\Delta t = 5\text{ s} - 0 = 5\text{ s}$$

Therefore, the slope of the tangent line and the velocity of the body as it passes through the origin is approximately:

$$v(0) = \frac{\text{rise}}{\text{run}} = \frac{\Delta x}{\Delta t} = \frac{4\,\text{cm}}{5\,\text{s}} = \boxed{0.800\,\text{cm/s}}$$

(*c*) Calculate the average velocity for the series of time intervals given by completing the table shown below:

t_0	t	Δt	x_0	x	Δx	$v_{av}=\Delta x/\Delta t$
(s)	(s)	(s)	(cm)	(cm)	(cm)	(m/s)
0	6	6	0	4.34	4.34	0.723
0	3	3	0	2.51	2.51	0.835
0	2	2	0	1.71	1.71	0.857
0	1	1	0	0.871	0.871	0.871
0	0.5	0.5	0	0.437	0.437	0.874
0	0.25	0.25	0	0.219	0.219	0.875

(*d*) Express the time derivative of the position:

$$\frac{dx}{dt} = A\omega\cos\omega t$$

Substitute numerical values and evaluate $\frac{dx}{dt}$ at $t = 0$:

$$\frac{dx}{dt} = A\omega\cos 0 = A\omega$$

$$= (0.05\,\text{m})(0.175\,\text{s}^{-1})$$

$$= \boxed{0.875\,\text{cm/s}}$$

(*e*) Compare the average velocities from part (*c*) with the instantaneous velocity from part (*d*):

As Δt, and thus Δx, becomes small, the value for the average velocity approaches that for the instantaneous velocity obtained in part (*d*). For $\Delta t = 0.25$ s, they agree to three significant figures.

127 •••

Determine the Concept Because the velocity varies nonlinearly with time, the acceleration of the object is not constant. We can find the acceleration of the object by differentiating its velocity with respect to time and its position function by integrating the velocity function. The important concepts here are the definitions of acceleration and velocity.

(*a*) The acceleration of the object is the derivative of its velocity with respect to time:

$$a = \frac{dv}{dt} = \frac{d}{dt}\left[v_{\max}\sin(\omega t)\right]$$

$$= \boxed{\omega v_{\max}\cos(\omega t)}$$

Because a varies sinusoidally with time it is *not* constant.

(*b*) Integrate the velocity with respect to time from 0 to t to obtain the change in position of the body:

$$\int_{x_0}^{x} dx' = \int_{t_0}^{t} [v_{max} \sin(\omega t')] dt'$$

and

$$x - x_0 = \left[\frac{-v_{max}}{\omega}\cos(\omega t')\right]_0^t$$

$$= \frac{-v_{max}}{\omega}\cos(\omega t) + \frac{v_{max}}{\omega}$$

or

$$\boxed{x = x_0 + \frac{v_{max}}{\omega}[1 - \cos(\omega t)]}$$

Note that, as given in the problem statement, $x(0\text{ s}) = x_0$.

128 •••

Picture the Problem Because the acceleration of the particle is a function of its position, it is not constant. Changing the variable of integration in the definition of acceleration will allow us to determine its velocity and position as functions of position.

(*a*) Because $a = dv/dt$, we must integrate to find $v(t)$. Because a is given as a function of x, we'll need to change variables in order to carry out the integration. Once we've changed variables, we'll separate them with v on the left side of the equation and x on the right:

$$a = \frac{dv}{dt} = \frac{dv}{dx}\frac{dx}{dt} = v\frac{dv}{dx} = \left(2\,\text{s}^{-2}\right)x$$

or, upon separating variables,

$$vdv = \left(2\,\text{s}^{-2}\right)xdx$$

Integrate from x_o and v_o to x and v:

$$\int_{v_0=0}^{v} v'dv' = \int_{x_0}^{x} \left(2\,\text{s}^{-2}\right)x'dx'$$

and

$$v^2 - v_0^2 = \left(2\,\text{s}^{-2}\right)\left(x^2 - x_0^2\right)$$

Solve for v to obtain:

$$v = \sqrt{v_0^2 + \left(2\,\text{s}^{-2}\right)\left(x^2 - x_0^2\right)}$$

Now set $v_o = 0$, $x_o = 1$ m, $x = 3$ m, $b = 2\ \text{s}^{-2}$ and evaluate the speed:

$$v = \pm\sqrt{\left(2\,\text{s}^{-2}\right)\left[(3\,\text{m})^2 - (1\,\text{m})^2\right]}$$

and

$$|v| = \boxed{4.00\,\text{m/s}}$$

(*b*) Using the definition of *v*, separate the variables, and integrate to get an expression for *t*:

$$v(x)=\frac{dx}{dt}$$

and

$$\int_0^t dt' = \int_{x_0}^{x}\frac{dx'}{v(x')}$$

To evaluate this integral we first must find $v(x)$. Show that the acceleration is always positive and use this to find the sign of $v(x)$.

$a = (2\ \text{s}^{-2})x$ and $x_0 = 1$ m. x_0 is positive, so a_0 is also positive. v_0 is zero and a_0 is positive, so the object moves in the direction of increasing *x*. As *x* increases the acceleration remains positive, so the velocity also remains positive. Thus,

$$v=\sqrt{(2\,\text{s}^{-2})(x^2-x_0^2)}.$$

Substitute $\sqrt{(2\,\text{s}^{-2})(x^2-x_0^2)}$ for *v* and evaluate the integral. (It can be found in standard integral tables.)

$$t=\int_0^t dt' = \int_{x_0}^{x}\frac{dx'}{v(x')}$$

$$=\int_{x_0}^{x}\frac{dx'}{\sqrt{(2\,\text{s}^{-2})(x'^2-x_0^2)}}$$

$$=\frac{1}{\sqrt{(2\,\text{s}^{-2})}}\int_{x_0}^{x}\frac{dx'}{\sqrt{x'^2-x_0^2}}$$

$$=\frac{1}{\sqrt{(2\,\text{s}^{-2})}}\ln\left(\frac{x+\sqrt{x^2-x_0^2}}{x_0}\right)$$

Evaluate this expression with $x_o = 1$ m and $x = 3$ m to obtain:

$$t=\boxed{1.25\,\text{s}}$$

129 •••

Picture the Problem The acceleration of this particle is not constant. Separating variables and integrating will allow us to express the particle's position as a function of time and the differentiation of this expression will give us the acceleration of the particle as a function of time.

(*a*) Write the definition of velocity:

$$v=\frac{dx}{dt}$$

We are given that $x = bv$, where $b = 1$ s. Substitute for *v* and separate variables to obtain:

$$\frac{dx}{dt}=\frac{x}{b}\Rightarrow dt=b\frac{dx}{x}$$

Integrate and solve for $x(t)$:

$$\int_{t_0}^{t}dt'=b\int_{x_0}^{x}\frac{dx'}{x'}\Rightarrow (t-t_0)=b\ln\left(\frac{x}{x_0}\right)$$

and

$$x(t)=\boxed{x_0 e^{(t-t_0)/b}}$$

(*b*) Differentiate twice to obtain *v*(*t*) and *a*(*t*):

$$v=\frac{dx}{dt}=\frac{1}{b}x_0 e^{(t-t_0)/b}$$

and

$$a=\frac{dv}{dt}=\frac{1}{b^2}x_0 e^{(t-t_0)/b}$$

Substitute the result in part (*a*) to obtain the desired results:

$$v(t)=\frac{1}{b}x(t)$$

and

$$a(t)=\frac{1}{b^2}x(t)$$

so

$$a(t)=\frac{1}{b}v(t)=\frac{1}{b^2}x(t)$$

$$\boxed{\text{Because the numerical value of } b\text{, expressed in SI units, is one, the numerical values of } a, v, \text{and } x \text{ are the same at each instant in time.}}$$

130 •••

Picture the Problem Because the acceleration of the rock is a function of time, it is not constant. Choose a coordinate system in which downward is positive and the origin at the point of release of the rock.

Separate variables in $a(t)=dv/dt=ge^{-bt}$ to obtain:

$$dv=ge^{-bt}dt$$

Integrate from $t_o=0$, $v_o=0$ to some later time *t* and velocity *v*:

$$v=\int_0^v dv'=\int_0^t ge^{-bt'}dt'=\frac{g}{-b}\left[e^{-bt'}\right]_0^t$$

$$=\frac{g}{b}\left(1-e^{-bt}\right)=v_{\text{term}}\left(1-e^{-bt}\right)$$

where

$$v_{\text{term}}=\frac{g}{b}$$

Separate variables in $v=dy/dt=v_{\text{term}}\left(1-e^{-bt}\right)$ to obtain:

$$dy=v_{\text{term}}\left(1-e^{-bt}\right)dt$$

Integrate from $t_o=0$, $y_o=0$ to some later time *t* and position *y*:

$$\int_0^y dy'=\int_0^t v_{\text{term}}\left(1-e^{-bt'}\right)dt'$$

$$y = v_{\text{term}}\left[t' + \frac{1}{b}e^{-bt'}\right]_0^t$$

$$= \boxed{v_{\text{term}}t - \frac{v_{\text{term}}}{b}\left(1 - e^{-bt}\right)}$$

This last result is very interesting. It says that throughout its free-fall, the object experiences drag; therefore it has not fallen as far at any given time as it would have if it were falling at the constant velocity, v_{term}.

On the other hand, just as the velocity of the object asymptotically approaches v_{term}, the distance it has covered during its free-fall as a function of time asymptotically approaches the distance it would have fallen if it had fallen with v_{term} throughout its motion.

$$y\left(t_{\text{large}}\right) \to v_{\text{term}}t - \frac{v}{b} \to v_{\text{term}}t$$

This should not be surprising because in the expression above, the first term grows linearly with time while the second term approaches a constant and therefore becomes less important with time.

***131 •••**

Picture the Problem Because the acceleration of the rock is a function of its velocity, it is not constant. Choose a coordinate system in which downward is positive and the origin is at the point of release of the rock.

Rewrite $a = g - bv$ explicitly as a differential equation:

$$\frac{dv}{dt} = g - bv$$

Separate the variables, v on the left, t on the right:

$$\frac{dv}{g - bv} = dt$$

Integrate the left-hand side of this equation from 0 to v and the right-hand side from 0 to t:

$$\int_0^v \frac{dv'}{g - bv'} = \int_0^t dt'$$

and

$$-\frac{1}{b}\ln\left(\frac{g - bv}{g}\right) = t$$

Solve this expression for v.

$$v = \frac{g}{b}\left(1 - e^{-bt}\right)$$

Finally, differentiate this expression with respect to time to obtain an expression for the acceleration and

$$a = \frac{dv}{dt} = \boxed{ge^{-bt}}$$

complete the proof.

132 •••

Picture the Problem The skydiver's acceleration is a function of her velocity; therefore it is not constant. Expressing her acceleration as the derivative of her velocity, separating the variables, and then integrating will give her velocity as a function of time.

(*a*) Rewrite $a = g - cv^2$ explicitly as a differential equation:

$$\frac{dv}{dt} = g - cv^2$$

Separate the variables, with *v* on the left, and *t* on the right:

$$\frac{dv}{g - cv^2} = dt$$

Eliminate *c* by using $c = \frac{g}{v_T^2}$:

$$\frac{dv}{g - \frac{g}{v_T^2}v^2} = \frac{dv}{g\left[1 - \left(\frac{v}{v_T}\right)^2\right]} = dt$$

or

$$\frac{dv}{1 - \left(\frac{v}{v_T}\right)^2} = gdt$$

Integrate the left-hand side of this equation from 0 to *v* and the right-hand side from 0 to *t*:

$$\int_0^v \frac{dv'}{1 - \left(\frac{v'}{v_T}\right)^2} = g\int_0^t dt' = gt$$

The integral can be found in integral tables:

$$v_T \tanh^{-1}(v/v_T) = gt$$

or

$$\tanh^{-1}(v/v_T) = (g/v_T)t$$

Solve this equation for *v* to obtain:

$$v = v_T \tanh\left(\frac{g}{v_T}\right)t$$

Because *c* has units of m^{-1}, and *g* has units of m/s^2, $(cg)^{-1/2}$ will have units of time. Let's represent this expression with the time-scale factor *T*:

i.e., $T = (cg)^{-1/2}$

The skydiver falls with her terminal velocity when $a = 0$. Using this definition, relate her terminal velocity to the acceleration due to gravity and the constant c in the acceleration equation:

$$0 = g - cv_T^2$$

and

$$v_T = \sqrt{\frac{g}{c}}$$

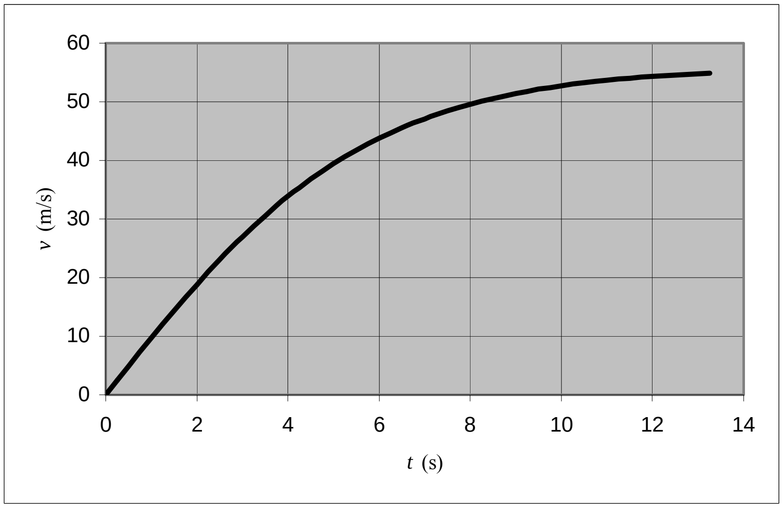
Convince yourself that T is also equal to v_T/g and use this relationship to eliminate g and v_T in the solution to the differential equation:

$$v(t) = \boxed{v_T \tanh\left(\frac{t}{T}\right)}$$

(*b*) The following table was generated using a spreadsheet and the equation we derived in part (*a*) for $v(t)$. The cell formulas and their algebraic forms are:

Cell	Content/Formula	Algebraic Form
D1	56	v_T
D2	5.71	T
B7	B6 + 0.25	$t + 0.25$
C7	$B$1*TANH(B7/$B$2)	$v_T \tanh\left(\frac{t}{T}\right)$

	A	B	C	D	E
1	vT =	56	m/s		
2	T=	5.71	s		
3					
4					
5		time (s)	*v* (m/s)		
6		0.00	0.00		
7		0.25	2.45		
8		0.50	4.89		
9		0.75	7.32		
10		1.00	9.71		
54		12.00	54.35		
55		12.25	54.49		
56		12.50	54.61		
57		12.75	54.73		
58		13.00	54.83		
59		13.25	54.93		



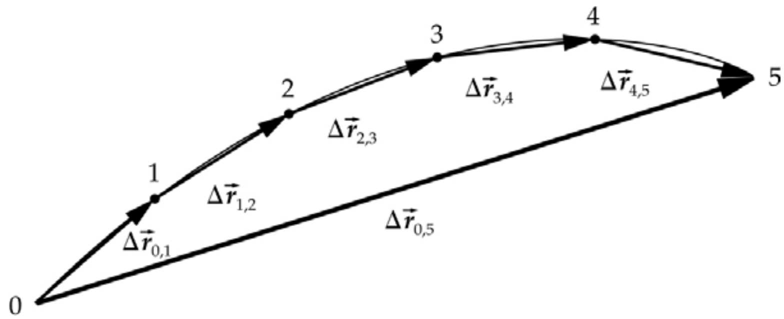
Note that the velocity increases linearly over time (i.e., with constant acceleration) for about time *T*, but then it approaches the terminal velocity as the acceleration decreases.

Chapter 3
Motion in Two and Three Dimensions

Conceptual Problems

***1 •**

Determine the Concept The distance traveled along a path can be represented as a sequence of displacements.



Suppose we take a trip along some path and consider the trip as a sequence of many very small displacements. The net displacement is the vector sum of the very small displacements, and the total distance traveled is the sum of the magnitudes of the very small displacements. That is,

$$\textit{total distance} = \left|\Delta\vec{r}_{0,1}\right| + \left|\Delta\vec{r}_{1,2}\right| + \left|\Delta\vec{r}_{2,3}\right| + \ldots + \left|\Delta\vec{r}_{N-1,N}\right|$$

where N is the number of very small displacements. (For this to be exactly true we have to take the limit as N goes to infinity and each displacement magnitude goes to zero.) Now, using "the shortest distance between two points is a straight line," we have

$$\left|\Delta\vec{r}_{0,N}\right| \le \left|\Delta\vec{r}_{0,1}\right| + \left|\Delta\vec{r}_{1,2}\right| + \left|\Delta\vec{r}_{2,3}\right| + \ldots + \left|\Delta\vec{r}_{N-1,N}\right|,$$

where $\left|\Delta\vec{r}_{0,N}\right|$ is the magnitude of the net displacement.

Hence, we have shown that the magnitude of the displacement of a particle is less than or equal to the distance it travels along its path.

2 •

Determine the Concept The displacement of an object is its final position vector minus its initial position vector ($\Delta\vec{r} = \vec{r}_f - \vec{r}_i$). The displacement can be less but never more than the distance traveled. Suppose the path is one complete trip around the earth at the equator. Then, the displacement is 0 but the distance traveled is $2\pi R_e$.

3 •

Determine the Concept The important distinction here is that ***average velocity*** is being requested, as opposed to ***average speed***.

The average velocity is defined as the displacement divided by the elapsed time.

$$\vec{v}_{av} = \frac{\Delta\vec{r}}{\Delta t} = \frac{0}{\Delta t} = 0$$

The displacement for any trip around the track is zero. Thus we see that no matter how fast the race car travels, the average velocity is always zero at the end of each complete circuit.

What is the correct answer if we were asked for *average speed*?

The average speed is defined as the distance traveled divided by the elapsed time.

$$v_{av} \equiv \frac{\text{total distance}}{\Delta t}$$

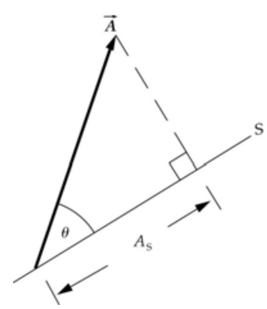
For one complete circuit of any track, the total distance traveled will be greater than zero and the average is not zero.

4 •

False. Vectors are quantities with magnitude and direction that can be added and subtracted like displacements. Consider two vectors that are equal in magnitude and oppositely directed. Their sum is zero, showing by counterexample that *the statement is false.*

5 •

Determine the Concept We can answer this question by expressing the relationship between the magnitude of vector $\vec{A}$ and its component A_S and then using properties of the cosine function.



Express A_S in terms of A and θ:

$$A_S = A\cos\theta$$

Take the absolute value of both sides of this expression:

$$|A_S| = |A\cos\theta| = A|\cos\theta|$$

and

$$|\cos\theta| = \frac{|A_S|}{A}$$

Using the fact that $0 < |\cos\theta| \le 1$, substitute for $|\cos\theta|$ to obtain:

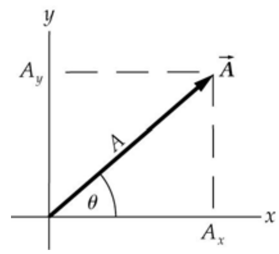
$$0 < \frac{|A_S|}{A} \le 1 \text{ or } 0 < |A_S| \le A$$

No. The magnitude of a component of a vector must be less than or equal to the magnitude of the vector.

If the angle θ shown in the figure is equal to 0° or multiples of 180°, then the magnitude of the vector and its component are equal.

***6** •

Determine the Concept The diagram shows a vector $\vec{A}$ and its components A_x and A_y. We can relate the magnitude of $\vec{A}$ is related to the lengths of its components through the Pythagorean theorem.



Suppose that $\vec{A}$ is equal to zero. Then $A^2 = A_x^2 + A_y^2 = 0$.

But $A_x^2 + A_y^2 = 0 \Rightarrow A_x = A_y = 0$.

No. If a vector is equal to zero, each of its components must be zero too.

7 •

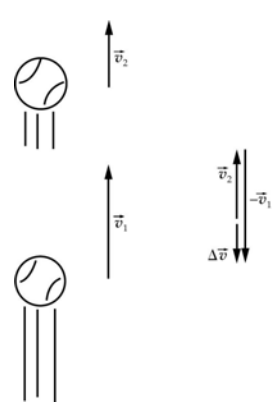
Determine the Concept No. Consider the special case in which $\vec{B} = -\vec{A}$. If $\vec{B} = -\vec{A} \ne 0$, then $\vec{C} = 0$ and the magnitudes of the components of $\vec{A}$ and $\vec{B}$ are larger than the components of $\vec{C}$.

***8** •

Determine the Concept The *instantaneous acceleration* is the limiting value, as Δt approaches zero, of $\Delta\vec{v}/\Delta t$. Thus, the acceleration vector is in the same direction as $\Delta\vec{v}$.

False. Consider a ball that has been thrown upward near the surface of the earth and is slowing down. *The direction of its motion is upward.*

The diagram shows the ball's velocity vectors at two instants of time and the determination of $\Delta\vec{v}$. Note that because $\Delta\vec{v}$ is downward so is the *acceleration* of the ball.



9 •

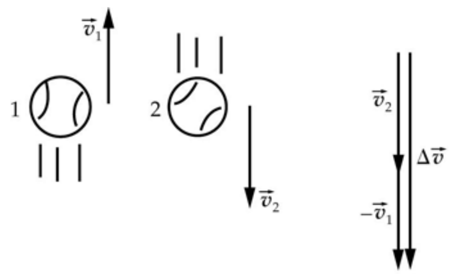
Determine the Concept The *instantaneous acceleration* is the limiting value, as Δt approaches zero, of $\Delta\vec{v}/\Delta t$ and is in the same direction as $\Delta\vec{v}$.

Other than through the definition of $\vec{a}$, the instantaneous velocity and acceleration vectors are unrelated. Knowing the direction of the velocity at one instant tells one nothing about how the velocity is changing at that instant. $\boxed{(e)\text{ is correct.}}$

10 •

Determine the Concept The changing velocity of the golf ball during its flight can be understood by recognizing that it has both horizontal and vertical components. The nature of its acceleration near the highest point of its flight can be understood by analyzing the vertical components of its velocity on either side of this point.

At the highest point of its flight, the ball is still *traveling horizontally* even though its vertical velocity is momentarily zero. The figure to the right shows the vertical components of the ball's velocity just before and just after it has reached its highest point. The change in velocity during this short interval is a non-zero, downward-pointing vector. Because the acceleration is proportional to the change in velocity, it must also be nonzero.



$\boxed{(d)\text{ is correct.}}$

Remarks: Note that v_x is nonzero and v_y is zero, while a_x is zero and a_y is nonzero.

11 •

Determine the Concept The change in the velocity is in the same direction as the acceleration. Choose an *x-y* coordinate system with east being the positive *x* direction and north the positive *y* direction.

Given our choice of coordinate system, the *x* component of $\vec{a}$ is negative and so $\vec{v}$ will decrease. The *y* component of $\vec{a}$ is positive and so $\vec{v}$ will increase toward the north.

$\boxed{(c)\text{ is correct.}}$

***12** •

Determine the Concept The average velocity of a particle, $\vec{v}_{\text{av}}$, is the ratio of the particle's displacement to the time required for the displacement.

(*a*) We can calculate $\Delta\vec{r}$ from the given information and Δt is known. $\boxed{(a)\text{ is correct.}}$

(*b*) We do not have enough information to calculate $\Delta\vec{v}$ and cannot compute the particle's average acceleration.

(*c*) We would need to know how the particle's velocity varies with time in order to compute its instantaneous velocity.

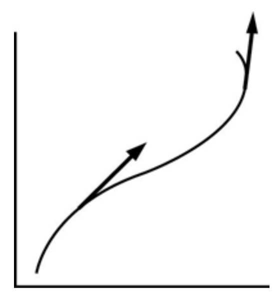
(*d*) We would need to know how the particle's velocity varies with time in order to compute its instantaneous acceleration.

13 ••

Determine the Concept The velocity vector is always in the direction of motion and, thus, tangent to the path.

(*a*) The velocity vector, as a consequence of always being in the direction of motion, is tangent to the path.

(*b*) A sketch showing two velocity vectors for a particle moving along a path is shown to the right.



14 •

Determine the Concept An object experiences acceleration whenever either its speed changes or it changes direction.

The acceleration of a car moving in a straight path at constant speed is zero. In the other examples, either the magnitude or the direction of the velocity vector is changing and, hence, the car is accelerated. (*b*) is correct.

***15** •

Determine the Concept The velocity vector is defined by $\vec{v} = d\vec{r}/dt$, while the acceleration vector is defined by $\vec{a} = d\vec{v}/dt$.

(*a*) A car moving along a straight road while braking.

(*b*) A car moving along a straight road while speeding up.

(*c*) A particle moving around a circular track at constant speed.

16 •

Determine the Concept A particle experiences accelerated motion when either its speed or direction of motion changes.

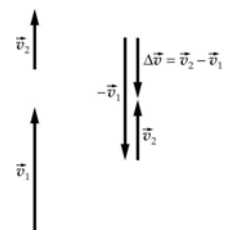
A particle moving at constant speed in a circular path is accelerating because the direction of its velocity vector is changing.

If a particle is moving at constant velocity, it is not accelerating.

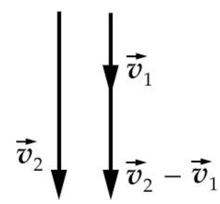
17 ••

Determine the Concept The acceleration vector is in the same direction as the *change in velocity vector,* $\Delta\vec{v}$.

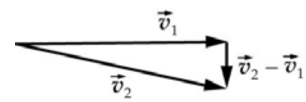
(*a*) The sketch for the dart thrown upward is shown to the right. The acceleration vector is in the direction of the *change* in the velocity vector $\Delta\vec{v}$.



(*b*) The sketch for the falling dart is shown to the right. Again, the acceleration vector is in the direction of the *change* in the velocity vector $\Delta\vec{v}$.



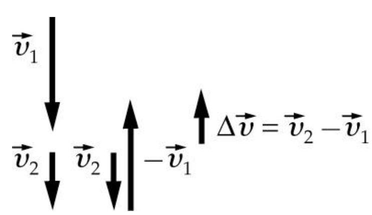
(*c*) The acceleration vector is in the direction of the *change* in the velocity vector … and hence is downward as shown the right:



***18** ••

Determine the Concept The acceleration vector is in the same direction as the *change in velocity vector*, $\Delta\vec{v}$.

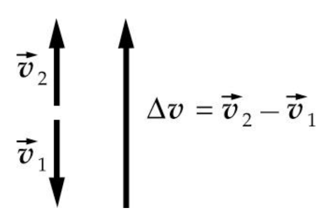
The drawing is shown to the right.



19 ••

Determine the Concept The acceleration vector is in the same direction as the *change in velocity vector,* $\Delta\vec{v}$.

The sketch is shown to the right.



20 •

Determine the Concept We can decide what the pilot should do by considering the speeds of the boat and of the current.

Give up. The speed of the stream is equal to the maximum speed of the boat in still water. The best the boat can do is, while facing directly upstream, maintain its position relative to the bank. $\boxed{(d)\text{ is correct.}}$

***21** •

Determine the Concept True. In the absence of air resistance, both projectiles experience the same downward acceleration. Because both projectiles have initial vertical velocities of zero, their vertical motions must be identical.

22 •

Determine the Concept In the absence of air resistance, the horizontal component of the projectile's velocity is constant for the duration of its flight.

At the highest point, the speed is the horizontal component of the initial velocity. The vertical component is zero at the highest point. $\boxed{(e)\text{ is correct.}}$

23 •

Determine the Concept In the absence of air resistance, the acceleration of the ball depends only on the *change in its velocity* and is independent of its velocity.

As the ball moves along its trajectory between points A and C, the vertical component of its velocity decreases and the *change* in its velocity is a downward pointing vector. Between points C and E, the vertical component of its velocity increases and the *change* in its velocity is also a downward pointing vector. There is no change in the horizontal component of the velocity. $\boxed{(d)\text{ is correct.}}$

24 •

Determine the Concept In the absence of air resistance, the horizontal component of the velocity remains constant throughout the flight. The vertical component has its maximum values at launch and impact.

(*a*) The speed is greatest at A and E.

(*b*) The speed is least at point C.

(*c*) The speed is the same at A and E. The horizontal components are equal at these points but the vertical components are oppositely directed.

25 •

Determine the Concept Speed is a scalar quantity, whereas acceleration, equal to the *rate of change* of velocity, is a vector quantity.

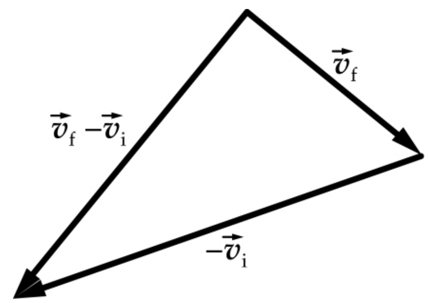
(*a*) False. Consider a ball on the end of a string. The ball can move with constant *speed* (a scalar) even though its *acceleration* (a vector) is always changing direction.

(*b*) True. From its definition, if the acceleration is zero, the velocity must be constant and so, therefore, must be the speed.

26 •

Determine the Concept The average acceleration vector is defined by $\vec{a}_{av} = \Delta\vec{v}/\Delta t$.

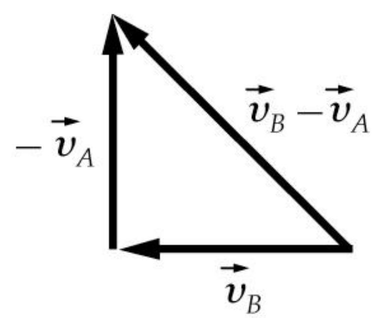
The direction of $\vec{a}_{av}$ is that of $\Delta\vec{v} = \vec{v}_f - \vec{v}_i$, as shown to the right.



27 •

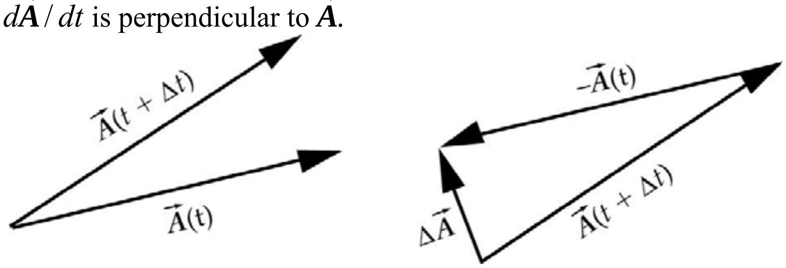
Determine the Concept The velocity of B relative to A is $\vec{v}_{BA} = \vec{v}_B - \vec{v}_A$.

The direction of $\vec{v}_{BA} = \vec{v}_B - \vec{v}_A$ is shown to the right.



***28 ••**

(*a*) The vectors $\vec{A}(t)$ and $\vec{A}(t+\Delta t)$ are of equal length but point in slightly different directions. $\Delta\vec{A}$ is shown in the diagram below. Note that $\Delta\vec{A}$ is nearly perpendicular to $\vec{A}(t)$. For very small time intervals, $\Delta\vec{A}$ and $\vec{A}(t)$ are perpendicular to one another. Therefore, $d\vec{A}/dt$ is perpendicular to $\vec{A}$.



(*b*) If $\vec{A}$ represents the position of a particle, the particle must be undergoing circular motion (i.e., it is at a constant distance from some origin). The velocity vector is tangent to the particle's trajectory; in the case of a circle, it is perpendicular to the circle's radius.

(*c*) Yes, it could in the case of uniform circular motion. The speed of the particle is constant, but its heading is changing constantly. The acceleration vector in this case is always perpendicular to the velocity vector.

29 ••

Determine the Concept The velocity vector is in the same direction as *the change in the position vector* while the acceleration vector is in the same direction as *the change in the velocity vector*. Choose a coordinate system in which the y direction is north and the x direction is east.

(*a*)

Path	Direction of velocity vector
AB	north
BC	northeast
CD	east
DE	southeast
EF	south

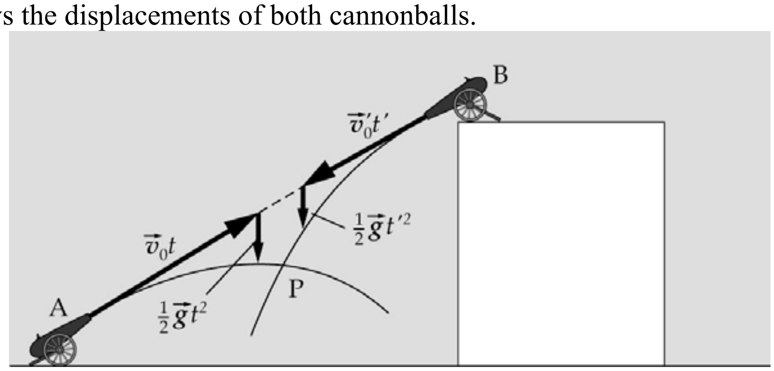
(*b*)

Path	Direction of acceleration vector
AB	north
BC	southeast
CD	0
DE	southwest
EF	north

(*c*) The magnitudes are comparable, but larger for DE since the radius of the path is smaller there.

***30** ••

Determine the Concept We'll assume that the cannons are identical and use a constant-acceleration equation to express the displacement of each cannonball as a function of time. Having done so, we can then establish the condition under which they will have the same vertical position at a given time and, hence, collide. The modified diagram shown below shows the displacements of both cannonballs.



Express the displacement of the cannonball from cannon A at any time t after being fired and before any collision:

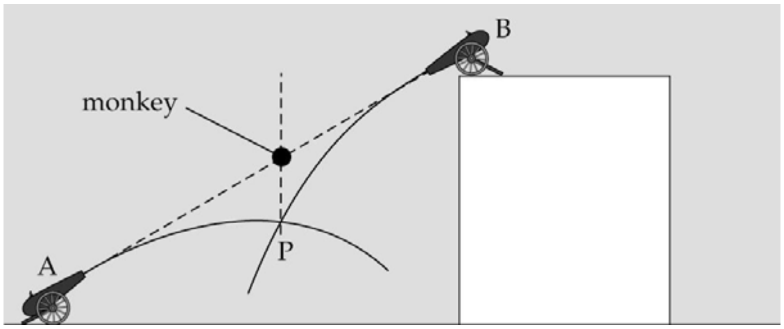
$$\Delta\vec{r} = \vec{v}_0 t + \tfrac{1}{2}\vec{g}t^2$$

Express the displacement of the cannonball from cannon A at any time t' after being fired and before any collision:

$$\Delta\vec{r}' = \vec{v}_0' t' + \tfrac{1}{2}\vec{g}t'^2$$

If the guns are fired simultaneously, $t = t'$ and the balls are the same distance $\frac{1}{2}gt^2$ below the line of sight at all times. Therefore, they should fire the guns simultaneously.

Remarks: This is the "monkey and hunter" problem in disguise. If you imagine a monkey in the position shown below, and the two guns are fired simultaneously, and the monkey begins to fall when the guns are fired, then the monkey and the two cannonballs will all reach point P at the same time.



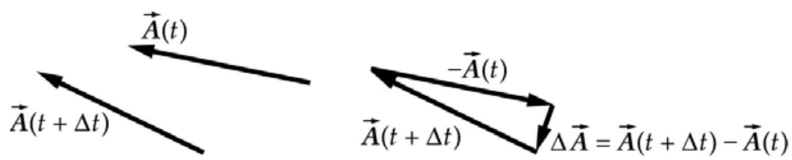
31 ••

Determine the Concept The droplet leaving the bottle has the same horizontal velocity as the ship. During the time the droplet is in the air, it is also moving horizontally with the same velocity as the rest of the ship. Because of this, it falls into the vessel, which has the same horizontal velocity. Because you have the same horizontal velocity as the ship does, you see the same thing as if the ship were standing still.

32 •

Determine the Concept

(*a*) Because $\vec{A}$ and $\vec{D}$ are tangent to the path of the stone, either of them could represent the velocity of the stone.



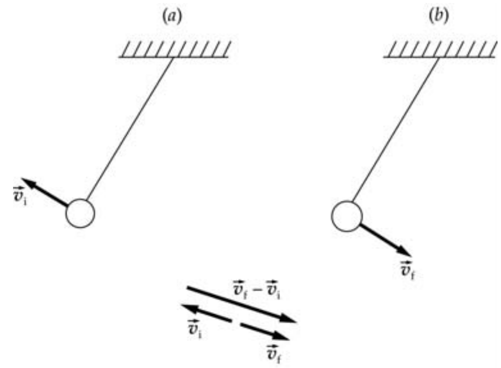
(*b*) Let the vectors $\vec{A}(t)$ and $\vec{B}(t+\Delta t)$ be of equal length but point in slightly different directions as the stone moves around the circle. These two vectors and $\Delta\vec{A}$ are shown in the diagram above. Note that $\Delta\vec{A}$ is nearly perpendicular to $\vec{A}(t)$. For very small time intervals, $\Delta\vec{A}$ and $\vec{A}(t)$ are perpendicular to one another. Therefore, $d\vec{A}/dt$ is perpendicular to $\vec{A}$ and only the vector $\vec{E}$ could represent the acceleration of the stone.

33 •

Determine the Concept True. An object accelerates when its velocity changes; that is, when either its speed or its direction changes. When an object moves in a circle the direction of its motion is continually changing.

34 ••

Picture the Problem In the diagram, (*a*) shows the pendulum just before it reverses direction and (*b*) shows the pendulum just after it has reversed its direction. The acceleration of the bob is in the direction of the *change* in the velocity $\Delta\vec{v} = \vec{v}_f - \vec{v}_i$ and is tangent to the pendulum trajectory at the point of reversal of direction. This makes sense because, at an extremum of motion, $v = 0$, so there is no centripetal acceleration. However, because the velocity is reversing direction, the tangential acceleration is nonzero.



35 •

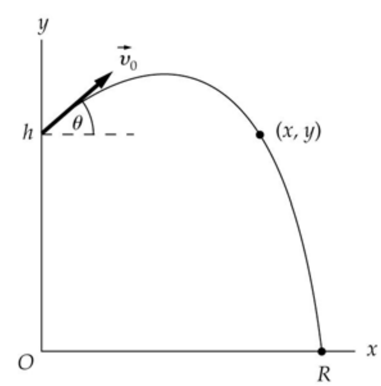
Determine the Concept The principle reason is aerodynamic drag. When moving through a fluid, such as the atmosphere, the ball's acceleration will depend strongly on its velocity.

Estimation and Approximation

***36** ••

Picture the Problem During the flight of the ball the acceleration is constant and equal to 9.81 m/s^2 directed downward. We can find the flight time from the vertical part of the motion, and then use the horizontal part of the motion to find the horizontal distance. We'll assume that the release point of the ball is 2 m above your feet.

Make a sketch of the motion. Include coordinate axes, initial and final positions, and initial velocity components:



Obviously, how far you throw the ball will depend on how fast you can throw it. A major league baseball pitcher can throw a fastball at 90 mi/h or so. Assume that you can throw a ball at two-thirds that speed to obtain:

$$v_0 = 60\,\text{mi/h} \times \frac{0.447\,\text{m/s}}{1\,\text{mi/h}} = 26.8\,\text{m/s}$$

There is no acceleration in the x direction, so the horizontal motion is one of constant velocity. Express the horizontal position of the ball as a function of time:

$$x = v_{0x}t \qquad (1)$$

Assuming that the release point of the ball is a distance h above the ground, express the vertical position of the ball as a function of time:

$$y = h + v_{0y}t + \tfrac{1}{2}a_y t^2 \qquad (2)$$

(a) For $\theta = 0$ we have:

$$v_{0x} = v_0 \cos\theta_0 = (26.8\,\text{m/s})\cos 0° = 26.8\,\text{m/s}$$

and

$$v_{0y} = v_0 \sin\theta_0 = (26.8\,\text{m/s})\sin 0° = 0$$

Substitute in equations (1) and (2) to obtain:

$$x = (26.8\,\text{m/s})t$$

and

$$y = 2\,\text{m} + \tfrac{1}{2}\left(-9.81\,\text{m/s}^2\right)t^2$$

Eliminate t between these equations to obtain:

$$y = 2\,\text{m} - \frac{4.91\,\text{m/s}^2}{(26.8\,\text{m/s})^2}x^2$$

At impact, $y = 0$ and $x = R$:

$$0 = 2\,\text{m} - \frac{4.91\,\text{m/s}^2}{(26.8\,\text{m/s})^2}R^2$$

Solve for R to obtain:

$$R = \boxed{17.1\,\text{m}}$$

(b) Using trigonometry, solve for v_{0x} and v_{0y}:

$$v_{0x} = v_0 \cos\theta_0 = (26.8\,\text{m/s})\cos 45° = 19.0\,\text{m/s}$$

and

$$v_{0y} = v_0 \sin\theta_0 = (26.8\,\text{m/s})\sin 45° = 19.0\,\text{m/s}$$

Substitute in equations (1) and (2) to obtain:

$$x = (19.0\,\text{m/s})t$$

and

$$y = 2\,\text{m} + (19.0\,\text{m/s})t + \tfrac{1}{2}\left(-9.81\,\text{m/s}^2\right)t^2$$

Eliminate t between these equations to obtain:

$$y = 2\,\text{m} + x - \frac{4.905\,\text{m/s}^2}{(19.0\,\text{m/s})^2}x^2$$

At impact, $y = 0$ and $x = R$. Hence:

$$0 = 2\,\text{m} + R - \frac{4.905\,\text{m/s}^2}{(19.0\,\text{m/s})^2}R^2$$

or

$$R^2 - (73.60\,\text{m})R - 147.2\,\text{m}^2 = 0$$

Solve for R (you can use the ″solver″ or ″graph″ functions of your calculator) to obtain:

$$R = \boxed{75.6\,\text{m}}$$

(c) Solve for v_{0x} and v_{0y}:

$$v_{0x} = v_0 = 26.8\,\text{m/s}$$

and

$$v_{0y} = 0$$

Substitute in equations (1) and (2) to obtain:

$$x = (26.8\,\text{m/s})t$$

and

$$y = 14\,\text{m} + \tfrac{1}{2}\left(-9.81\,\text{m/s}^2\right)t^2$$

Eliminate t between these equations to obtain:

$$y = 14\,\text{m} - \frac{4.905\,\text{m/s}^2}{(26.8\,\text{m/s})^2}x^2$$

At impact, $y = 0$ and $x = R$:

$$0 = 14\,\text{m} - \frac{4.905\,\text{m/s}^2}{(26.8\,\text{m/s})^2}R^2$$

Solve for R to obtain:

$$R = \boxed{45.3\,\text{m}}$$

(d) Using trigonometry, solve for v_{0x} and v_{0y}:

$$v_{0x} = v_{0y} = 19.0\text{ m / s}$$

Substitute in equations (1) and (2) to obtain:

$$x = (19.0\,\text{m/s})t$$

and

$$y = 14\,\text{m} + (19.0\,\text{m/s})t + \tfrac{1}{2}\left(-9.81\,\text{m/s}^2\right)t^2$$

Eliminate t between these equations to obtain:

$$y = 14\,\text{m} + x - \frac{4.905\,\text{m/s}^2}{(19.0\,\text{m/s})^2}x^2$$

At impact, $y = 0$ and $x = R$:

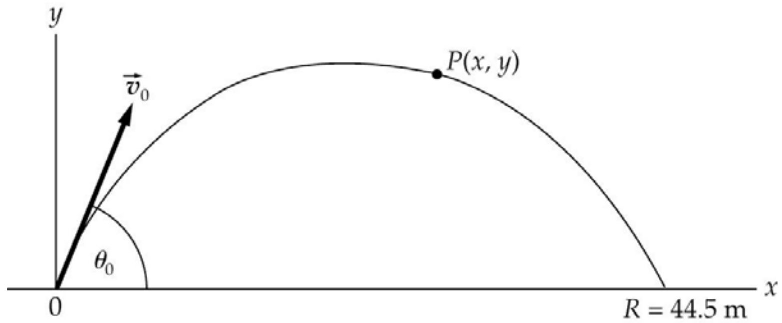
$$0 = 14\,\text{m} + R - \frac{4.905\,\text{m/s}^2}{(19.0\,\text{m/s})^2}R^2$$

Solve for R (you can use the ″solver″ or ″graph″ function of your calculator) to obtain:

$$R = \boxed{85.6\,\text{m}}$$

37 ••

Picture the Problem We'll ignore the height of Geoff's release point above the ground and assume that he launched the brick at an angle of 45°. Because the velocity of the brick at the highest point of its flight is equal to the horizontal component of its initial velocity, we can use constant-acceleration equations to relate this velocity to the brick's x and y coordinates at impact. The diagram shows an appropriate coordinate system and the brick when it is at point P with coordinates (x, y).



Using a constant-acceleration equation, express the x coordinate of the brick as a function of time:

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$

or, because $x_0 = 0$ and $a_x = 0$,

$$x = v_{0x}t$$

Express the y coordinate of the brick as a function of time:

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$

or, because $y_0 = 0$ and $a_y = -g$,

$$y = v_{0y}t - \tfrac{1}{2}gt^2$$

Eliminate the parameter t to obtain:

$$y = (\tan\theta_0)x - \frac{g}{2v_{0x}^2}x^2$$

Use the brick's coordinates when it strikes the ground to obtain:

$$0 = (\tan\theta_0)R - \frac{g}{2v_{0x}^2}R^2$$

where R is the range of the brick.

Solve for v_{0x} to obtain:

$$v_{0x} = \sqrt{\frac{gR}{2\tan\theta_0}}$$

Substitute numerical values and evaluate v_{0x}:

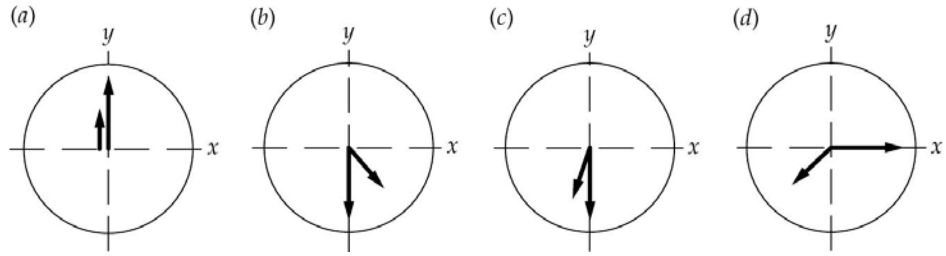
$$v_{0x} = \sqrt{\frac{(9.81\,\text{m/s}^2)(44.5\,\text{m})}{2\tan 45°}} = \boxed{14.8\,\text{m/s}}$$

Note that, at the brick's highest point, $v_y = 0$.

Vectors, Vector Addition, and Coordinate Systems

38 •

Picture the Problem Let the positive y direction be straight up, the positive x direction be to the right, and $\vec{A}$ and $\vec{B}$ be the position vectors for the minute and hour hands. The pictorial representation below shows the orientation of the hands of the clock for parts (*a*) through (*d*).



(*a*) The position vector for the minute hand at12:00 is:

$$\vec{A}_{12:00} = \boxed{(0.5\,\text{m})\hat{\boldsymbol{j}}}$$

The position vector for the hour hand at 12:00 is:

$$\vec{B}_{12:00} = \boxed{(0.25\,\text{m})\hat{\boldsymbol{j}}}$$

(*b*) At 3:30, the minute hand is positioned along the –*y* axis, while the hour hand is at an angle of (3.5 h)/12 h × 360° = 105°, measured clockwise from the top.

The position vector for the minute hand is:

$$\vec{A}_{3:30} = \boxed{-(0.5\,\text{m})\hat{\boldsymbol{j}}}$$

Find the *x*-component of the vector representing the hour hand:

$$B_x = (0.25\,\text{m})\sin 105° = 0.241\,\text{m}$$

Find the *y*-component of the vector representing the hour hand:

$$B_y = (0.25\,\text{m})\cos 105° = -0.0647\,\text{m}$$

The position vector for the hour hand is:

$$\vec{B}_{3:30} = \boxed{(0.241\,\text{m})\hat{\boldsymbol{i}} - (0.0647\,\text{m})\hat{\boldsymbol{j}}}$$

(*c*) At 6:30, the minute hand is positioned along the –*y* axis, while the hour hand is at an angle of (6.5 h)/12 h × 360° = 195°, measured clockwise from the top.

The position vector for the minute hand is:

$$\vec{A}_{6:30} = \boxed{-(0.5\,\text{m})\hat{\boldsymbol{j}}}$$

Find the *x*-component of the vector representing the hour hand:

$$B_x = (0.25\,\text{m})\sin 195° = -0.0647\,\text{m}$$

Find the *y*-component of the vector representing the hour hand:

$$B_y = (0.25\,\text{m})\cos 195° = -0.241\,\text{m}$$

The position vector for the hour hand is:

$$\vec{B}_{6:30} = \boxed{-(0.0647\,\text{m})\hat{\boldsymbol{i}} - (0.241\,\text{m})\hat{\boldsymbol{j}}}$$

(*d*) At 7:15, the minute hand is positioned along the +*x* axis, while the hour hand is at an angle of (7.25 h)/12 h × 360° = 218°, measured clockwise from the top.

The position vector for the minute hand is:

$$\vec{A}_{7:15} = \boxed{(0.5\,\text{m})\hat{i}}$$

Find the x-component of the vector representing the hour hand:

$$B_x = (0.25\,\text{m})\sin 218° = -0.154\,\text{m}$$

Find the y-component of the vector representing the hour hand:

$$B_y = (0.25\,\text{m})\cos 218° = -0.197\,\text{m}$$

The position vector for the hour hand is:

$$\vec{B}_{7:15} = \boxed{-(0.154\,\text{m})\hat{i} - (0.197\,\text{m})\hat{j}}$$

(e) Find $\vec{A} - \vec{B}$ at 12:00:

$$\vec{A} - \vec{B} = (0.5\,\text{m})\hat{j} - (0.25\,\text{m})\hat{j} = \boxed{(0.25\,\text{m})\hat{j}}$$

Find $\vec{A} - \vec{B}$ at 3:30:

$$\vec{A} - \vec{B} = -(0.5\,\text{m})\hat{j} - \left[(0.241\,\text{m})\hat{i} - (0.0647\,\text{m})\hat{j}\right] = \boxed{-(0.241\,\text{m})\hat{i} - (0.435\,\text{m})\hat{j}}$$

Find $\vec{A} - \vec{B}$ at 6:30:

$$\vec{A} - \vec{B} = -(0.5\,\text{m})\hat{j} - \left[(0.0647\,\text{m})\hat{i} - (0.241\,\text{m})\hat{j}\right] = \boxed{-(0.0647\,\text{m})\hat{i} - (0.259\,\text{m})\hat{j}}$$

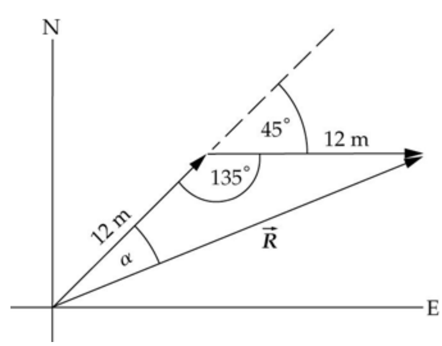
Find $\vec{A} - \vec{B}$ at 7:15:

$$\vec{A} - \vec{B} = (0.5\,\text{m})\hat{j} - \left[-(0.152\,\text{m})\hat{i} - (0.197\,\text{m})\hat{j}\right] = \boxed{(0.152\,\text{m})\hat{i} + (0.697\,\text{m})\hat{j}}$$

***39** •

Picture the Problem The resultant displacement is the vector sum of the individual displacements.

The two displacements of the bear and its resultant displacement are shown to the right:



Using the law of cosines, solve for the resultant displacement:

$$R^2 = (12\,\text{m})^2 + (12\,\text{m})^2 - 2(12\,\text{m})(12\,\text{m})\cos 135°$$

and

$$R = \boxed{22.2\,\text{m}}$$

Using the law of sines, solve for α:

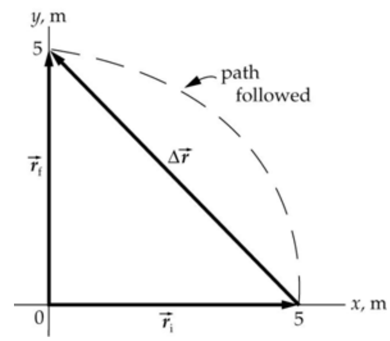
$$\frac{\sin\alpha}{12\,\text{m}} = \frac{\sin 135°}{22.2\,\text{m}}$$

$\therefore$ α = 22.5° and the angle with the horizontal is 45° – 22.5° = $\boxed{22.5°}$

40 •

Picture the Problem The resultant displacement is the vector sum of the individual displacements.

(*a*) Using the endpoint coordinates for her initial and final positions, draw the student's initial and final position vectors and construct her displacement vector.



Find the magnitude of her displacement and the angle this displacement makes with the positive *x*-axis:

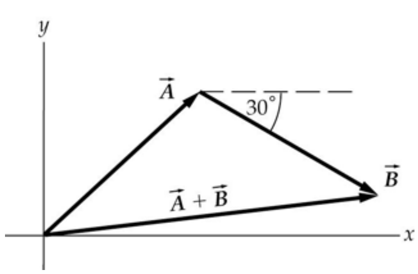
$\boxed{\text{Her displacement is } 5\sqrt{2}\text{ m @ }135°.}$

(*b*) $\boxed{\text{His initial and final positions are the same as in } (a)\text{, so his displacement is also } 5\sqrt{2}\text{ @ }135°.}$

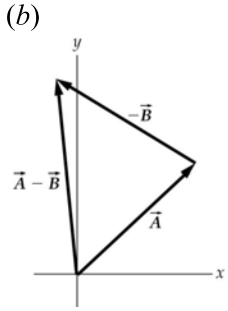
***41** •

Picture the Problem Use the standard rules for vector addition. Remember that changing the sign of a vector reverses its direction.

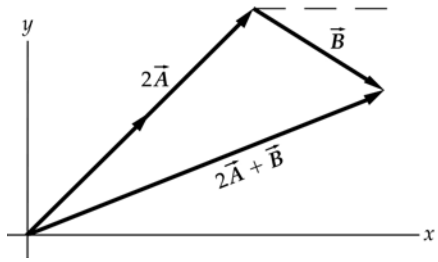
(*a*)



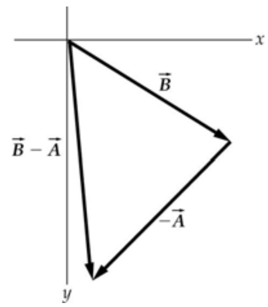
(*b*)



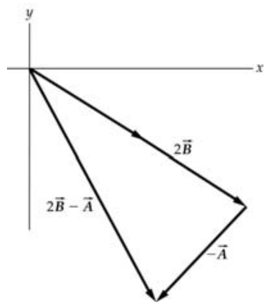
(*c*)



(*d*)

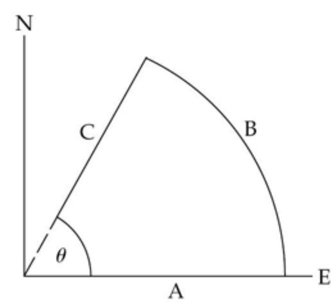


(*e*)



42 •

Picture the Problem The figure shows the paths walked by the Scout. The length of path A is 2.4 km; the length of path B is 2.4 km; and the length of path C is 1.5 km:



(*a*) Express the distance from the campsite to the end of path C:

$$2.4\text{ km} - 1.5\text{ km} = \boxed{0.9\text{ km}}$$

(*b*) Determine the angle θ subtended by the arc at the origin (campsite):

$$\theta_{\text{radians}} = \frac{\text{arc length}}{\text{radius}} = \frac{2.4\text{ km}}{2.4\text{ km}}$$

$$= 1\text{ rad} = 57.3°$$

$$\boxed{\begin{array}{l}\text{His direction from camp}\\ \text{is 1 rad north of east.}\end{array}}$$

(*c*) Express the total distance as the sum of the three parts of his walk:

$$d_{\text{tot}} = d_{\text{east}} + d_{\text{arc}} + d_{\text{toward camp}}$$

Substitute the given distances to find the total:

$$d_{\text{tot}} = 2.4\text{ km} + 2.4\text{ km} + 1.5\text{ km}$$
$$= 6.3\text{ km}$$

Express the ratio of the magnitude of his displacement to the total distance he walked and substitute to obtain a numerical value for this ratio:

$$\frac{\text{Magnitude of his displacement}}{\text{Total distance walked}} = \frac{0.9\,\text{km}}{6.3\,\text{km}} = \boxed{\frac{1}{7}}$$

43 •

Picture the Problem The direction of a vector is determined by its components.

$$\theta = \tan^{-1}\left(\frac{-3.5\,\text{m/s}}{5.5\,\text{m/s}}\right) = -32.5°$$

The vector is in the fourth quadrant and $\boxed{(b)\text{ is correct.}}$

44 •

Picture the Problem The components of the resultant vector can be obtained from the components of the vectors being added. The magnitude of the resultant vector can then be found by using the Pythagorean Theorem.

A table such as the one shown to the right is useful in organizing the information in this problem. Let $\vec{D}$ be the sum of vectors $\vec{A}$, $\vec{B}$, and $\vec{C}$.

Vector	x-component	y-component
$\vec{A}$	6	−3
$\vec{B}$	−3	4
$\vec{C}$	2	5
$\vec{D}$		

Determine the components of $\vec{D}$ by adding the components of $\vec{A}$, $\vec{B}$, and $\vec{C}$.

$D_x = 5$ and $D_y = 6$

Use the Pythagorean Theorem to calculate the magnitude of $\vec{D}$:

$$D = \sqrt{D_x^2 + D_y^2} = \sqrt{(5)^2 + (6)^2} = 7.81$$

and $\boxed{(d)\text{ is correct.}}$

45 •

Picture the Problem The components of the given vector can be determined using right-triangle trigonometry.

Use the trigonometric relationships between the magnitude of a vector and its components to calculate the x- and y-components of each vector.

	A	θ	A_x	A_y
(a)	10 m	30°	8.66 m	5 m
(b)	5 m	45°	3.54 m	3.54 m
(c)	7 km	60°	3.50 km	6.06 km
(d)	5 km	90°	0	5 km

(*e*)	15 km/s	150°	−13.0 km/s	7.50 km/s
(*f*)	10 m/s	240°	−5.00 m/s	−8.66 m/s
(*g*)	8 m/s^2	270°	0	−8.00 m/s^2

***46 •**

Picture the Problem Vectors can be added and subtracted by adding and subtracting their components.

Write $\vec{A}$ in component form:

$A_x = (8\text{ m})\cos 37° = 6.4\text{ m}$

$A_y = (8\text{ m})\sin 37° = 4.8\text{ m}$

$\therefore \vec{A} = (6.4\,\text{m})\hat{i} + (4.8\,\text{m})\hat{j}$

(*a*), (*b*), (*c*) Add (or subtract) *x*- and *y*-components:

$$\vec{D} = \boxed{(0.4\text{m})\hat{i} + (7.8\text{m})\hat{j}}$$

$$\vec{E} = \boxed{(-3.4\text{m})\hat{i} - (9.8\text{m})\hat{j}}$$

$$\vec{F} = \boxed{(-17.6\text{m})\hat{i} + (23.8\text{m})\hat{j}}$$

(*d*) Solve for $\vec{G}$ and add components to obtain:

$$\vec{G} = -\frac{1}{2}\left(\vec{A} + \vec{B} + 2\vec{C}\right)$$

$$= \boxed{(1.3\,\text{m})\hat{i} - (2.9\,\text{m})\hat{j}}$$

47 ••

Picture the Problem The magnitude of each vector can be found from the Pythagorean theorem and their directions found using the inverse tangent function.

(*a*) $\vec{A} = 5\hat{i} + 3\hat{j}$

$$A = \sqrt{A_x^2 + A_y^2} = \boxed{5.83}$$

and, because $\vec{A}$ is in the 1st quadrant,

$$\theta = \tan^{-1}\left(\frac{A_y}{A_x}\right) = \boxed{31.0°}$$

(*b*) $\vec{B} = 10\hat{i} - 7\hat{j}$

$$B = \sqrt{B_x^2 + B_y^2} = \boxed{12.2}$$

and, because $\vec{B}$ is in the 4th quadrant,

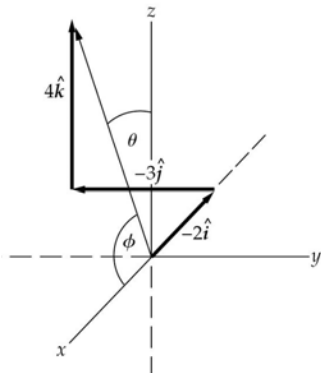
$$\theta = \tan^{-1}\left(\frac{B_y}{B_x}\right) = \boxed{-35.0°}$$

(*c*) $\vec{C} = -2\hat{i} - 3\hat{j} + 4\hat{k}$

$$C = \sqrt{C_x^2 + C_y^2 + C_z^2} = \boxed{5.39}$$

$$\theta = \cos^{-1}\left(\frac{C_z}{C}\right) = \boxed{42.1°}$$

where θ is the polar angle measured from the positive *z*-axis and



$$\phi = \cos^{-1}\left(\frac{C_x}{C}\right) = \cos^{-1}\left(\frac{-2}{\sqrt{29}}\right) = \boxed{112°}$$

48 •

Picture the Problem The magnitude and direction of a two-dimensional vector can be found by using the Pythagorean Theorem and the definition of the tangent function.

(*a*) $\vec{A} = -4\hat{i} - 7\hat{j}$

$$A = \sqrt{A_x^2 + A_y^2} = \boxed{8.06}$$

and, because $\vec{A}$ is in the 3rd quadrant,

$$\theta = \tan^{-1}\left(\frac{A_y}{A_x}\right) = \boxed{240°}$$

$\vec{B} = 3\hat{i} - 2\hat{j}$

$$B = \sqrt{B_x^2 + B_y^2} = \boxed{3.61}$$

and, because $\vec{B}$ is in the 4th quadrant,

$$\theta = \tan^{-1}\left(\frac{B_y}{B_x}\right) = \boxed{-33.7°}$$

$\vec{C} = \vec{A} + \vec{B} = -\hat{i} - 9\hat{j}$

$$C = \sqrt{C_x^2 + C_y^2} = \boxed{9.06}$$

and, because $\vec{C}$ is in the 3rd quadrant,

$$\theta = \tan^{-1}\left(\frac{C_y}{C_x}\right) = \boxed{264°}$$

(*b*) Follow the same steps as in (*a*).

$A = \boxed{4.12}$; $\theta = \boxed{-76.0°}$

$B = \boxed{6.32}$; $\theta = \boxed{71.6°}$

$C = \boxed{3.61}$; $\theta = \boxed{33.7°}$

49 •

Picture the Problem The components of these vectors are related to the magnitude of each vector through the Pythagorean Theorem and trigonometric functions. In parts (*a*) and (*b*), calculate the rectangular components of each vector and then express the vector in rectangular form.

(a) Express $\vec{v}$ in rectangular form:

$$\vec{v} = v_x\hat{i} + v_y\hat{j}$$

Evaluate v_x and v_y:

v_x = (10 m/s) cos 60° = 5 m/s
and
v_y = (10 m/s) sin 60° = 8.66 m/s

Substitute to obtain:

$$\vec{v} = \boxed{(5\,\text{m/s})\hat{i} + (8.66\,\text{m/s})\hat{j}}$$

(b) Express $\vec{v}$ in rectangular form:

$$\vec{A} = A_x\hat{i} + A_y\hat{j}$$

Evaluate A_x and A_y:

A_x = (5 m) cos 225° = –3.54 m
and
A_y = (5 m) sin 225° = –3.54 m

Substitute to obtain:

$$\vec{A} = \boxed{(-3.54\,\text{m})\hat{i} + (-3.54\,\text{m})\hat{j}}$$

(c) There is nothing to calculate as we are given the rectangular components:

$$\vec{r} = \boxed{(14\text{m})\hat{i} - (6\text{m})\hat{j}}$$

50 •

Picture the Problem While there are infinitely many vectors $\vec{B}$ that can be constructed such that $A = B$, the simplest are those which lie along the coordinate axes.

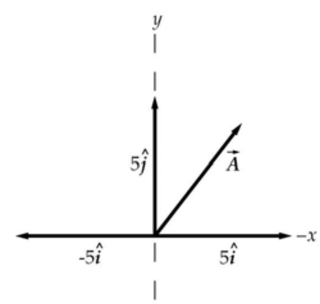
Determine the magnitude of $\vec{A}$:

$$A = \sqrt{A_x^2 + A_y^2} = \sqrt{3^2 + 4^2} = 5$$

Write three vectors of the same magnitude as $\vec{A}$:

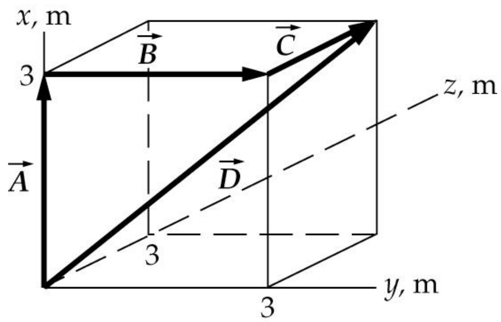
$$\vec{B}_1 = 5\hat{i},\ \vec{B}_2 = -5\hat{i},\ \text{and}\ \vec{B}_3 = 5\hat{j}$$

The vectors are shown to the right:



***51 ••**

Picture the Problem While there are several walking routes the fly could take to get from the origin to point C, its displacement will be the same for all of them. One possible route is shown in the figure.



Express the fly's displacement $\vec{D}$ during its trip from the origin to point C and find its magnitude:

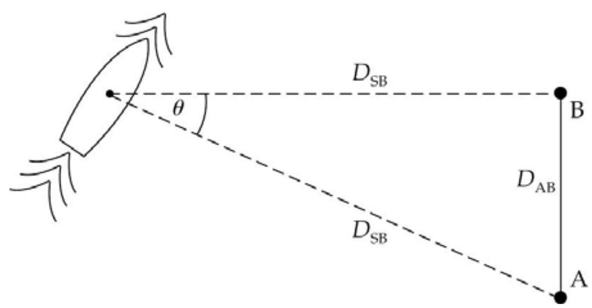
$$\vec{D} = \vec{A} + \vec{B} + \vec{C} = (3\,\text{m})\hat{i} + (3\,\text{m})\hat{j} + (3\,\text{m})\hat{k}$$

and

$$D = \sqrt{(3\,\text{m})^2 + (3\,\text{m})^2 + (3\,\text{m})^2} = \boxed{5.20\,\text{m}}$$

***52 •**

Picture the Problem The diagram shows the locations of the transmitters relative to the ship and defines the distances separating the transmitters from each other and from the ship. We can find the distance between the ship and transmitter B using trigonometry.



Relate the distance between A and B to the distance from the ship to A and the angle θ:

$$\tan\theta = \frac{D_{AB}}{D_{SB}}$$

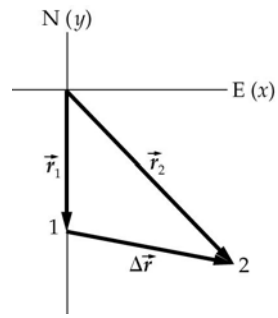
Solve for and evaluate the distance from the ship to transmitter B:

$$D_{SB} = \frac{D_{AB}}{\tan\theta} = \frac{100\,\text{km}}{\tan 30°} = \boxed{173\,\text{km}}$$

Velocity and Acceleration Vectors

53 •

Picture the Problem For constant speed and direction, the instantaneous velocity is identical to the average velocity. Take the origin to be the location of the stationary radar and construct a pictorial representation.



Express the average velocity:

$$\vec{v}_{av} = \frac{\Delta\vec{r}}{\Delta t}$$

Determine the position vectors:

$$\vec{r}_1 = (-10\,\text{km})\hat{j}$$

and

$$\vec{r}_2 = (14.1\,\text{km})\hat{i} + (-14.1\,\text{km})\hat{j}$$

Find the displacement vector:

$$\Delta\vec{r} = \vec{r}_2 - \vec{r}_1 = (14.1\,\text{km})\hat{i} + (-4.1\,\text{km})\hat{j}$$

Substitute for $\Delta\vec{r}$ and Δt to find the average velocity.

$$\vec{v}_{av} = \frac{(14.1\,\text{km})\hat{i} + (-4.1\,\text{km})\hat{j}}{1\,\text{h}} = \boxed{(14.1\,\text{km/h})\hat{i} + (-4.1\,\text{km/h})\hat{j}}$$

54 •

Picture the Problem The average velocity is the change in position divided by the elapsed time.

(*a*) The average velocity is:

$$v_{av} = \frac{\Delta r}{\Delta t}$$

Find the position vectors and the displacement vector:

$$\vec{r}_0 = (2\text{m})\hat{i} + (3\text{m})\hat{j}$$

$$\vec{r}_2 = (6\text{m})\hat{i} + (7\text{m})\hat{j}$$

and

$$\Delta\vec{r} = \vec{r}_2 - \vec{r}_1 = (4\,\text{m})\hat{i} + (4\,\text{m})\hat{j}$$

Find the magnitude of the displacement vector for the interval between $t = 0$ and $t = 2$ s:

$$\Delta r_{02} = \sqrt{(4\text{m})^2 + (4\text{m})^2} = 5.66\text{m}$$

Substitute to determine v_{av}:

$$v_{av} = \frac{5.66\text{ m}}{2\text{ s}} = \boxed{2.83\text{ m/s}}$$

and

$$\theta = \tan^{-1}\left(\frac{4\text{ m}}{4\text{ m}}\right) = \boxed{45.0°}\text{ measured}$$

from the positive x axis.

(b) Repeat (a), this time using the displacement between $t = 0$ and $t = 5$ s to obtain:

$$\vec{r}_5 = (13\text{ m})\hat{i} + (14\text{ m})\hat{j},$$

$$\Delta\vec{r}_{05} = \vec{r}_5 - \vec{r}_0 = (11\text{ m})\hat{i} + (11\text{ m})\hat{j},$$

$$\Delta r_{05} = \sqrt{(11\text{ m})^2 + (11\text{ m})^2} = 15.6\text{ m},$$

$$v_{av} = \frac{15.6\text{ m}}{5\text{ s}} = \boxed{3.11\text{ m/s}},$$

and

$$\theta = \tan^{-1}\left(\frac{11\text{ m}}{11\text{ m}}\right) = \boxed{45.0°}\text{ measured}$$

from the positive x axis.

***55 •**

Picture the Problem The magnitude of the velocity vector at the end of the 2 s of acceleration will give us its speed at that instant. This is a constant-acceleration problem.

Find the final velocity vector of the particle:

$$\vec{v} = v_x\hat{i} + v_y\hat{j} = v_{x0}\hat{i} + a_y t\hat{j}$$
$$= (4.0\text{ m/s})\hat{i} + (3.0\text{ m/s}^2)(2.0\text{ s})\hat{j}$$
$$= (4.0\text{ m/s})\hat{i} + (6.0\text{ m/s})\hat{j}$$

Find the magnitude of $\vec{v}$:

$$v = \sqrt{(4.0\text{ m/s})^2 + (6.0\text{ m/s})^2} = 7.21\text{ m/s}$$

and $\boxed{(b)\text{ is correct.}}$

56 •

Picture the Problem Choose a coordinate system in which north coincides with the positive y direction and east with the positive x direction. Expressing the west and north velocity vectors is the first step in determining $\Delta\vec{v}$ and $\vec{a}_{av}$.

(a) The magnitudes of $\vec{v}_W$ and $\vec{v}_N$ are 40 m/s and 30 m/s, respectively. The change in the magnitude of the particle's velocity during this time is:

$$\Delta v = v_N - v_W$$
$$= \boxed{-10\text{ m/s}}$$

(*b*) The change in the direction of the velocity is from west to north.

The change in direction is $\boxed{90°}$

(*c*) The change in velocity is:

$$\Delta\vec{v} = \vec{v}_{\text{N}} - \vec{v}_{\text{W}} = (30\,\text{m/s})\hat{j} - (-40\,\text{m/s})\hat{i}$$
$$= (40\,\text{m/s})\hat{i} + (30\,\text{m/s})\hat{j}$$

Calculate the magnitude and direction of $\Delta\vec{v}$:

$$|\Delta v| = \sqrt{(40\,\text{m/s})^2 + (30\,\text{m/s})^2} = \boxed{50\,\text{m/s}}$$

and

$$\theta_{+x\,\text{axis}} = \tan^{-1}\frac{30\,\text{m/s}}{40\,\text{m/s}} = \boxed{36.9°}$$

(*d*) Find the average acceleration during this interval:

$$\vec{a}_{\text{av}} \equiv \Delta\vec{v}/\Delta t = \frac{(40\,\text{m/s})\hat{i} + (30\,\text{m/s})\hat{j}}{5\,\text{s}}$$
$$= (8\,\text{m/s}^2)\hat{i} + (6\,\text{m/s}^2)\hat{j}$$

The magnitude of this vector is:

$$a_{\text{av}} = \sqrt{(8\,\text{m/s}^2)^2 + (6\,\text{m/s}^2)^2} = \boxed{10\,\text{m/s}^2}$$

and its direction is

$$\theta = \tan^{-1}\left(\frac{6\,\text{m/s}^2}{8\,\text{m/s}^2}\right) = \boxed{36.9°}\ \text{measured}$$

from the positive *x* axis.

57 •

Picture the Problem The initial and final positions and velocities of the particle are given. We can find the average velocity and average acceleration using their definitions by first calculating the given displacement and velocities using unit vectors $\hat{i}$ and $\hat{j}$.

(*a*) The average velocity is:

$$\vec{v}_{\text{av}} \equiv \Delta\vec{r}/\Delta t$$

The displacement of the particle during this interval of time is:

$$\Delta\vec{r} = (100\,\text{m})\hat{i} + (80\,\text{m})\hat{j}$$

Substitute to find the average velocity:

$$\vec{v}_{\text{av}} = \frac{(100\,\text{m})\hat{i} + (80\,\text{m})\hat{j}}{3\,\text{s}}$$
$$= \boxed{(33.3\,\text{m/s})\hat{i} + (26.7\,\text{m/s})\hat{j}}$$

(*b*) The average acceleration is:

$$\vec{a}_{\text{av}} = \Delta\vec{v}/\Delta t$$

Find $\vec{v}_1$, $\vec{v}_2$, and $\Delta\vec{v}$:

$$\vec{v}_1 = (28.3\,\text{m/s})\hat{i} + (28.3\,\text{m/s})\hat{j}$$

and

$$\vec{v}_2 = (19.3\,\text{m/s})\hat{i} + (23.0\,\text{m/s})\hat{j}$$

$$\therefore\ \Delta\vec{v} = (-9.00\,\text{m/s})\hat{i} + (-5.30\,\text{m/s})\hat{j}$$

Using $\Delta t = 3$ s, find the average acceleration:

$$\vec{a}_{\text{av}} = \boxed{(-3.00\,\text{m/s}^2)\hat{i} + (-1.77\,\text{m/s}^2)\hat{j}}$$

***58 ••**

Picture the Problem The acceleration is constant so we can use the constant-acceleration equations in vector form to find the velocity at $t = 2$ s and the position vector at $t = 4$ s.

(*a*) The velocity of the particle, as a function of time, is given by:

$$\vec{v} = \vec{v}_0 + \vec{a}t$$

Substitute to find the velocity at $t = 2$ s:

$$\vec{v} = (2\text{ m/s})\hat{i} + (-9\text{ m/s})\hat{j} + \left[(4\text{ m/s}^2)\hat{i} + (3\text{ m/s}^2)\hat{j}\right](2\text{s})$$

$$= \boxed{(10\text{ m/s})\hat{i} + (-3\text{ m/s})\hat{j}}$$

(*b*) Express the position vector as a function of time:

$$\vec{r} = \vec{r}_0 + \vec{v}_0 t + \tfrac{1}{2}\vec{a}t^2$$

Substitute and simplify:

$$\vec{r} = (4\text{ m})\hat{i} + (3\text{ m})\hat{j} + \left[(2\text{ m/s})\hat{i} + (\text{-}9\text{ m/s})\hat{j}\right](4\text{ s}) + \tfrac{1}{2}\left[(4\text{ m/s}^2)\hat{i} + (3\text{ m/s}^2)\hat{j}\right](4\text{ s})^2$$

$$= \boxed{(44\text{ m})\hat{i} + (-9\text{ m})\hat{j}}$$

Find the magnitude and direction of $\vec{r}$ at $t = 4$ s:

$$r(4\text{ s}) = \sqrt{(44\text{ m})^2 + (-9\text{ m})^2} = \boxed{44.9\text{ m}}$$

and, because $\vec{r}$ is in the 4th quadrant,

$$\theta = \tan^{-1}\left(\frac{-9\text{ m}}{44\text{ m}}\right) = \boxed{-11.6°}$$

59 ••

Picture the Problem The velocity vector is the time-derivative of the position vector and the acceleration vector is the time-derivative of the velocity vector.

Differentiate $\vec{r}$ with respect to time:

$$\vec{v} = \frac{d\vec{r}}{dt} = \frac{d}{dt}\left[(30t)\hat{i} + (40t - 5t^2)\hat{j}\right]$$

$$= \boxed{30\hat{i} + (40 - 10t)\hat{j}}$$

where $\vec{v}$ has units of m/s if t is in seconds.

Differentiate $\vec{v}$ with respect to time:

$$\vec{a} = \frac{d\vec{v}}{dt} = \frac{d}{dt}\left[30\hat{i} + (40 - 10t)\hat{j}\right] = \boxed{\left(-10\,\text{m/s}^2\right)\hat{j}}$$

60 ••

Picture the Problem We can use the constant-acceleration equations in vector form to solve the first part of the problem. In the second part, we can eliminate the parameter t from the constant-acceleration equations and express y as a function of x.

(a) Use $\vec{v} = \vec{v}_0 + \vec{a}t$ with $\vec{v}_0 = 0$ to find $\vec{v}$:

$$\boxed{\vec{v} = \left[\left(6\text{m/s}^2\right)\hat{i} + \left(4\text{m/s}^2\right)\hat{j}\right]t}$$

Use $\vec{r} = \vec{r}_0 + \vec{v}_0 t + \frac{1}{2}\vec{a}t^2$ with $\vec{r}_0 = (10\,\text{m})\hat{i}$ to find $\vec{r}$:

$$\boxed{\vec{r} = \left[(10\text{m}) + \left(3\text{m/s}^2\right)t^2\right]\hat{i} + \left[\left(2\text{m/s}^2\right)t^2\right]\hat{j}}$$

(b) Obtain the x and y components of the path from the vector equation in (a):

$$x = 10\,\text{m} + \left(3\,\text{m/s}^2\right)t^2$$

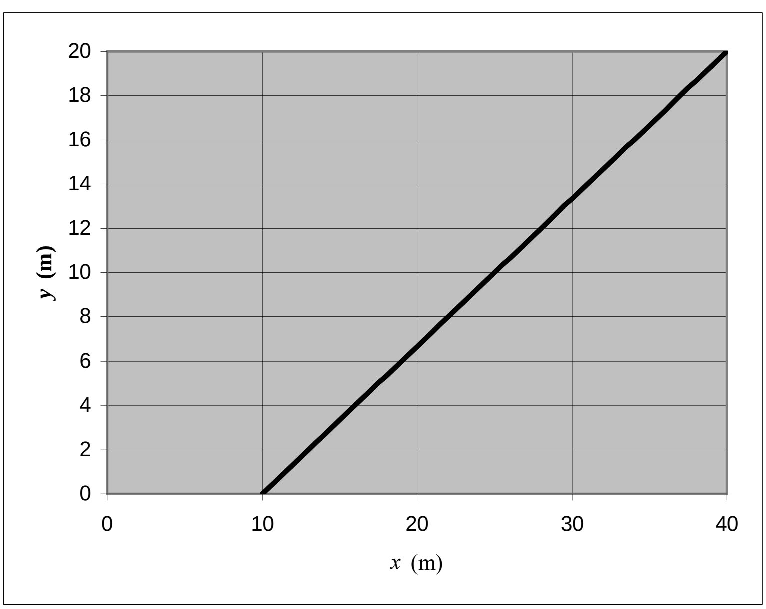
and

$$y = \left(2\,\text{m/s}^2\right)t^2$$

Eliminate the parameter t from these equations and solve for y to obtain:

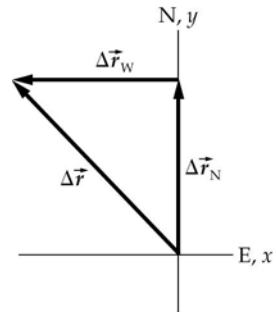
$$\boxed{y = \frac{2}{3}x - \frac{20}{3}\text{m}}$$

Use this equation to plot the graph shown below. Note that the path in the xy plane is a straight line.



61 •••

Picture the Problem The displacements of the boat are shown in the figure. We need to determine each of the displacements in order to calculate the average velocity of the boat during the 30-s trip.



(*a*) Express the average velocity of the boat:

$$\vec{v}_{av} = \frac{\Delta\vec{r}}{\Delta t}$$

Express its total displacement:

$$\Delta\vec{r} = \Delta\vec{r}_N + \Delta\vec{r}_W = \tfrac{1}{2}a_N(\Delta t_N)^2\,\hat{j} + v_W\Delta t_W(-\hat{i})$$

To calculate the displacement we first have to find the speed after the first 20 s:

$$v_W = v_{N,\,f} = a_N\Delta t_N = 60\ \text{m/s}$$

so

$$\Delta\vec{r} = \tfrac{1}{2}a_N(\Delta t_N)^2\,\hat{j} - (60\ \text{m/s})\Delta t_W\hat{i} = (600\text{m})\hat{j} - (600\text{m})\hat{i}$$

Substitute to find the average velocity:

$$\vec{v}_{av} = \frac{\Delta\vec{r}}{\Delta t} = \frac{(600\text{m})(-\hat{i}+\hat{j})}{30\text{s}} = \boxed{(20\text{m/s})(-\hat{i}+\hat{j})}$$

(*b*) The average acceleration is given by:

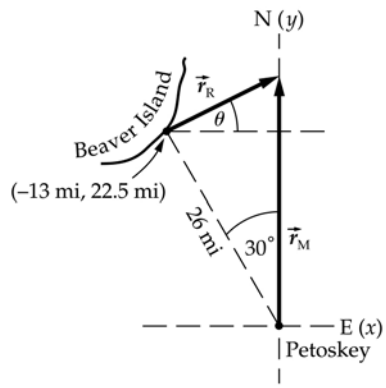
$$\vec{a}_{av} = \frac{\Delta\vec{r}}{\Delta t} = \frac{\vec{v}_f - \vec{v}_i}{\Delta t} = \frac{(-60\ \text{m/s})\hat{i} - 0}{30\ \text{s}} = \boxed{(-2\ \text{m/s}^2)\hat{i}}$$

(*c*) The displacement of the boat from the dock at the end of the 30-s trip was one of the intermediate results we obtained in part (*a*).

$$\Delta\vec{r} = (600\text{m})\hat{j} + (-600\text{m})\hat{i} = \boxed{(600\text{m})(-\hat{i}+\hat{j})}$$

***62** •••

Picture the Problem Choose a coordinate system with the origin at Petoskey, the positive x direction to the east, and the positive y direction to the north. Let $t = 0$ at 9:00 a.m. and θ be the angle between Robert's velocity vector and the easterly direction and let "M" and "R" denote Mary and Robert, respectively. You can express the positions of Mary and Robert as functions of time and then equate their north (y) and east (x) coordinates at the time they rendezvous.



Express Mary's position as a function of time:

$$\vec{r}_M = v_M t\,\hat{j} = (8t)\hat{j}$$

where $\vec{r}_M$ is in miles if t is in hours.

Note that Robert's initial position coordinates (x_i, y_i) are:

$(x_i, y_i) = (-13\text{ mi}, 22.5\text{ mi})$

Express Robert's position as a function of time:

$$\begin{aligned}\vec{r}_R &= [x_i + (v_R\cos\theta)(t-1)]\,\hat{i} + [y_i + (v_R\sin\theta)(t-1)]\,\hat{j}\\ &= [-13 + \{6(t-1)\cos\theta\}]\,\hat{i} + [22.5 + \{6(t-1)\sin\theta\}]\,\hat{j}\end{aligned}$$

where $\vec{r}_R$ is in miles if t is in hours.

When Mary and Robert rendezvous, their coordinates will be the same. Equating their north and east coordinates yields:

East: $-13 + 6t\cos\theta - 6\cos\theta = 0$ (1)

North: $22.5 + 6t\sin\theta - 6\sin\theta = 8t$ (2)

Solve equation (1) for $\cos\theta$:

$$\cos\theta = \frac{13}{6(t-1)} \tag{3}$$

Solve equation (2) for $\sin\theta$:

$$\sin\theta = \frac{8t - 22.5}{6(t-1)} \tag{4}$$

Square and add equations (3) and (4) to obtain:

$$\sin^2\theta + \cos^2\theta = 1 = \left[\frac{8t-22.5}{6(t-1)}\right]^2 + \left[\frac{13}{6(t-1)}\right]^2$$

Simplify to obtain a quadratic equation in t:

$$28t^2 - 288t + 639 = 0$$

Solve (you could use your calculator's "solver" function) this

$$t = \boxed{3.24\,\text{h} = 3\,\text{h}\ 15\,\text{min}}$$

equation for the smallest value of t (both roots are positive) to obtain:

Now you can find the distance traveled due north by Mary:

$$r_M = v_M t = (8\,\text{mi/h})(3.24\,\text{h}) = \boxed{25.9\,\text{mi}}$$

Finally, solving equation (3) for θ and substituting 3.24 h for t yields:

$$\theta = \cos^{-1}\left[\frac{13}{6(t-1)}\right] = \cos^{-1}\left[\frac{13}{6(3.24-1)}\right] = 14.7°$$

and so Robert should head $\boxed{14.7° \text{ north of east.}}$

Remarks: Another solution that does not depend on the components of the vectors utilizes the law of cosines to find the time *t* at which Mary and Robert meet and then uses the law of sines to find the direction that Robert must head in order to rendezvous with Mary.

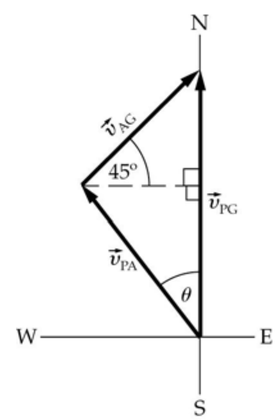
Relative Velocity

63 ••

Picture the Problem Choose a coordinate system in which north is the positive y direction and east is the positive x direction. Let θ be the angle between north and the direction of the plane's heading. The velocity of the plane relative to the ground, $\vec{v}_{PG}$, is the sum of the velocity of the plane relative to the air, $\vec{v}_{PA}$, and the velocity of the air relative to the ground, $\vec{v}_{AG}$. i.e.,

$$\vec{v}_{PG} = \vec{v}_{PA} + \vec{v}_{AG}$$

The pilot must head in such a direction that the east-west component of $\vec{v}_{PG}$ is zero in order to make the plane fly due north.



(*a*) From the diagram one can see that:

$$v_{AG} \cos 45° = v_{PA} \sin\theta$$

Solve for and evaluate θ:

$$\theta = \sin^{-1}\left(\frac{56.6\,\text{km/h}}{250\,\text{km/h}}\right) = \boxed{13.1° \text{ west of north}}$$

(*b*) Because the plane is headed due north, add the north components of

$$\left|\vec{v}_{PG}\right| = (250\text{ km/h}) \cos 13.1° + (80\text{ km/h}) \sin 45°$$

$\vec{v}_{PA}$ and $\vec{v}_{AG}$ to determine the plane's ground speed:

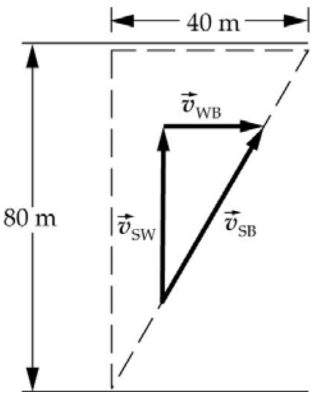
$$= \boxed{300\,\text{km/h}}$$

64 ••

Picture the Problem Let $\vec{v}_{SB}$ represent the velocity of the swimmer relative to the bank; $\vec{v}_{SW}$ the velocity of the swimmer relative to the water; and $\vec{v}_{WB}$ the velocity of the water relative to the shore; i.e.,

$$\vec{v}_{SB} = \vec{v}_{SW} + \vec{v}_{WB}$$

The current of the river causes the swimmer to drift downstream.



(*a*) The triangles shown in the figure are similar right triangles. Set up a proportion between their sides and solve for the speed of the water relative to the bank:

$$\frac{v_{WB}}{v_{SW}} = \frac{40\,\text{m}}{80\,\text{m}}$$

and

$$v_{WB} = \tfrac{1}{2}(1.6\,\text{m/s}) = \boxed{0.800\,\text{m/s}}$$

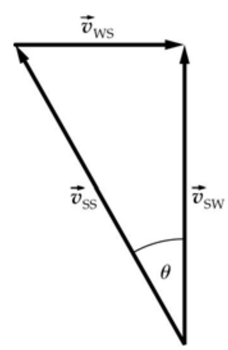
(*b*) Use the Pythagorean Theorem to solve for the swimmer's speed relative to the shore:

$$v_{SB} = \sqrt{v_{SW}^2 + v_{WS}^2}$$

$$= \sqrt{(1.6\,\text{m/s})^2 + (0.8\,\text{m/s})^2}$$

$$= \boxed{1.79\,\text{m/s}}$$

(*c*) The swimmer should head in a direction such that the upstream component of her velocity is equal to the speed of the water relative to the shore:



Use a trigonometric function to evaluate θ:

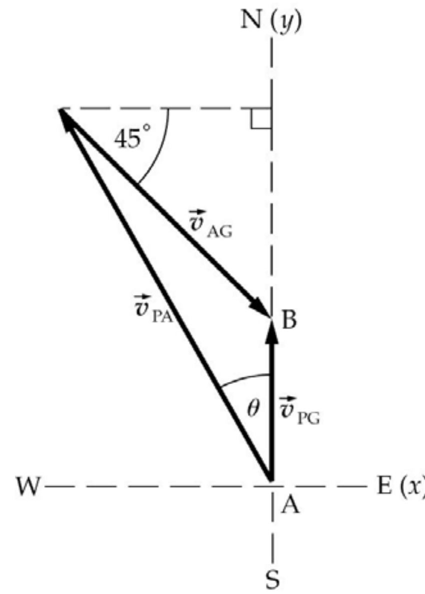
$$\theta = \sin^{-1}\left(\frac{0.8\,\text{m/s}}{1.6\,\text{m/s}}\right) = \boxed{30.0°}$$

***65 ••**

Picture the Problem Let the velocity of the plane relative to the ground be represented by $\vec{v}_{PG}$; the velocity of the plane relative to the air by $\vec{v}_{PA}$, and the velocity of the air relative to the ground by $\vec{v}_{AG}$. Then

$$\vec{v}_{PG} = \vec{v}_{PA} + \vec{v}_{AG} \quad (1)$$

Choose a coordinate system with the origin at point A, the positive x direction to the east, and the positive y direction to the north. θ is the angle between north and the direction of the plane's heading. The pilot must head so that the east-west component of $\vec{v}_{PG}$ is zero in order to make the plane fly due north.



Use the diagram to express the condition relating the eastward component of $\vec{v}_{AG}$ and the westward component of $\vec{v}_{PA}$. This must be satisfied if the plane is to stay on its northerly course. [Note: this is equivalent to equating the x-components of equation (1).]

$$(50 \text{ km/h}) \cos 45° = (240 \text{ km/h}) \sin\theta$$

Now solve for θ to obtain:

$$\theta = \sin^{-1}\left[\frac{(50\,\text{km/h})\cos 45°}{240\,\text{km/h}}\right] = \boxed{8.47°}$$

Add the north components of $\vec{v}_{PA}$ and $\vec{v}_{AG}$ to find the velocity of the plane relative to the ground:

$$v_{PG} + v_{AG}\sin 45° = v_{PA}\cos 8.47°$$

and

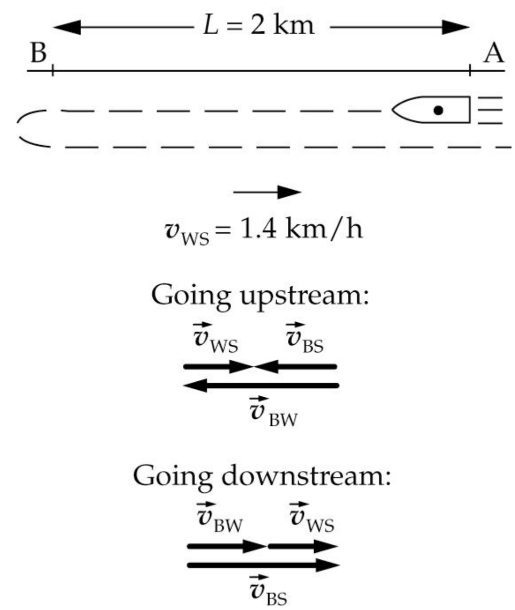
$$\begin{aligned} v_{PG} &= (240 \text{ km/h})\cos 8.47° \\ &\quad - (50 \text{ km/h})\sin 45° \\ &= 202 \text{ km/h} \end{aligned}$$

Finally, find the time of flight:

$$t_{\text{flight}} = \frac{\text{distance travelled}}{v_{PG}} = \frac{520\,\text{km}}{202\,\text{km/h}} = \boxed{2.57\,\text{h}}$$

66 ••

Picture the Problem Let $\vec{v}_{BS}$ be the velocity of the boat relative to the shore; $\vec{v}_{BW}$ be the velocity of the boat relative to the water; and $\vec{v}_{WS}$ represent the velocity of the water relative to the shore. Independently of whether the boat is going upstream or downstream:



$$\vec{v}_{BS} = \vec{v}_{BW} + \vec{v}_{WS}$$

Going upstream, the speed of the boat relative to the shore is reduced by the speed of the water relative to the shore.

Going downstream, the speed of the boat relative to the shore is increased by the same amount.

For the upstream leg of the trip:

$$v_{BS} = v_{BW} - v_{WS}$$

For the downstream leg of the trip:

$$v_{BS} = v_{BW} + v_{WS}$$

Express the total time for the trip in terms of the times for its upstream and downstream legs:

$$t_{total} = t_{upstream} + t_{downstream} = \frac{L}{v_{BW} - v_{WS}} + \frac{L}{v_{BW} + v_{WS}}$$

Multiply both sides of the equation by $(v_{BW} - v_{WS})(v_{BW} + v_{WS})$ (the product of the- denominators) and rearrange the terms to obtain:

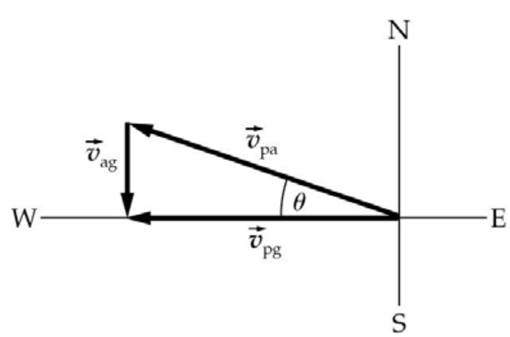
$$v_{BW}^2 - \frac{2L}{t_{total}} v_{BW} - v_{WS}^2 = 0$$

Solve the quadratic equation for v_{BW}. (Only the positive root is physically meaningful.)

$$v_{BW} = \boxed{5.18\,\text{km/h}}$$

67 ••

Picture the Problem Let $\vec{v}_{pg}$ be the velocity of the plane relative to the ground; $\vec{v}_{ag}$ be the velocity of the air relative to the ground; and $\vec{v}_{pa}$ the velocity of the plane relative to the air. Then, $\vec{v}_{pg} = \vec{v}_{pa} + \vec{v}_{ag}$. The wind will affect the flight times differently along these two paths.



The velocity of the plane, relative to the ground, on its eastbound leg is equal to its velocity on its westbound leg. Using the diagram, find the velocity of the plane relative to the ground for both directions:

$$v_{pg} = \sqrt{v_{pa}^2 - v_{ag}^2} = \sqrt{(15\,\text{m/s})^2 - (5\,\text{m/s})^2} = 14.1\,\text{m/s}$$

Express the time for the east-west roundtrip in terms of the distances and velocities for the two legs:

$$t_{\text{roundtrip,EW}} = t_{\text{eastbound}} + t_{\text{westbound}} = \frac{\text{radius of the circle}}{v_{\text{pg,eastbound}}} + \frac{\text{radius of the circle}}{v_{\text{pg,westbound}}} = \frac{2\times10^3\,\text{m}}{14.1\,\text{m/s}} = 141\,\text{s}$$

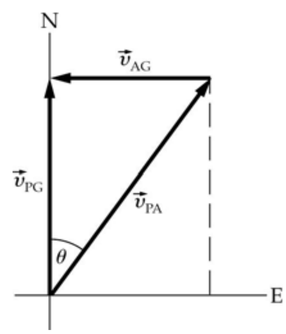
Use the distances and velocities for the two legs to express and evaluate the time for the north-south roundtrip:

$$t_{\text{roundtrip,NS}} = t_{\text{northbound}} + t_{\text{southbound}} = \frac{\text{radius of the circle}}{v_{\text{pg,northbound}}} + \frac{\text{radius of the circle}}{v_{\text{pg,southbound}}} = \frac{10^3\,\text{m}}{(15\,\text{m/s}) - (5\,\text{m/s})} + \frac{10^3\,\text{m}}{(15\,\text{m/s}) + (5\,\text{m/s})} = 150\,\text{s}$$

Because $t_{\text{roundtrip,EW}} < t_{\text{roundtrip,NS}}$, you should fly your plane across the wind.

68 •

Picture the Problem This is a relative velocity problem. The given quantities are the direction of the velocity of the plane relative to the ground and the velocity (magnitude and direction) of the air relative to the ground. Asked for is the direction of the velocity of the air relative to the ground. Using $\vec{v}_{PG} = \vec{v}_{PA} + \vec{v}_{AG}$, draw a vector addition diagram and solve for the unknown quantity.



Calculate the heading the pilot must take:

$$\theta = \sin^{-1}\frac{30\text{ kts}}{150\text{ kts}} = \boxed{11.5°}$$

Because this is also the angle of the plane's heading clockwise from north, it is also its azimuth or the required true heading:

Az = (011.5°)

***69 ••**

Picture the Problem The position of B relative to A is the vector from A to B; i.e.,

$$\vec{r}_{AB} = \vec{r}_B - \vec{r}_A$$

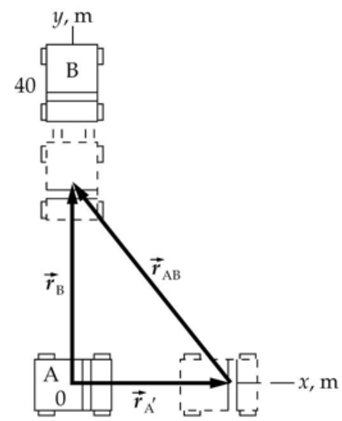
The velocity of B relative to A is

$$\vec{v}_{AB} = d\vec{r}_{AB}/dt$$

and the acceleration of B relative to A is

$$\vec{a}_{AB} = d\vec{v}_{AB}/dt$$

Choose a coordinate system with the origin at the intersection, the positive x direction to the east, and the positive y direction to the north.



(*a*) Find $\vec{r}_B$, $\vec{r}_A$, and $\vec{r}_{AB}$:

$$\vec{r}_B = \left[40\text{m} - \tfrac{1}{2}\left(2\text{m/s}^2\right)t^2\right]\hat{j}$$

$$\vec{r}_A = \left[(20\text{m/s})t\right]\hat{i}$$

and

$$\begin{aligned}\vec{r}_{AB} &= \vec{r}_B - \vec{r}_A \\ &= \left[(-20\text{m/s})t\right]\hat{i} \\ &\quad + \left[40\text{m} - \tfrac{1}{2}\left(2\text{m/s}^2\right)t^2\right]\hat{j}\end{aligned}$$

Evaluate $\vec{r}_{AB}$ at $t = 6$ s:

$$\vec{r}_{AB}(6\text{s}) = \boxed{(120\text{ m})\,\hat{i} + (4\text{ m})\,\hat{j}}$$

(*b*) Find $\vec{v}_{AB} = d\vec{r}_{AB}/dt$:

$$\begin{aligned}\vec{v}_{AB} &= \frac{d\vec{r}_{AB}}{dt} = \frac{d}{dt}\left[\{(-20\text{ m/s})t\}\vec{i}\right. \\ &\quad \left. + \left\{40\text{ m} - \tfrac{1}{2}\left(2\text{ m/s}^2\right)t^2\right\}\hat{j}\right] \\ &= (-20\text{ m/s})\,\hat{i} + (-2\text{ m/s}^2)\,t\,\hat{j}\end{aligned}$$

Evaluate $\vec{v}_{AB}$ at $t = 6$ s:

$$\vec{v}_{AB}(6\text{ s}) = \boxed{(-20\text{ m/s})\hat{i} - (12\text{ m/s})\hat{j}}$$

(*c*) Find $\vec{a}_{AB} = d\vec{v}_{AB}/dt$:

$$\begin{aligned}\vec{a}_{AB} &= \frac{d}{dt}\left[(-20\text{ m/s})\,\hat{i} + (-2\text{ m/s}^2)\,t\,\hat{j}\right] \\ &= \boxed{\left(-2\text{ m/s}^2\right)\hat{j}}\end{aligned}$$

Note that $\vec{a}_{AB}$ is independent of time.

***70 •••**

Picture the Problem Let h and h' represent the heights from which the ball is dropped and to which it rebounds, respectively. Let v and v' represent the speeds with which the ball strikes the racket and rebounds from it. We can use a constant-acceleration equation to relate the pre- and post-collision speeds of the ball to its drop and rebound heights.

(*a*) Using a constant-acceleration equation, relate the impact speed of the ball to the distance it has fallen:

$$v^2 = v_0^2 + 2gh$$

or, because $v_0 = 0$,

$$v = \sqrt{2gh}$$

Relate the rebound speed of the ball to the height to which it rebounds:

$$v^2 = v'^2 - 2gh'$$

or because $v = 0$,

$$v' = \sqrt{2gh'}$$

Divide the second of these equations by the first to obtain:

$$\frac{v'}{v} = \frac{\sqrt{2gh'}}{\sqrt{2gh}} = \sqrt{\frac{h'}{h}}$$

Substitute for h' and evaluate the ratio of the speeds:

$$\frac{v'}{v} = \sqrt{\frac{0.64h}{h}} = 0.8 \Rightarrow v' = \boxed{0.8v}$$

(*b*) Call the speed of the racket V. In a reference frame where the racket is unmoving, the ball initially has speed V, moving *toward* the racket. After it "bounces" from the racket, it will have speed 0.8 V, moving *away* from the racket.

In the reference frame where the racket is moving and the ball initially unmoving, we need to add the speed of the racket to the speed of the ball in the racket's rest frame. Therefore, the ball's speed is:

$$v' = V + 0.8V = 1.8V = 45\,\text{m/s}$$

$$\approx \boxed{100\,\text{mi/h}}$$

This speed is close to that of a tennis pro's serve. Note that this result tells us that the ball is moving significantly faster than the racket.

(*c*) From the result in part (*b*), the ball can never move more than twice as fast as the racket.

Circular Motion and Centripetal Acceleration

71 •

Picture the Problem We can use the definition of centripetal acceleration to express a_c in terms of the speed of the tip of the minute hand. We can find the tangential speed of the tip of the minute hand by using the distance it travels each revolution and the time it takes to complete each revolution.

Express the acceleration of the tip of the minute hand of the clock as a function of the length of the hand and the speed of its tip:

$$a_c = \frac{v^2}{R}$$

Use the distance the minute hand travels every hour to express its speed:

$$v = \frac{2\pi R}{T}$$

Substitute to obtain:

$$a_c = \frac{4\pi^2 R}{T^2}$$

Substitute numerical values and evaluate a_c:

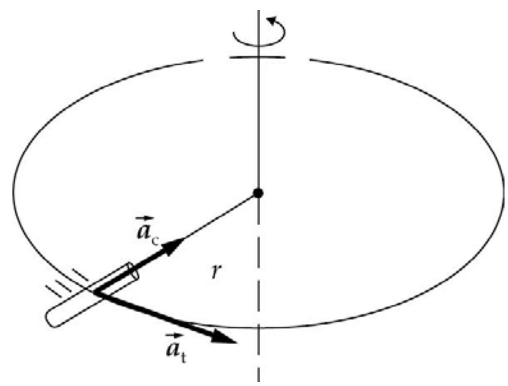
$$a_c = \frac{4\pi^2(0.5\,\text{m})}{(3600\,\text{s})^2} = \boxed{1.52\times10^{-6}\,\text{m/s}^2}$$

Express the ratio of a_c to g:

$$\frac{a_c}{g} = \frac{1.52\times10^{-6}\,\text{m/s}^2}{9.81\,\text{m/s}^2} = \boxed{1.55\times10^{-7}}$$

72 •

Picture the Problem The diagram shows the centripetal and tangential accelerations experienced by the test tube. The tangential acceleration will be zero when the centrifuge reaches its maximum speed. The centripetal acceleration increases as the tangential speed of the centrifuge increases. We can use the definition of centripetal acceleration to express a_c in terms of the speed of the test tube. We can find the tangential speed of the test tube by using the distance it travels each revolution and the time it takes to complete each revolution. The tangential acceleration can be found from the change in the tangential speed as the centrifuge is spinning up.



(*a*) Express the acceleration of the centrifuge arm as a function of the length of its arm and the speed of the test tube:

$$a_c = \frac{v^2}{R}$$

Use the distance the test tube travels every revolution to express its speed:

$$v = \frac{2\pi R}{T}$$

Substitute to obtain:

$$a_c = \frac{4\pi^2 R}{T^2}$$

Substitute numerical values and evaluate a_c:

$$a_c = \frac{4\pi^2(0.15\,\text{m})}{\left(\frac{1\,\text{min}}{15000\,\text{rev}}\times\frac{60\,\text{s}}{\text{min}}\right)^2} = \boxed{3.70\times10^{5}\,\text{m/s}^2}$$

(*b*) Express the tangential acceleration in terms of the difference between the final and initial tangential speeds:

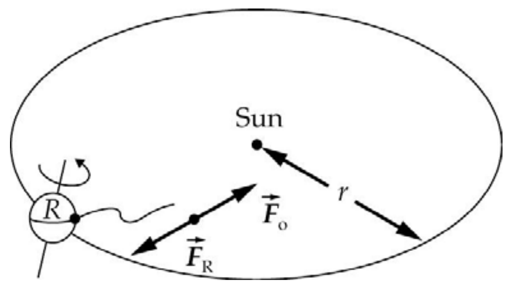
$$a_t = \frac{v_f - v_i}{\Delta t} = \frac{\frac{2\pi R}{T} - 0}{\Delta t} = \frac{2\pi R}{T\Delta t}$$

Substitute numerical values and evaluate a_T:

$$a_t = \frac{2\pi(0.15\,\text{m})}{\left(\frac{1\,\text{min}}{15000\,\text{rev}} \times \frac{60\,\text{s}}{\text{min}}\right)(75\,\text{s})} = \boxed{3.14\,\text{m/s}^2}$$

73 •

Picture the Problem The diagram includes a pictorial representation of the earth in its orbit about the sun and a force diagram showing the force on an object at the equator that is due to the earth's rotation, $\vec{F}_R$, and the force on the object due to the orbital motion of the earth about the sun, $\vec{F}_o$. Because these are centripetal forces, we can calculate the accelerations they require from the speeds and radii associated with the two circular motions.



Express the radial acceleration due to the rotation of the earth:

$$a_R = \frac{v_R^2}{R}$$

Express the speed of the object on the equator in terms of the radius of the earth R and the period of the earth's rotation T_R:

$$v_R = \frac{2\pi R}{T_R}$$

Substitute for v_R in the expression for a_R to obtain:

$$a_R = \frac{4\pi^2 R}{T_R^2}$$

Substitute numerical values and evaluate a_R:

$$a_R = \frac{4\pi^2(6370\times10^3\,\text{m})}{\left[(24\,\text{h})\left(\frac{3600\,\text{s}}{1\,\text{h}}\right)\right]^2} = 3.37\times10^{-2}\,\text{m/s}^2 = \boxed{3.44\times10^{-3}\,g}$$

Note that this effect gives rise to the well-known latitude correction for g.

Express the radial acceleration due to the orbital motion of the earth:

$$a_o = \frac{v_o^2}{r}$$

Express the speed of the object on the equator in terms of the earth-sun distance r and the period of the earth's motion about the sun T_o:

$$v_o = \frac{2\pi r}{T_o}$$

Substitute for v_o in the expression for a_o to obtain:

$$a_o = \frac{4\pi^2 r}{T_o^2}$$

Substitute numerical values and evaluate a_o:

$$a_o = \frac{4\pi^2 (1.5\times10^{11}\text{ m})}{\left[(365\text{ d})\left(\frac{24\text{ h}}{1\text{ d}}\right)\left(\frac{3600\text{ s}}{1\text{ h}}\right)\right]^2}$$

$$= 5.95\times10^{-3}\text{ m/s}^2 = \boxed{6.07\times10^{-4}\,g}$$

74 ••

Picture the Problem We can relate the acceleration of the moon toward the earth to its orbital speed and distance from the earth. Its orbital speed can be expressed in terms of its distance from the earth and its orbital period. From tables of astronomical data, we find that the sidereal period of the moon is 27.3 d and that its mean distance from the earth is 3.84×10^8 m.

Express the centripetal acceleration of the moon:

$$a_c = \frac{v^2}{r}$$

Express the orbital speed of the moon:

$$v = \frac{2\pi r}{T}$$

Substitute to obtain:

$$a_c = \frac{4\pi^2 r}{T^2}$$

Substitute numerical values and evaluate a_c:

$$a_c = \frac{4\pi^2 (3.84\times10^8\text{ m})}{\left(27.3\text{ d}\times\frac{24\text{ h}}{\text{d}}\times\frac{3600\text{ s}}{\text{h}}\right)^2}$$

$$= 2.72\times10^{-3}\text{ m/s}^2$$

$$= \boxed{2.78\times10^{-4}\,g}$$

Remarks: Note that $\dfrac{a_c}{g} = \dfrac{\textit{radius of earth}}{\textit{distance from earth to moon}}$ **(a_c is just the acceleration due to the earth's gravity evaluated at the moon's position). This is Newton's famous ″falling apple″ observation.**

75 •

Picture the Problem We can find the number of revolutions the ball makes in a given period of time from its speed and the radius of the circle along which it moves. Because the ball's centripetal acceleration is related to its speed, we can use this relationship to express its speed.

Express the number of revolutions per minute made by the ball in terms of the circumference c of the circle and the distance x the ball travels in time t:

$$n = \frac{x}{c} \qquad (1)$$

Relate the centripetal acceleration of the ball to its speed and the radius of its circular path:

$$a_c = g = \frac{v^2}{R}$$

Solve for the speed of the ball:

$$v = \sqrt{Rg}$$

Express the distance x traveled in time t at speed v:

$$x = vt$$

Substitute to obtain:

$$x = \sqrt{Rg}\,t$$

The distance traveled per revolution is the circumference c of the circle:

$$c = 2\pi R$$

Substitute in equation (1) to obtain:

$$n = \frac{\sqrt{Rg}\,t}{2\pi R} = \frac{1}{2\pi}\sqrt{\frac{g}{R}}\,t$$

Substitute numerical values and evaluate n:

$$n = \frac{1}{2\pi}\sqrt{\frac{9.81\,\text{m/s}^2}{0.8\,\text{m}}}(60\,\text{s}) = \boxed{33.4\,\text{min}^{-1}}$$

Remarks: The ball will oscillate at the end of this string as a simple pendulum with a period equal to 1/*n*.

Projectile Motion and Projectile Range

76 •

Picture the Problem Neglecting air resistance, the accelerations of the ball are constant and the horizontal and vertical motions of the ball are independent of each other. We can use the horizontal motion to determine the time-of-flight and then use this information to determine the distance the ball drops. Choose a coordinate system in which the origin is at the point of release of the ball, downward is the positive y direction, and the horizontal direction is the positive x direction.

Express the vertical displacement of the ball:

$$\Delta y = v_{0y}\Delta t + \tfrac{1}{2}a_y(\Delta t)^2$$

or, because $v_{0y} = 0$ and $a_y = g$,

$$\Delta y = \tfrac{1}{2}g(\Delta t)^2$$

Find the time of flight from $v_x = \Delta x/\Delta t$:

$$\Delta t = \frac{\Delta x}{v_x} = \frac{(18.4\,\text{m})(3600\,\text{s/h})}{(140\,\text{km/h})(1000\,\text{m/km})} = 0.473\,\text{s}$$

Substitute to find the vertical displacement in 0.473 s:

$$\Delta y = \tfrac{1}{2}(9.81\,\text{m/s}^2)(0.473\,\text{s})^2 = \boxed{1.10\,\text{m}}$$

77 •

Picture the Problem In the absence of air resistance, the maximum height achieved by a projectile depends on the vertical component of its initial velocity.

The vertical component of the projectile's initial velocity is:

$$v_{0y} = v_0 \sin\theta_0$$

Use the constant-acceleration equation:

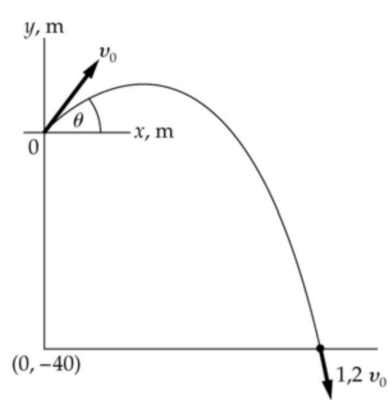
$$v_y^2 = v_{0y}^2 + 2a_y\Delta y$$

Set $v_y = 0$, $a = -g$, and $\Delta y = h$ to obtain:

$$h = \boxed{\frac{(v_0 \sin\theta_0)^2}{2g}}$$

***78** ••

Picture the Problem Choose the coordinate system shown to the right. Because, in the absence of air resistance, the horizontal and vertical speeds are independent of each other, we can use constant-acceleration equations to relate the impact speed of the projectile to its components.



The horizontal and vertical velocity components are:

$v_{0x} = v_x = v_0\cos\theta$
and
$v_{0y} = v_0\sin\theta$

Using a constant-acceleration equation, relate the vertical

$$v_y^2 = v_{0y}^2 + 2a_y\Delta y$$

or, because $a_y = -g$ and $\Delta y = -h$, component of the velocity to the vertical displacement of the projectile:

$$v_y^2 = (v_0 \sin\theta)^2 + 2gh$$

Express the relationship between the magnitude of a velocity vector and its components, substitute for the components, and simplify to obtain:

$$\begin{aligned} v^2 &= v_x^2 + v_y^2 = (v_0 \cos\theta)^2 + v_y^2 \\ &= v_0^2(\sin^2\theta + \cos^2\theta) + 2gh \\ &= v_0^2 + 2gh \end{aligned}$$

Substitute for v:

$$(1.2v_0)^2 = v_0^2 + 2gh$$

Set $v = 1.2\ v_0$, $h = 40$ m and solve for v_0:

$$v_0 = \boxed{42.2\,\text{m/s}}$$

Remarks: Note that *v* is independent of *θ*. This will be more obvious once conservation of energy has been studied.

79 ••

Picture the Problem Example 3-12 shows that the dart will hit the monkey unless the dart hits the ground before reaching the monkey's line of fall. What initial speed does the dart need in order to just reach the monkey's line of fall? First, we will calculate the fall time of the monkey, and then we will calculate the horizontal component of the dart's velocity.

Using a constant-acceleration equation, relate the monkey's fall distance to the fall time:

$$h = \tfrac{1}{2}gt^2$$

Solve for the time for the monkey to fall to the ground:

$$t = \sqrt{\frac{2h}{g}}$$

Substitute numerical values and evaluate t:

$$t = \sqrt{\frac{2(11.2\,\text{m})}{9.81\,\text{m/s}^2}} = 1.51\,\text{s}$$

Let θ be the angle the barrel of the dart gun makes with the horizontal. Then:

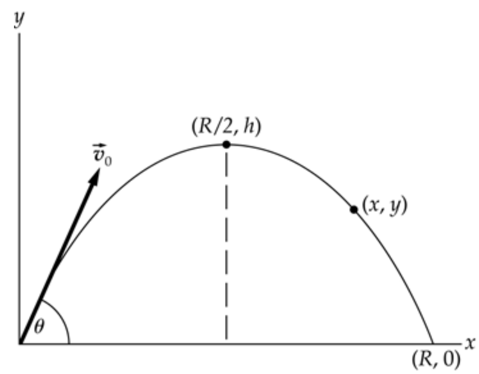
$$\theta = \tan^{-1}\left(\frac{10\,\text{m}}{50\,\text{m}}\right) = 11.3°$$

Use the fact that the horizontal velocity is constant to determine v_0:

$$v_0 = \frac{v_x}{\cos\theta} = \frac{(50\,\text{m}/1.51\,\text{s})}{\cos 11.3°} = \boxed{33.8\,\text{m/s}}$$

80 ••

Picture the Problem Choose the coordinate system shown in the figure to the right. In the absence of air resistance, the projectile experiences constant acceleration in both the x and y directions. We can use the constant-acceleration equations to express the x and y coordinates of the projectile along its trajectory as functions of time. The elimination of the parameter t will yield an expression for y as a function of x that we can evaluate at (R, 0) and (R/2, h). Solving these equations simultaneously will yield an expression for θ.



Express the position coordinates of the projectile along its flight path in terms of the parameter t:

$$x = (v_0 \cos\theta)t$$

and

$$y = (v_0 \sin\theta)t - \tfrac{1}{2}gt^2$$

Eliminate the parameter t to obtain:

$$y = (\tan\theta)x - \frac{g}{2v_0^2\cos^2\theta}x^2 \qquad (1)$$

Evaluate equation (1) at (R, 0) to obtain:

$$R = \frac{2v_0^2 \sin\theta\cos\theta}{g}$$

Evaluate equation (1) at (R/2, h) to obtain:

$$h = \frac{(v_0 \sin\theta)^2}{2g}$$

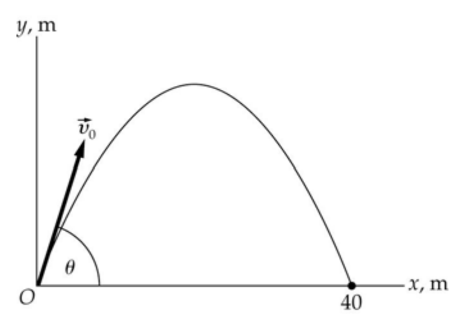
Equate R and h and solve the resulting equation for θ:

$$\theta = \tan^{-1}(4) = \boxed{76.0°}$$

Remarks: Note that this result is independent of v_0.

81 ••

Picture the Problem In the absence of air resistance, the motion of the ball is uniformly accelerated and its horizontal and vertical motions are independent of each other. Choose the coordinate system shown in the figure to the right and use constant-acceleration equations to relate the x and y components of the ball's initial velocity.



Use the components of v_0 to express θ in terms of v_{0x} and v_{0y}:

$$\theta = \tan^{-1}\frac{v_{0y}}{v_{0x}} \qquad (1)$$

Use the Pythagorean relationship between the velocity and its components to express v_0:

$$v_0 = \sqrt{v_{0x}^2 + v_{0y}^2} \qquad (2)$$

Using a constant-acceleration equation, express the vertical speed of the projectile as a function of its initial upward speed and time into the flight:

$$v_y = v_{0y} + a_y t$$

Because $v_y = 0$ halfway through the flight (at maximum elevation):

$$v_{0y} = (9.81\text{ m/s}^2)(1.22\text{ s}) = 12.0\text{ m/s}$$

Determine v_{0x}:

$$v_{0x} = \frac{\Delta x}{\Delta t} = \frac{40\text{ m}}{2.44\text{ s}} = 16.4\text{ m/s}$$

Substitute in equation (2) and evaluate v_0:

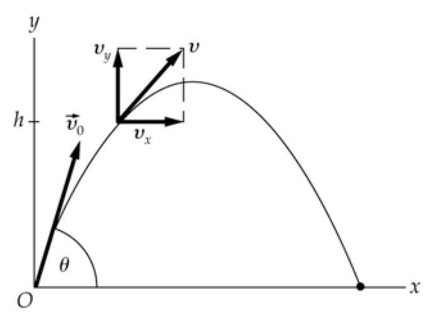
$$v_0 = \sqrt{(16.4\text{ m/s})^2 + (12.0\text{ m/s})^2} = \boxed{20.3\text{ m/s}}$$

Substitute in equation (1) and evaluate θ:

$$\theta = \tan^{-1}\left(\frac{12.0\text{ m/s}}{16.4\text{ m/s}}\right) = \boxed{36.2°}$$

***82** ••

Picture the Problem In the absence of friction, the acceleration of the ball is constant and we can use the constant-acceleration equations to describe its motion. The figure shows the launch conditions and an appropriate coordinate system. The speeds v, v_x, and v_y are related through the Pythagorean Theorem.



The squares of the vertical and horizontal components of the object's velocity are:

$$v_y^2 = v_0^2 \sin^2\theta - 2gh$$

and

$$v_x^2 = v_0^2 \cos^2\theta$$

The relationship between these variables is:

$$v^2 = v_x^2 + v_y^2$$

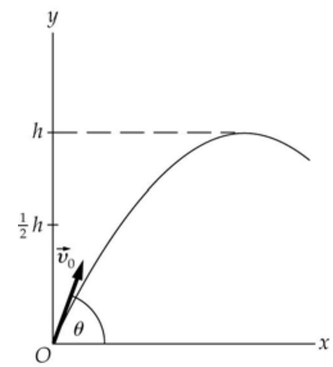
Substitute and simplify to obtain:

$$v^2 = \boxed{v_0^2 - 2gh}$$

Note that v is independent of θ ... as was to be shown.

83 ••

Picture the Problem In the absence of air resistance, the projectile experiences constant acceleration during its flight and we can use constant-acceleration equations to relate the speeds at half the maximum height and at the maximum height to the launch angle θ of the projectile.



The angle the initial velocity makes with the horizontal is related to the initial velocity components.

$$\tan\theta = \frac{v_{0y}}{v_{0x}}$$

Write the equation $v_y^2 = v_{0y}^2 + 2a\Delta y$, for $\Delta y = h$ and $v_y = 0$:

$$\Delta y = h \Rightarrow 0 = v_{0y}^2 - 2gh \qquad (1)$$

Write the equation $v_y^2 = v_{0y}^2 + 2a\Delta y$, for $\Delta y = h/2$:

$$\Delta y = \frac{h}{2} \Rightarrow v_y^2 = v_{0y}^2 - 2g\frac{h}{2} \qquad (2)$$

We are given $v_y = (3/4)v_0$. Square both sides and express this using the components of the velocity. The x component of the velocity remains constant.

$$v_{0x}^2 + v_y^2 = \left(\frac{3}{4}\right)^2\left(v_{0x}^2 + v_{0y}^2\right) \qquad (3)$$

where we have used $v_x = v_{0x}$.

(Equations 1, 2, and 3 constitute three equations and four unknowns v_{0x}, v_{0y}, v_y, and h. To solve for any of these unknowns, we first need a fourth equation. However, to solve for the ratio (v_{0y}/v_{0x}) of two of the unknowns, the three equations are sufficient. That is because dividing both sides of each equation by v_{0x}^2 gives three equations and three unknowns v_y/v_{0x}, v_{0y}/v_{0x}, and h/v_{0x}^2.

Solve equation 2 for gh and substitute in equation 1:

$$v_{0y}^2 = 2\left(v_{0y}^2 - v_h^2\right) \Rightarrow v_y^2 = \frac{v_{0y}^2}{2}$$

Substitute for v_y^2 in equation 3:

$$v_{0x}^2 + \frac{1}{2}v_{0y}^2 = \left(\frac{3}{4}\right)^2\left(v_{0x}^2 + v_{0y}^2\right)$$

Divide both sides by v_{0x}^2 and solve for v_{0y}/v_{0x} to obtain:

$$1+\frac{1}{2}\frac{v_{0y}^2}{v_{0x}^2}=\frac{9}{16}\left(1+\frac{v_{0y}^2}{v_{0x}^2}\right)$$

and

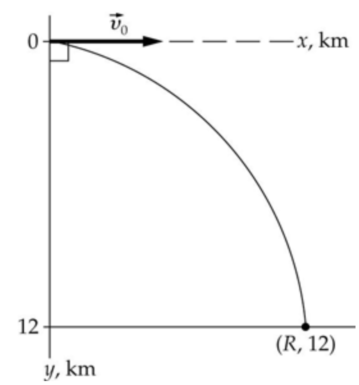
$$\frac{v_{0y}}{v_{0x}}=\sqrt{7}$$

Using $\tan\theta = v_{0y}/v_{0x}$, solve for θ:

$$\theta=\tan^{-1}\left(\frac{v_{0y}}{v_{0x}}\right)=\tan^{-1}\left(\sqrt{7}\right)=\boxed{69.3°}$$

84 •

Picture the Problem The horizontal speed of the crate, in the absence of air resistance, is constant and equal to the speed of the cargo plane. Choose a coordinate system in which the direction the plane is moving is the positive *x* direction and downward is the positive *y* direction and apply the constant-acceleration equations to describe the crate's displacements at any time during its flight.



(*a*) Using a constant-acceleration equation, relate the vertical displacement of the crate Δy to the time of fall Δt:

$$\Delta y=v_{0y}\Delta t+\tfrac{1}{2}g(\Delta t)^2$$

or, because $v_{0y}=0$,

$$\Delta y=\tfrac{1}{2}g(\Delta t)^2$$

Solve for Δt:

$$\Delta t=\sqrt{\frac{2\Delta y}{g}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t=\sqrt{\frac{2\left(12\times10^3\text{ m}\right)}{9.81\text{m/s}^2}}=\boxed{49.5\text{s}}$$

(*b*) The horizontal distance traveled in 49.5 s is:

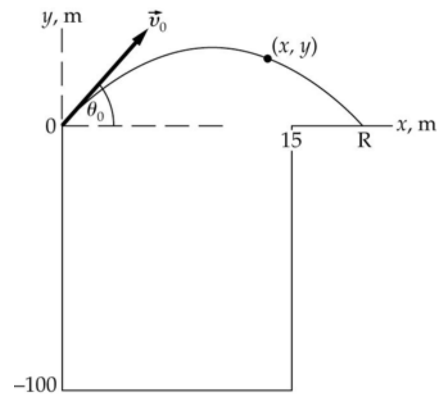
$$R=\Delta x=v_{0x}\Delta t$$
$$=(900\text{km/h})\left(\frac{1\text{h}}{3600\text{s}}\right)(49.5\text{s})$$
$$=\boxed{12.4\text{km}}$$

(*c*) Because the velocity of the plane is constant, it will be directly over the crate when it hits the ground; i.e., the distance to the aircraft will be the elevation of the aircraft.

$$\Delta y=\boxed{12.0\text{km}}$$

***85 ••**

Picture the Problem In the absence of air resistance, the accelerations of both Wiley Coyote and the Roadrunner are constant and we can use constant-acceleration equations to express their coordinates at any time during their leaps across the gorge. By eliminating the parameter t between these equations, we can obtain an expression that relates their y coordinates to their x coordinates and that we can solve for their launch angles.



(*a*) Using constant-acceleration equations, express the x coordinate of the Roadrunner while it is in flight across the gorge:

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$

or, because $x_0 = 0$, $a_x = 0$ and $v_{0x} = v_0 \cos\theta_0$,

$$x = (v_0 \cos\theta_0)t$$

Using constant-acceleration equations, express the y coordinate of the Roadrunner while it is in flight across the gorge:

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$

or, because $y_0 = 0$, $a_y = -g$ and $v_{0y} = v_0 \sin\theta_0$,

$$y = (v_0 \sin\theta_0)t - \tfrac{1}{2}gt^2$$

Eliminate the parameter t to obtain:

$$y = (\tan\theta_0)x - \frac{g}{2v_0^2\cos^2\theta_0}x^2 \qquad (1)$$

Letting R represent the Roadrunner's range and using the trigonometric identity $\sin 2\theta = 2\sin\theta\cos\theta$, solve for and evaluate its launch speed:

$$v_0 = \sqrt{\frac{Rg}{\sin 2\theta_0}} = \sqrt{\frac{(16.5\,\text{m})(9.81\,\text{m/s}^2)}{\sin 30°}}$$

$$= \boxed{18.0\,\text{m/s}}$$

(*b*) Letting R represent Wiley's range, solve equation (1) for his launch angle:

$$\theta_0 = \frac{1}{2}\sin^{-1}\left(\frac{Rg}{v_0^2}\right)$$

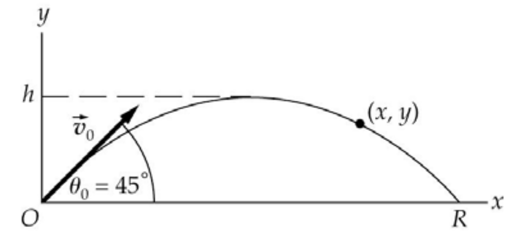
Substitute numerical values and evaluate θ_0:

$$\theta_0 = \frac{1}{2}\sin^{-1}\left[\frac{(14.5\,\text{m})(9.81\,\text{m/s}^2)}{(18.0\,\text{m/s})^2}\right]$$

$$= \boxed{13.0°}$$

86 •

Picture the Problem Because, in the absence of air resistance, the vertical and horizontal accelerations of the cannonball are constant, we can use constant-acceleration equations to express the ball's position and velocity as functions of time and acceleration. The maximum height of the ball and its time-of-flight are related to the components of its launch velocity.



(*a*) Using a constant-acceleration equation, relate *h* to the initial and final speeds of the cannonball:

$$v^2 = v_{0y}^2 + 2a_y\Delta y$$

or, because $v = 0$ and $a_y = -g$,

$$0 = v_{0y}^2 - 2g\Delta y$$

Find the vertical component of the firing speed:

$$v_{0y} = v_0 \sin\theta = (300\text{ m/s})\sin 45° = 212\text{ m/s}$$

Solve for and evaluate *h*:

$$h = \frac{v_{0y}^2}{2g} = \frac{(212\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)} = \boxed{2.29\,\text{km}}$$

(*b*) The total flight time is:

$$\Delta t = t_{\text{up}} + t_{\text{dn}} = 2t_{\text{up}} = 2\frac{v_{0y}}{g} = \frac{2(212\,\text{m/s})}{9.81\,\text{m/s}^2} = \boxed{43.2\,\text{s}}$$

(*c*) Express the *x* coordinate of the ball as a function of time:

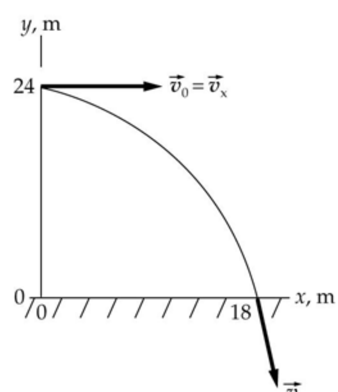
$$x = v_{0x}\Delta t = (v_0\cos\theta)\Delta t$$

Evaluate *x* (= *R*) when $\Delta t = 43.2$ s:

$$x = [(300\,\text{m/s})\cos 45°](43.2\,\text{s}) = \boxed{9.16\,\text{km}}$$

87 ••

Picture the Problem Choose a coordinate system in which the origin is at the base of the tower and the *x*- and *y*-axes are as shown in the figure to the right. In the absence of air resistance, the horizontal speed of the stone will remain constant during its fall and a constant-acceleration equation can be used to determine the time of fall. The final velocity of the stone will be the vector sum of its *x* and *y* components.



(*a*) Using a constant-acceleration equation, express the vertical displacement of the stone (the height of the tower) as a function of the fall time:

$$\Delta y = v_{0y}\Delta t + \tfrac{1}{2}a_y(\Delta t)^2$$

or, because $v_{0y} = 0$ and $a = -g$,

$$\Delta y = -\tfrac{1}{2}g(\Delta t)^2$$

Solve for and evaluate the time of fall:

$$\Delta t = \sqrt{-\frac{2\Delta y}{g}} = \sqrt{-\frac{2(-24\,\text{m})}{9.81\,\text{m/s}^2}} = 2.21\,\text{s}$$

Use the definition of average velocity to find the velocity with which the stone was thrown from the tower:

$$v_x = v_{0x} \equiv \frac{\Delta x}{\Delta t} = \frac{18\,\text{m}}{2.21\,\text{s}} = \boxed{8.14\,\text{m/s}}$$

(*b*) Find the *y* component of the stone's velocity after 2.21 s:

$$v_y = v_{0y} - gt$$
$$= 0 - (9.81\,\text{m/s2})(2.21\,\text{s})$$
$$= -21.7\,\text{m/s}$$

Express *v* in terms of its components:

$$v = \sqrt{v_x^2 + v_y^2}$$

Substitute numerical values and evaluate *v*:

$$v = \sqrt{(8.14\,\text{m/s})^2 + (-21.7\,\text{m/s})^2}$$
$$= \boxed{23.2\,\text{m/s}}$$

88 ••

Picture the Problem In the absence of air resistance, the acceleration of the projectile is constant and its horizontal and vertical motions are independent of each other. We can use constant-acceleration equations to express the horizontal and vertical displacements of the projectile in terms of its time-of-flight.

Using a constant-acceleration equation, express the horizontal displacement of the projectile as a function of time:

$$\Delta x = v_{0x}\Delta t + \tfrac{1}{2}a_x(\Delta t)^2$$

or, because $v_{0x} = v_0\cos\theta$ and $a_x = 0$,

$$\Delta x = (v_0\cos\theta)\Delta t$$

Using a constant-acceleration equation, express the vertical displacement of the projectile as a function of time:

$$\Delta y = v_{0y}\Delta t + \tfrac{1}{2}a_y(\Delta t)^2$$

or, because $v_{0y} = v_0\sin\theta$ and $a_y = -g$,

$$\Delta y = (v_0\cos\theta)\Delta t - \tfrac{1}{2}g(\Delta t)^2$$

Substitute numerical values to obtain the quadratic equation:

$$-200\,\text{m} = (60\,\text{m/s})(\sin 60°)\Delta t - \tfrac{1}{2}(9.81\,\text{m/s}^2)(\Delta t)^2$$

Solve for Δt:

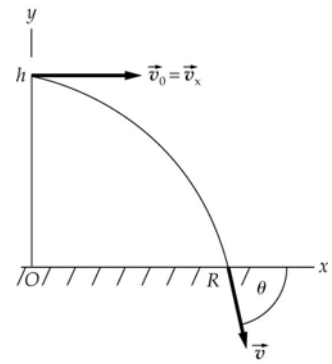
$$\Delta t = 13.6\text{ s}$$

Substitute for Δt and evaluate the horizontal distance traveled by the projectile:

$$\Delta x = (60\text{ m/s})(\cos 60°)(13.6\text{ s}) = \boxed{408\text{ m}}$$

89 ••

Picture the Problem In the absence of air resistance, the acceleration of the cannonball is constant and its horizontal and vertical motions are independent of each other. Choose the origin of the coordinate system to be at the base of the cliff and the axes directed as shown and use constant- acceleration equations to describe both the horizontal and vertical displacements of the cannonball.



Express the direction of the velocity vector when the projectile strikes the ground:

$$\theta = \tan^{-1}\left(\frac{v_y}{v_x}\right)$$

Express the vertical displacement using a constant-acceleration equation:

$$\Delta y = v_{0y}\Delta t + \tfrac{1}{2}a_y(\Delta t)^2$$

or, because $v_{0y} = 0$ and $a_y = -g$,

$$\Delta y = -\tfrac{1}{2}g(\Delta t)^2$$

Set $\Delta x = -\Delta y$ ($R = -h$) to obtain:

$$\Delta x = v_x\Delta t = \tfrac{1}{2}g(\Delta t)^2$$

Solve for v_x:

$$v_x = \frac{\Delta x}{\Delta t} = \tfrac{1}{2}g\Delta t$$

Find the y component of the projectile as it hits the ground:

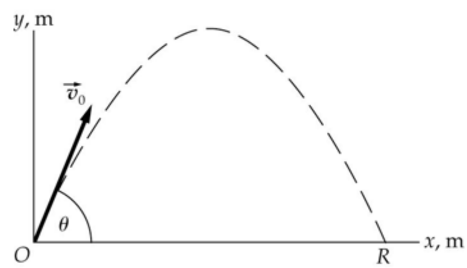
$$v_y = v_{0y} + a\Delta t = -g\Delta t = -2v_x$$

Substitute and evaluate θ:

$$\theta = \tan^{-1}\left(\frac{v_y}{v_x}\right) = \tan^{-1}(-2) = \boxed{-63.4°}$$

90 •

Picture the Problem In the absence of air resistance, the vertical and horizontal motions of the projectile experience constant accelerations and are independent of each other. Use a coordinate system in which up is the positive y direction and horizontal is the positive x direction and use constant-acceleration equations to describe the horizontal and vertical displacements of the projectile as functions of the time into the flight.



(*a*) Use a constant-acceleration equation to express the horizontal displacement of the projectile as a function of time:

$$\Delta x = v_{0x}\Delta t = (v_0 \cos\theta)\Delta t$$

Evaluate this expression when $\Delta t = 6$ s:

$$\Delta x = (300\,\text{m/s})(\cos 60°)(6\,\text{s}) = \boxed{900\,\text{m}}$$

(*b*) Use a constant-acceleration equation to express the vertical displacement of the projectile as a function of time:

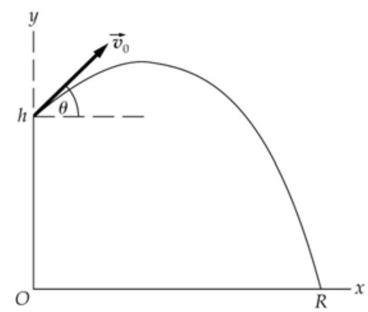
$$\Delta y = (v_0 \sin\theta)\Delta t - \tfrac{1}{2}g(\Delta t)^2$$

Evaluate this expression when $\Delta t = 6$ s:

$$\Delta y = (300\,\text{m/s})(\sin 60°)(6\,\text{s}) - \tfrac{1}{2}(9.81\,\text{m/s}^2)(6\,\text{s})^2 = \boxed{1.38\,\text{km}}$$

91 ••

Picture the Problem In the absence of air resistance, the acceleration of the projectile is constant and the horizontal and vertical motions are independent of each other. Choose the coordinate system shown in the figure with the origin at the base of the cliff and the axes oriented as shown and use constant-acceleration equations to find the range of the cannonball.



Using a constant-acceleration equation, express the horizontal displacement of the cannonball as a function of time:

$$\Delta x = v_{0x}\Delta t + \tfrac{1}{2}a_x(\Delta t)^2$$

or, because $v_{0x} = v_0\cos\theta$ and $a_x = 0$,

$$\Delta x = (v_0 \cos\theta)\Delta t$$

Using a constant-acceleration equation, express the vertical displacement of the cannonball as a function of time:

$$\Delta y = v_{0y}\Delta t + \tfrac{1}{2}a_y(\Delta t)^2$$

or, because $y = -40$ m, $a = -g$, and $v_{0y} = v_0\sin\theta$,

$$-40\,\text{m} = (42.2\,\text{m/s})(\sin 30°)\Delta t - \tfrac{1}{2}(9.81\,\text{m/s}^2)(\Delta t)^2$$

Solve the quadratic equation for Δt:

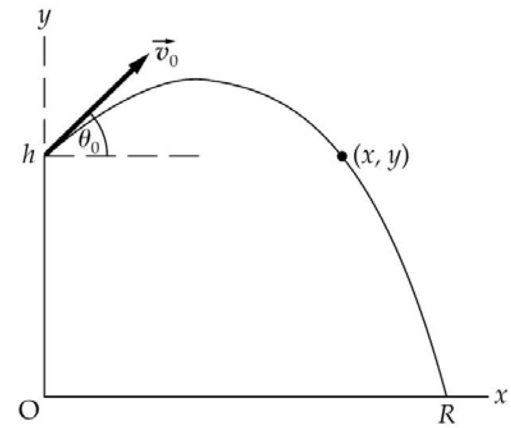
$$\Delta t = 5.73 \text{ s}$$

Calculate the range:

$$R = \Delta x = (42.2\,\text{m/s})(\cos 30°)(5.73\,\text{s}) = \boxed{209\,\text{m}}$$

***92** ••

Picture the Problem Choose a coordinate system in which the origin is at ground level. Let the positive *x* direction be to the right and the positive *y* direction be upward. We can apply constant-acceleration equations to obtain parametric equations in time that relate the range to the initial horizontal speed and the height *h* to the initial upward speed. Eliminating the parameter will leave us with a quadratic equation in *R,* the solution to which will give us the range of the arrow. In (*b*), we'll find the launch speed and angle as viewed by an observer who is at rest on the ground and then use these results to find the arrow's range when the horse is moving at 12 m/s.



(*a*) Use constant-acceleration equations to express the horizontal and vertical coordinates of the arrow's motion:

$$R = \Delta x = x - x_0 = v_{0x}t$$

and

$$y = h + v_{0y}t + \tfrac{1}{2}(-g)t^2$$

where

$$v_{0x} = v_0\cos\theta \text{ and } v_{0y} = v_0\sin\theta$$

Solve the *x*-component equation for time:

$$t = \frac{R}{v_{0x}} = \frac{R}{v_0\cos\theta}$$

Eliminate time from the *y*-component equation:

$$y = h + v_{0y}\frac{R}{v_{0x}} - \frac{1}{2}g\left(\frac{R}{v_{0x}}\right)^2$$

and, at (*R*, 0),

$$0 = h + (\tan\theta)R - \frac{g}{2v_0^2\cos^2\theta}R^2$$

Solve for the range to obtain:

$$R = \frac{v_0^2}{2g}\sin 2\theta\left(1 + \sqrt{1 + \frac{2gh}{v_0^2\sin^2\theta}}\right)$$

Substitute numerical values and evaluate *R*:

$$R = \frac{(45\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)}\sin 20°\left(1 + \sqrt{1 + \frac{2(9.81\,\text{m/s}^2)(2.25\,\text{m})}{(45\,\text{m/s})^2(\sin^2 10°)}}\right) = \boxed{81.6\,\text{m}}$$

(*b*) Express the speed of the arrow in the horizontal direction:

$$v_x = v_{\text{arrow}} + v_{\text{archer}} = (45\,\text{m/s})\cos 10° + 12\,\text{m/s} = 56.3\,\text{m/s}$$

Express the vertical speed of the arrow:

$$v_y = (45\,\text{m/s})\sin 10° = 7.81\,\text{m/s}$$

Express the angle of elevation from the perspective of someone on the ground:

$$\theta = \tan^{-1}\left(\frac{v_y}{v_x}\right) = \tan^{-1}\left(\frac{7.81\,\text{m/s}}{56.3\,\text{m/s}}\right) = 7.90°$$

Express the arrow's speed relative to the ground:

$$v_0 = \sqrt{v_x^2 + v_y^2} = \sqrt{(56.3\,\text{m/s})^2 + (7.81\,\text{m/s})^2} = 56.8\,\text{m/s}$$

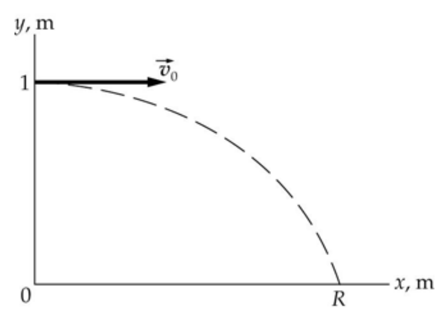
Substitute numerical values and evaluate *R*:

$$R = \frac{(56.8\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)}\sin 15.8°\left(1 + \sqrt{1 + \frac{2(9.81\,\text{m/s}^2)(2.25\,\text{m})}{(56.8\,\text{m/s})^2(\sin^2 7.9°)}}\right) = \boxed{104\,\text{m}}$$

Remarks: An alternative solution for part (*b*) is to solve for the range in the reference frame of the archer and then add to it the distance the frame travels, relative to the earth, during the time of flight.

93 •

Picture the Problem In the absence of air resistance, the horizontal and vertical motions are independent of each other. Choose a coordinate system oriented as shown in the figure to the right and apply constant-acceleration equations to find the time-of-flight and the range of the spud-plug.



(*a*) Using a constant-acceleration equation, express the vertical displacement of the plug:

$$\Delta y = v_{0y}\Delta t + \tfrac{1}{2}a_y(\Delta t)^2$$

or, because $v_{0y} = 0$ and $a_y = -g$,

$$\Delta y = -\tfrac{1}{2}g(\Delta t)^2$$

Solve for and evaluate the flight time Δt:

$$\Delta t = \sqrt{-\frac{2\Delta y}{g}} = \sqrt{-\frac{2(-1.00\,\text{m})}{9.81\,\text{m/s}^2}} = \boxed{0.452\,\text{s}}$$

(*b*) Using a constant-acceleration equation, express the horizontal displacement of the plug:

$$\Delta x = v_{0x}\Delta t + \tfrac{1}{2}a_x(\Delta t)^2$$

or, because $a_x = 0$ and $v_{0x} = v_0$,

$$\Delta x = v_0\Delta t$$

Substitute numerical values and evaluate R:

$$\Delta x = R = (50\,\text{m/s})(0.452\,\text{s}) = \boxed{22.6\,\text{m}}$$

94 ••

Picture the Problem An extreme value (i.e., a maximum or a minimum) of a function is determined by setting the appropriate derivative equal to zero. Whether the extremum is a maximum or a minimum can be determined by evaluating the second derivative at the point determined by the first derivative.

Evaluate $dR/d\theta_0$:

$$\frac{dR}{d\theta_0} = \frac{v_0^2}{g}\frac{d}{d\theta_0}[\sin(2\theta_0)] = \frac{2v_0^2}{g}\cos(2\theta_0)$$

Set $dR/d\theta_0 = 0$ for extrema and solve for θ_0:

$$\frac{2v_0^2}{g}\cos(2\theta_0) = 0$$

and

$$\theta_0 = \tfrac{1}{2}\cos^{-1}0 = 45°$$

Determine whether 45° is a maximum or a minimum:

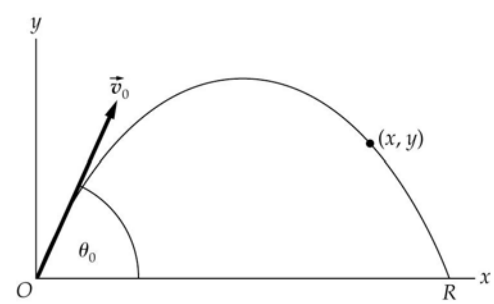
$$\left.\frac{d^2R}{d\theta_0^{\,2}}\right|_{\theta_0=45°} = \left[-4\left(v_0^2/g\right)\sin 2\theta_0\right]_{\theta_0=45°}$$

$$< 0$$

$\therefore$ R is a maximum at $\theta_0 = 45°$

95 •

Picture the Problem We can use constant-acceleration equations to express the x and y coordinates of a bullet in flight on the moon as a function of t. Eliminating this parameter will yield an expression for y as a function of x that we can use to find the range of the bullet. The necessity that the centripetal acceleration of an object in orbit at the surface of a body equal the acceleration due to gravity at the surface will allow us to determine the required muzzle velocity for orbital motion.



(*a*) Using a constant-acceleration equation, express the x coordinate of a bullet in flight on the moon:

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_xt^2$$

or, because $x_0 = 0$, $a_x = 0$ and $v_{0x} = v_0\cos\theta_0$,

$$x = (v_0\cos\theta_0)t$$

Using a constant-acceleration equation, express the y coordinate of a bullet in flight on the moon:

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$

or, because $y_0 = 0$, $a_y = -g_{\text{moon}}$ and $v_{0y} = v_0\sin\theta_0$,

$$y = (v_0 \sin\theta_0)t - \tfrac{1}{2}g_{\text{moon}}t^2$$

Eliminate the parameter t to obtain:

$$y = (\tan\theta_0)x - \frac{g_{\text{moon}}}{2v_0^2\cos^2\theta_0}x^2$$

When $y = 0$ and $x = R$:

$$0 = (\tan\theta_0)R - \frac{g_{\text{moon}}}{2v_0^2\cos^2\theta_0}R^2$$

and

$$R = \frac{v_0^2}{g_{\text{moon}}}\sin 2\theta_0$$

Substitute numerical values and evaluate R:

$$R = \frac{(900\,\text{m/s})^2}{1.67\,\text{m/s}^2}\sin 90° = 4.85\times10^5\,\text{m}$$
$$= \boxed{485\,\text{km}}$$

This result is probably not very accurate because it is about 28% of the moon's radius (1740 km). This being the case, we can no longer assume that the ground is "flat" because of the curvature of the moon.

(*b*) Express the condition that the centripetal acceleration must satisfy for an object in orbit at the surface of the moon:

$$a_c = g_{\text{moon}} = \frac{v^2}{r}$$

Solve for and evaluate v:

$$v = \sqrt{g_{\text{moon}}r} = \sqrt{(1.67\,\text{m/s}^2)(1.74\times10^6\,\text{m})}$$
$$= \boxed{1.70\,\text{km/s}}$$

96 •••

Picture the Problem We can show that $\Delta R/R = -\Delta g/g$ by differentiating R with respect to g and then using a differential approximation.

Differentiate the range equation with respect to g:

$$\frac{dR}{dg} = \frac{d}{dg}\left(\frac{v_0^2}{g}\sin 2\theta_0\right) = -\frac{v_0^2}{g^2}\sin 2\theta_0$$
$$= -\frac{R}{g}$$

Approximate dR/dg by $\Delta R/\Delta g$:

$$\frac{\Delta R}{\Delta g}=-\frac{R}{g}$$

Separate the variables to obtain:

$$\frac{\Delta R}{R}=-\frac{\Delta g}{g}$$

i.e., for small changes in gravity ($g\approx g\pm\Delta g$), the fractional change in R is linearly opposite to the fractional change in g.

Remarks: This tells us that as gravity increases, the range will decrease, and vice versa. This is as it must be because *R* is inversely proportional to *g*.

97 •••

Picture the Problem We can show that $\Delta R/R = 2\Delta v_0/ v_0$ by differentiating R with respect to v_0 and then using a differential approximation.

Differentiate the range equation with respect to v_0:

$$\frac{dR}{dv_0}=\frac{d}{dv_0}\left(\frac{v_0^2}{g}\sin 2\theta_0\right)=\frac{2v_0}{g}\sin 2\theta_0$$

$$=2\frac{R}{v_0}$$

Approximate dR/dv_0 by $\Delta R/\Delta v_0$:

$$\frac{\Delta R}{\Delta v_0}=2\frac{R}{v_0}$$

Separate the variables to obtain:

$$\frac{\Delta R}{R}=2\frac{\Delta v_0}{v_0}$$

i.e., for small changes in the launch velocity ($v_0\approx v_0\pm\Delta v_0$), the fractional change in R is twice the fractional change in v_0.

Remarks: This tells us that as launch velocity increases, the range will increase twice as fast, and vice versa.

98 •••

Picture the Problem Choose a coordinate system in which the origin is at the base of the surface from which the projectile is launched. Let the positive x direction be to the right and the positive y direction be upward. We can apply constant-acceleration equations to obtain parametric equations in time that relate the range to the initial horizontal speed and the height h to the initial upward speed. Eliminating the parameter will leave us with a quadratic equation in R, the solution to which is the result we are required to establish.

Write the constant-acceleration equations for the horizontal and vertical parts of the projectile's

$$x=v_{0x}t$$

and

motion:

$$y = h + v_{0y}t + \tfrac{1}{2}(-g)t^2$$

where

$v_{0x} = v_0 \cos\theta$ and $v_{0y} = v_0 \sin\theta$

Solve the x-component equation for time:

$$t = \frac{x}{v_{0x}} = \frac{x}{v_0 \cos\theta}$$

Using the x-component equation, eliminate time from the y-component equation to obtain:

$$y = h + (\tan\theta)x - \frac{g}{2v_0^2 \cos^2\theta}x^2$$

When the projectile strikes the ground its coordinates are (R, 0) and our equation becomes:

$$0 = h + (\tan\theta)R - \frac{g}{2v_0^2 \cos^2\theta}R^2$$

Using the plus sign in the quadratic formula to ensure a physically meaningful root (one that is positive), solve for the range to obtain:

$$R = \boxed{\left(1 + \sqrt{1 + \frac{2gh}{v_0^2 \sin^2\theta_0}}\right)\frac{v_0^2}{2g}\sin 2\theta_0}$$

***99 ••**

Picture the Problem We can use trigonometry to relate the maximum height of the projectile to its range and the sighting angle at maximum elevation and the range equation to express the range as a function of the launch speed and angle. We can use a constant-acceleration equation to express the maximum height reached by the projectile in terms of its launch angle and speed. Combining these relationships will allow us to conclude that $\tan\phi = \tfrac{1}{2}\tan\theta$.

Referring to the figure, relate the maximum height of the projectile to its range and the sighting angle ϕ:

$$\tan\phi = \frac{h}{R/2}$$

Express the range of the rocket and use the trigonometric identity $\sin 2\theta = 2\sin\theta\cos\theta$ to rewrite the expression as:

$$R = \frac{v^2}{g}\sin(2\theta) = 2\frac{v^2}{g}\sin\theta\cos\theta$$

Using a constant-acceleration equation, relate the maximum height of a projectile to the vertical component of its launch speed:

$$v_y^2 = v_{0y}^2 - 2gh$$

or, because $v_y = 0$ and $v_{0y} = v_0\sin\theta$,

$$v_0^2 \sin^2\theta = 2gh$$

Solve for the maximum height h:

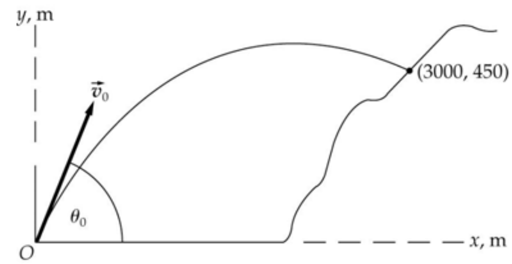
$$h = \frac{v^2}{2g}\sin^2\theta$$

Substitute for R and h and simplify to obtain:

$$\tan\phi = \frac{2\frac{v^2}{2g}\sin^2\theta}{2\frac{v^2}{g}\sin\theta\cos\theta} = \boxed{\tfrac{1}{2}\tan\theta}$$

100 •

Picture the Problem In the absence of air resistance, the horizontal and vertical displacements of the projectile are independent of each other and describable by constant-acceleration equations. Choose the origin at the firing location and with the coordinate axes as shown in the figure and use constant-acceleration equations to relate the vertical displacement to vertical component of the initial velocity and the horizontal velocity to the horizontal displacement and the time of flight.



(*a*) Using a constant-acceleration equation, express the vertical displacement of the projectile as a function of its time of flight:

$$\Delta y = v_{0y}\Delta t + \tfrac{1}{2}a_y(\Delta t)^2$$

or, because $a_y = -g$,

$$\Delta y = v_{0y}\Delta t - \tfrac{1}{2}g(\Delta t)^2$$

Solve for v_{0y}:

$$v_{0y} = \frac{\Delta y + \frac{1}{2}g(\Delta t)^2}{\Delta t}$$

Substitute numerical values and evaluate v_{0y}:

$$v_{0y} = \frac{450\,\text{m} + \frac{1}{2}(9.81\,\text{m/s}^2)(20\,\text{s})^2}{20\,\text{s}}$$

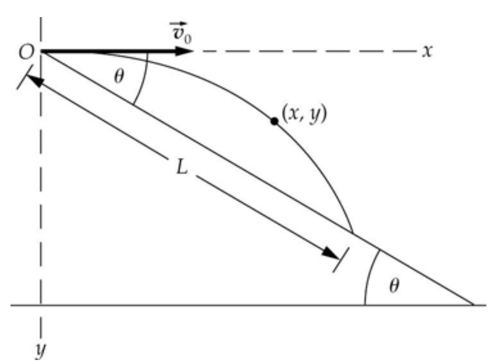
$$= \boxed{121\,\text{m/s}}$$

(*b*) The horizontal velocity remains constant, so:

$$v_{0x} = v_x = \frac{\Delta x}{\Delta t} = \frac{3000\,\text{m}}{20\,\text{s}} = \boxed{150\,\text{m/s}}$$

***101** ••

Picture the Problem In the absence of air resistance, the acceleration of the stone is constant and the horizontal and vertical motions are independent of each other. Choose a coordinate system with the origin at the throwing location and the axes oriented as shown in the figure and use constant- acceleration equations to express the x and y coordinates of the stone while it is in flight.



Using a constant-acceleration equation, express the x coordinate of the stone in flight:

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$

or, because $x_0 = 0$, $v_{0x} = v_0$ and $a_x = 0$,

$$x = v_0 t$$

Using a constant-acceleration equation, express the y coordinate of the stone in flight:

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$

or, because $y_0 = 0$, $v_{0y} = 0$ and $a_y = g$,

$$y = \tfrac{1}{2}gt^2$$

Referring to the diagram, express the relationship between θ, y and x at impact:

$$\tan\theta = \frac{y}{x}$$

Substitute for x and y and solve for the time to impact:

$$\tan\theta = \frac{gt^2}{2v_0 t} = \frac{g}{2v_0}t$$

Solve for t to obtain:

$$t = \frac{2v_0}{g}\tan\theta$$

Referring to the diagram, express the relationship between θ, L, y and x at impact:

$$x = L\cos\theta = \frac{y}{\tan\theta}$$

Substitute for y to obtain:

$$\frac{gt^2}{2g} = L\cos\theta$$

Substitute for t and solve for L to obtain:

$$L = \boxed{\frac{2v_0^2\tan\theta}{g\cos\theta}}$$

102 •••

Picture the Problem The equation of a particle's trajectory is derived in the text so we'll use it as our starting point in this derivation. We can relate the coordinates of the point of impact (x, y) to the angle ϕ and use this relationship to eliminate y from the equation for the cannonball's trajectory. We can then solve the resulting equation for x and relate the horizontal component of the point of impact to the cannonball's range.

The equation of the cannonball's trajectory is given in the text:

$$y(x) = (\tan\theta_0)x - \left(\frac{g}{2v_0^2\cos^2\theta_0}\right)x^2$$

Relate the x and y components of a point on the ground to the angle ϕ:

$$y(x) = (\tan\phi)x$$

Express the condition that the cannonball hits the ground:

$$(\tan\phi)x = (\tan\theta_0)x - \left(\frac{g}{2v_0^2\cos^2\theta_0}\right)x^2$$

Solve for x to obtain:

$$x = \frac{2v_0^2 \cos^2\theta_0 (\tan\theta_0 - \tan\phi)}{g}$$

Relate the range of the cannonball's flight R to the horizontal distance x:

$$x = R\cos\phi$$

Substitute to obtain:

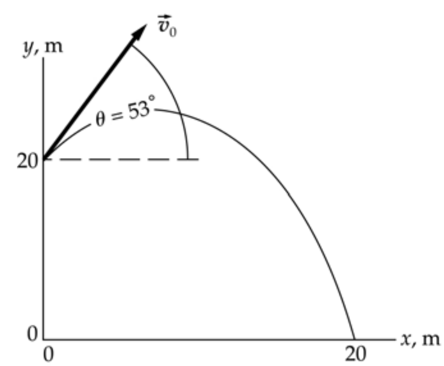
$$R\cos\phi = \frac{2v_0^2 \cos^2\theta_0 (\tan\theta_0 - \tan\phi)}{g}$$

Solve for R:

$$R = \boxed{\frac{2v_0^2 \cos^2\theta_0 (\tan\theta_0 - \tan\phi)}{g\cos\phi}}$$

103 ••

Picture the Problem In the absence of air resistance, the acceleration of the rock is constant and the horizontal and vertical motions are independent of each other. Choose the coordinate system shown in the figure with the origin at the base of the building and the axes oriented as shown and apply constant-acceleration equations to relate the horizontal and vertical displacements of the rock to its time of flight.



Find the horizontal and vertical components of v_0:

$$v_{0x} = v_0 \cos 53° = 0.602 v_0$$
$$v_{0y} = v_0 \sin 53° = 0.799 v_0$$

Using a constant-acceleration equation, express the horizontal displacement of the projectile:

$$\Delta x = 20\,\text{m} = v_{0x}\Delta t = (0.602 v_0)\Delta t$$

Using a constant-acceleration equation, express the vertical displacement of the projectile:

$$\Delta y = -20\,\text{m} = v_{0y}\Delta t - \tfrac{1}{2} g(\Delta t)^2$$
$$= (0.799 v_0)\Delta t - \tfrac{1}{2} g(\Delta t)^2$$

Solve the x-displacement equation for Δt:

$$\Delta t = \frac{20\,\text{m}}{0.602 v_0}$$

Substitute Δt into the expression for Δy:

$$-20\text{ m} = (0.799 v_0)\Delta t - (4.91\text{ m/s}^2)(\Delta t)^2$$

Solve for v_0 to obtain:

$$v_0 = \boxed{10.8\,\text{m/s}}$$

Find Δt at impact:

$$\Delta t = \frac{20\,\text{m}}{(10.8\,\text{m/s})\cos 53°} = 3.08\,\text{s}$$

Using constant-acceleration equations, find v_y and v_x at impact:

$$v_x = v_{0x} = 6.50\,\text{m/s}$$

and

$$v_y = v_{0y} - g\Delta t = -21\,\text{m/s}$$

Express the velocity at impact in vector form:

$$\vec{v} = \boxed{(6.50\,\text{m/s})\hat{\boldsymbol{i}} + (-21.6\,\text{m/s})\hat{\boldsymbol{j}}}$$

104 ••

Picture the Problem The ball experiences constant acceleration, except during its collision with the wall, so we can use the constant-acceleration equations in the analysis of its motion. Choose a coordinate system with the origin at the point of release, the positive x axis to the right, and the positive y axis upward.

Using a constant-acceleration equation, express the vertical displacement of the ball as a function of Δt:

$$\Delta y = v_{0y}\Delta t - \tfrac{1}{2}g(\Delta t)^2$$

When the ball hits the ground, $\Delta y = -2$ m:

$$-2\,\text{m} = (10\,\text{m/s})\Delta t - \tfrac{1}{2}(9.81\,\text{m/s}^2)(\Delta t)^2$$

Solve for the time of flight:

$$t_{\text{flight}} = \Delta t = 2.22\text{ s}$$

Find the horizontal distance traveled in this time:

$$\Delta x = (10\text{ m/s})\,(2.22\text{ s}) = 22.2\text{ m}$$

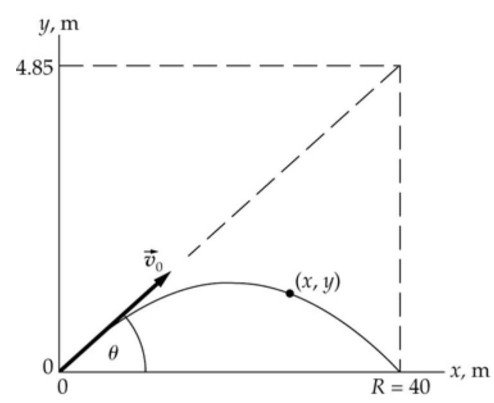
The distance from the wall is:

$$\Delta x - 4\text{ m} = \boxed{18.2\,\text{m}}$$

Hitting Targets and Related Problems

105 •

Picture the Problem In the absence of air resistance, the acceleration of the pebble is constant. Choose the coordinate system shown in the diagram and use constant-acceleration equations to express the coordinates of the pebble in terms of the time into its flight. We can eliminate the parameter t between these equations and solve for the launch velocity of the pebble. We can determine the launch angle from the sighting information and, once the range is known, the time of flight can be found using the horizontal component of the initial velocity.



Referring to the diagram, express θ in terms of the given distances:

$$\theta = \tan^{-1}\left(\frac{4.85\,\text{m}}{40\,\text{m}}\right) = 6.91°$$

Use a constant-acceleration equation to express the horizontal position of the pebble as a function of time:

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$

or, because $x_0 = 0$, $v_{0x} = v_0\cos\theta$, and $a_x = 0$,

$$x = (v_0\cos\theta)t \qquad (1)$$

Use a constant-acceleration equation to express the vertical position of the
pebble as a function of time:

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$

or, because $y_0 = 0$, $v_{0y} = v_0\sin\theta$, and $a_y = -g$,

$$y = (v_0\sin\theta)t - \tfrac{1}{2}gt^2$$

Eliminate the parameter t to obtain:

$$y = (\tan\theta)x - \frac{g}{2v_0^2\cos^2\theta}x^2$$

At impact, $y = 0$ and $x = R$:

$$0 = (\tan\theta)R - \frac{g}{2v_0^2\cos^2\theta}R^2$$

Solve for v_0 to obtain:

$$v_0 = \sqrt{\frac{Rg}{\sin 2\theta}}$$

Substitute numerical values and evaluate v_0:

$$v_0 = \sqrt{\frac{(40\,\text{m})(9.81\,\text{m/s}^2)}{\sin 13.8°}} = \boxed{40.6\,\text{m/s}}$$

Substitute in equation (1) to relate R to t_{flight}:

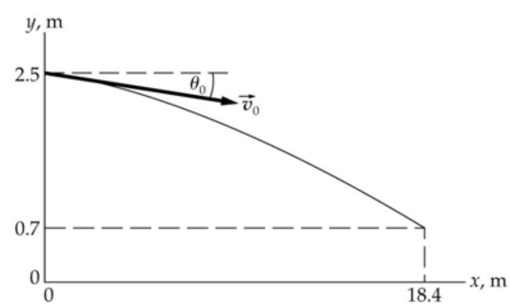
$$R = (v_0\cos\theta)t_{\text{flight}}$$

Solve for and evaluate the time of flight:

$$t_{\text{flight}} = \frac{40\,\text{m}}{(40.6\,\text{m/s})\cos 6.91°} = \boxed{0.992\,\text{s}}$$

***106** ••

Picture the Problem The acceleration of the ball is constant (zero horizontally and –g vertically) and the vertical and horizontal components are independent of each other. Choose the coordinate system shown in the figure and assume that v and t are unchanged by throwing the ball slightly downward.



Express the horizontal displacement of the ball as a function of time:

$$\Delta x = v_{0x}\Delta t + \tfrac{1}{2}a_x(\Delta t)^2$$

or, because $a_x = 0$,
$\Delta x = v_{0x}\Delta t$

Solve for the time of flight if the ball were thrown horizontally:

$$\Delta t = \frac{\Delta x}{v_{0x}} = \frac{18.4\text{ m}}{37.5\text{ m/s}} = 0.491\text{ s}$$

Using a constant-acceleration equation, express the distance the ball would drop (vertical displacement) if it were thrown horizontally:

$$\Delta y = v_{0y}\Delta t + \tfrac{1}{2}a_y(\Delta t)^2$$

or, because $v_{0y} = 0$ and $a_y = -g$,

$$\Delta y = -\tfrac{1}{2}g(\Delta t)^2$$

Substitute numerical values and evaluate Δy:

$$\Delta y = -\tfrac{1}{2}\left(9.81\text{ m/s}^2\right)(0.491\text{ s})^2 = -1.18\text{ m}$$

The ball must drop an additional 0.62 m before it gets to home plate.

$y = (2.5 - 1.18)$ m
= 1.32 m above ground

Calculate the initial downward speed the ball must have to drop 0.62 m in 0.491 s:

$$v_y = \frac{-0.62\text{ m}}{0.491\text{s}} = -1.26\text{ m}$$

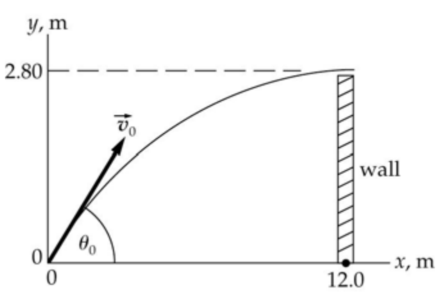
Find the angle with horizontal:

$$\theta = \tan^{-1}\left(\frac{v_y}{v_x}\right) = \tan^{-1}\left(\frac{-1.26\text{ m/s}}{37.5\text{ m/s}}\right) = \boxed{-1.92°}$$

Remarks: One can readily show that $\sqrt{v_x^2 + v_y^2}$ = 37.5 m/s to within 1%; so the assumption that *v* and *t* are unchanged by throwing the ball downward at an angle of 1.93° is justified.

107 ••

Picture the Problem The acceleration of the puck is constant (zero horizontally and –*g* vertically) and the vertical and horizontal components are independent of each other. Choose a coordinate system with the origin at the point of contact with the puck and the coordinate axes as shown in the figure and use constant-acceleration equations to relate the variables v_{0y}, the time *t* to reach the wall, v_{0x}, v_0, and θ_0.



Using a constant-acceleration equation for the motion in the *y* direction, express v_{0y} as a function of the puck's displacement Δy:

$$v_y^2 = v_{0y}^2 + 2a_y\Delta y$$

or, because $v_y = 0$ and $a_y = -g$,

$$0 = v_{0y}^2 - 2g\Delta y$$

Solve for and evaluate v_{0y}:

$$v_{0y}=\sqrt{2g\Delta y}=\sqrt{2(2.80\,\text{m})(9.81\,\text{m/s}^2)}=\boxed{7.41\,\text{m/s}}$$

Find t from the initial velocity in the y direction:

$$t=\frac{v_{0y}}{g}=\frac{7.41\,\text{m/s}}{9.81\,\text{m/s}^2}=\boxed{0.756\,\text{s}}$$

Use the definition of average velocity to find v_{0x}:

$$v_{0x}=v_x=\frac{\Delta x}{t}=\frac{12.0\,\text{m}}{0.756\,\text{s}}=\boxed{15.9\,\text{m/s}}$$

Substitute numerical values and evaluate v_0:

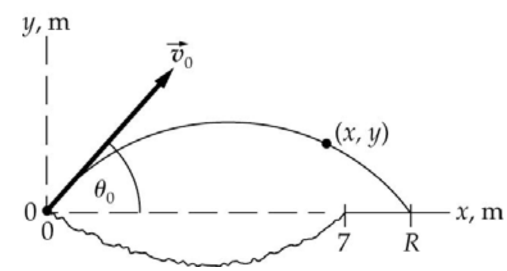
$$v_0=\sqrt{v_{0x}^2+v_{0y}^2}=\sqrt{(15.9\,\text{m/s})^2+(7.41\,\text{m/s})^2}=\boxed{17.5\,\text{m/s}}$$

Substitute numerical values and evaluate θ:

$$\theta=\tan^{-1}\left(\frac{v_{0y}}{v_{0x}}\right)=\tan^{-1}\left(\frac{7.41\,\text{m/s}}{15.9\,\text{m/s}}\right)=\boxed{25.0°}$$

108 ••

Picture the Problem In the absence of air resistance, the acceleration of Carlos and his bike is constant and we can use constant-acceleration equations to express his x and y coordinates as functions of time. Eliminating the parameter t between these equations will yield y as a function of x … an equation we can use to decide whether he can jump the creek bed as well as to find the minimum speed required to make the jump.



(*a*) Use a constant-acceleration equation to express Carlos' horizontal position as a function of time:

$$x=x_0+v_{0x}t+\tfrac{1}{2}a_xt^2$$

or, because $x_0=0$, $v_{0x}=v_0\cos\theta$, and $a_x=0$,

$$x=(v_0\cos\theta)t$$

Use a constant-acceleration equation to express Carlos' vertical position as a function of time:

$$y=y_0+v_{0y}t+\tfrac{1}{2}a_yt^2$$

or, because $y_0=0$, $v_{0y}=v_0\sin\theta$, and $a_y=-g$,

$$y=(v_0\sin\theta)t-\tfrac{1}{2}gt^2$$

Eliminate the parameter t to obtain:

$$y = (\tan\theta)x - \frac{g}{2v_0^2\cos^2\theta}x^2$$

Substitute $y = 0$ and $x = R$ to obtain:

$$0 = (\tan\theta)R - \frac{g}{2v_0^2\cos^2\theta}R^2$$

Solve for and evaluate R:

$$R = \frac{v_0^2}{g}\sin(2\theta_0) = \frac{(11.1\,\text{m/s})^2}{9.81\,\text{m/s}^2}\sin 20°$$
$$= 4.30\,\text{m}$$

$$\boxed{\text{He should apply the brakes!}}$$

(b) Solve the equation we used in the previous step for $v_{0,\text{min}}$:

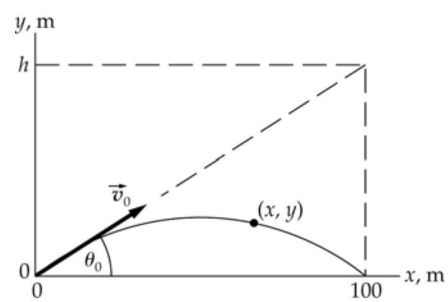
$$v_{0,\text{min}} = \sqrt{\frac{Rg}{\sin(2\theta_0)}}$$

Letting $R = 7$ m, evaluate $v_{0,\text{min}}$:

$$v_{0,\text{min}} = \sqrt{\frac{(7\,\text{m})(9.81\,\text{m/s}^2)}{\sin 20°}}$$
$$= \boxed{14.2\,\text{m/s} = 51.0\,\text{km/h}}$$

109 •••

Picture the Problem In the absence of air resistance, the bullet experiences constant acceleration along its parabolic trajectory. Choose a coordinate system with the origin at the end of the barrel and the coordinate axes oriented as shown in the figure and use constant-acceleration equations to express the x and y coordinates of the bullet as functions of time along its flight path.



Use a constant-acceleration equation to express the bullet's horizontal position as a function of time:

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$

or, because $x_0 = 0$, $v_{0x} = v_0\cos\theta$, and $a_x = 0$,

$$x = (v_0\cos\theta)t$$

Use a constant-acceleration equation to express the bullet's vertical position as a function of time:

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$

or, because $y_0 = 0$, $v_{0y} = v_0\sin\theta$, and $a_y = -g$,

$$y = (v_0\sin\theta)t - \tfrac{1}{2}gt^2$$

Eliminate the parameter t to obtain:

$$y = (\tan\theta)x - \frac{g}{2v_0^2\cos^2\theta}x^2$$

Let $y = 0$ when $x = R$ to obtain:

$$0 = (\tan\theta)R - \frac{g}{2v_0^2\cos^2\theta}R^2$$

Solve for the angle above the horizontal that the rifle must be fired to hit the target:

$$\theta_0 = \tfrac{1}{2}\sin^{-1}\left(\frac{Rg}{v_0^2}\right)$$

Substitute numerical values and evaluate θ_0:

$$\theta_0 = \tfrac{1}{2}\sin^{-1}\left[\frac{(100\,\text{m})(9.81\,\text{m/s}^2)}{(250\,\text{m/s})^2}\right] = 0.450°$$

Note: A second value for θ_0, 89.6° is physically unreasonable.

Referring to the diagram, relate h to θ_0 and solve for and evaluate h:

$$\tan\theta_0 = \frac{h}{100\,\text{m}}$$

and

$$h = (100\,\text{m})\tan(0.450°) = \boxed{0.785\,\text{m}}$$

General Problems

110 •

Picture the Problem The sum and difference of two vectors can be found from the components of the two vectors. The magnitude and direction of a vector can be found from its components.

(*a*) The table to the right summarizes the components of $\vec{A}$ and $\vec{B}$.

Vector	x component (m)	y component (m)
$\vec{A}$	0.707	0.707
$\vec{B}$	0.866	–0.500

(*b*) The table to the right shows the components of $\vec{S}$.

Vector	x component (m)	y component (m)
$\vec{A}$	0.707	0.707
$\vec{B}$	0.866	–0.500
$\vec{S}$	1.57	0.207

Determine the magnitude and direction of $\vec{S}$ from its components:

$$S = \sqrt{S_x^2 + S_y^2} = \boxed{1.59\,\text{m}}$$

and, because $\vec{S}$ is in the 1st

$$\theta_S = \tan^{-1}\left(\frac{S_y}{S_x}\right) = \boxed{7.50°}$$

(*c*) The table to the right shows the components of $\vec{D}$:

Vector	x component (m)	y component (m)
$\vec{A}$	0.707	0.707
$\vec{B}$	0.866	−0.500
$\vec{D}$	−0.159	1.21

Determine the magnitude and direction of $\vec{D}$ from its components:

$$D = \sqrt{D_x^2 + D_y^2} = \boxed{1.22\,\text{m}}$$

and, because $\vec{D}$ is in the 2nd quadrant,

$$\theta_D = \tan^{-1}\left(\frac{D_y}{D_x}\right) = \boxed{97.5°}$$

***111 •**

Picture the Problem A vector quantity can be resolved into its components relative to any coordinate system. In this example, the axes are orthogonal and the components of the vector can be found using trigonometric functions.

The x and y components of $\vec{g}$ are related to g through the sine and cosine functions:

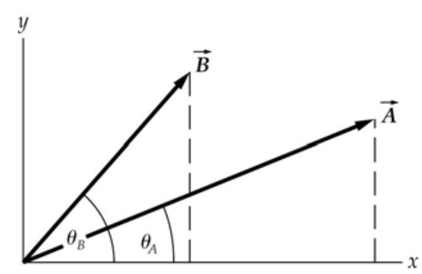
$$g_x = g\sin 30° = \boxed{4.91\,\text{m/s}^2}$$

and

$$g_y = g\cos 30° = \boxed{8.50\,\text{m/s}^2}$$

112 •

Picture the Problem The figure shows two arbitrary, co-planar vectors that (as drawn) do not satisfy the condition that $A/B = A_x/B_x$.



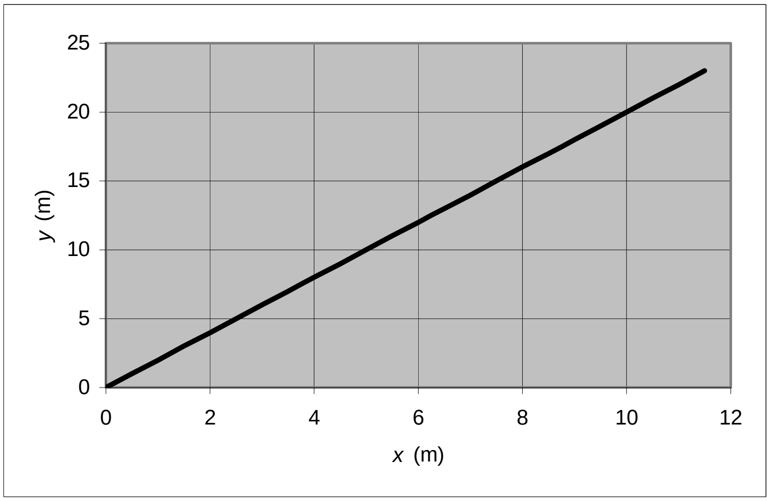
Because $A_x = A\cos\theta_A$ and $B_x = B\cos\theta_B$, $\dfrac{\cos\theta_A}{\cos\theta_B} = 1$ for the condition to be satisfied.

$\therefore$ $A/B = A_x/B_x$ if and only if $\vec{A}$ and $\vec{B}$ are parallel ($\theta_A = \theta_B$) or on opposite sides of the x-axis ($\theta_A = -\theta_B$).

113 •

Picture the Problem We can plot the path of the particle by substituting values for t and evaluating r_x and r_y coordinates of $\vec{r}$. The velocity vector is the time derivative of the position vector.

(*a*) We can assign values to t in the parametric equations $x = (5\text{ m/s})t$ and $y = (10\text{ m/s})t$ to obtain ordered pairs (x, y) that lie on the path of the particle. The path is shown in the following graph:



(*b*) Evaluate $d\vec{\mathbf{r}}/dt$:

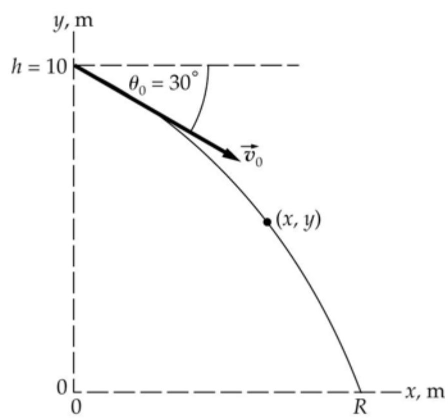
$$\vec{v} = \frac{d\vec{\mathbf{r}}}{dt} = \frac{d}{dt}\left[(5\,\text{m/s})t\,\hat{\boldsymbol{i}} + (10\text{m/s})t\,\hat{\boldsymbol{j}}\right]$$
$$= \boxed{(5\,\text{m/s})\hat{\boldsymbol{i}} + (10\text{m/s})\hat{\boldsymbol{j}}}$$

Use its components to find the magnitude of $\vec{v}$:

$$v = \sqrt{v_x^2 + v_y^2} = \boxed{11.2\,\text{m/s}}$$

114 ••

Picture the Problem In the absence of air resistance, the hammer experiences constant acceleration as it falls. Choose a coordinate system with the origin and coordinate axes as shown in the figure and use constant-acceleration equations to describe the *x* and *y* coordinates of the hammer along its trajectory. We'll use the equation describing the vertical motion to find the time of flight of the hammer and the equation describing the horizontal motion to determine its range.



Using a constant-acceleration equation, express the *x* coordinate of the hammer as a function of time:

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$

or, because $x_0 = 0$, $v_{0x} = v_0\cos\theta_0$, and $a_x = 0$,

$$x = (v_0\cos\theta_0)t$$

Using a constant-acceleration equation, express the *y* coordinate of the hammer as a function of time:

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$

or, because $y_0 = h$, $v_{0y} = v_0\sin\theta$, and $a_y = -g$,

$$y = h + (v_0\sin\theta)t - \tfrac{1}{2}gt^2$$

Substitute numerical values to obtain:

$$y = 10\,\text{m} + (4\,\text{m/s})(\sin 30°)t - \tfrac{1}{2}(9.81\,\text{m/s}^2)t^2$$

Substitute the conditions that exist when the hammer hits the ground:

$$0 = 10\,\text{m} - (4\,\text{m/s})\sin 30°\, t - \tfrac{1}{2}(9.81\,\text{m/s}^2)\, t^2$$

Solve for the time of fall to obtain:

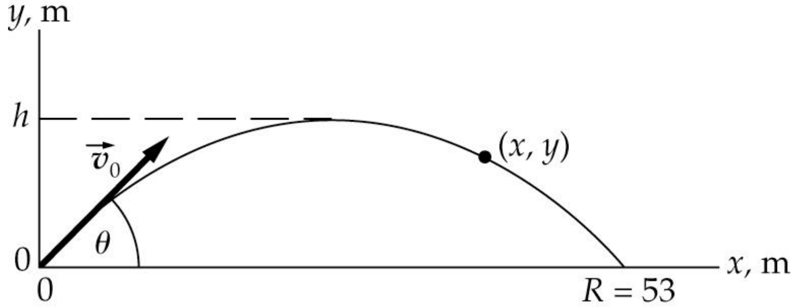
$t = 1.24$ s

Use the x-coordinate equation to find the horizontal distance traveled by the hammer in 1.24 s:

$$R = (4\,\text{m/s})(\cos 30°)(1.24\,\text{s}) = \boxed{4.29\,\text{m}}$$

115 ••

Picture the Problem We'll model Zacchini's flight as though there is no air resistance and, hence, the acceleration is constant. Then we can use constant- acceleration equations to express the x and y coordinates of Zacchini's motion as functions of time. Eliminating the parameter t between these equations will leave us with an equation we can solve for θ. Because the maximum height along a parabolic trajectory occurs (assuming equal launch and landing elevations) occurs at half range, we can use this same expression for y as a function of x to find h.



Use a constant-acceleration equation to express Zacchini's horizontal position as a function of time:

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$

or, because $x_0 = 0$, $v_{0x} = v_0\cos\theta$, and $a_x = 0$,

$$x = (v_0 \cos\theta)t$$

Use a constant-acceleration equation to express Zacchini's vertical position as a function of time:

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$

or, because $y_0 = 0$, $v_{0y} = v_0\sin\theta$, and $a_y = -g$,

$$y = (v_0 \sin\theta)t - \tfrac{1}{2}gt^2$$

Eliminate the parameter t to obtain:

$$y = (\tan\theta)x - \frac{g}{2v_0^2\cos^2\theta}x^2$$

Use Zacchini's coordinates when he lands in a safety net to obtain:

$$0 = (\tan\theta)R - \frac{g}{2v_0^2\cos^2\theta}R^2$$

Solve for his launch angle θ:

$$\theta=\tfrac{1}{2}\sin^{-1}\left(\frac{Rg}{v_0^2}\right)$$

Substitute numerical values and evaluate θ:

$$\theta=\tfrac{1}{2}\sin^{-1}\left[\frac{(53\,\text{m})(9.81\,\text{m/s}^2)}{(24.2\,\text{m/s})^2}\right]=\boxed{31.3°}$$

Use the fact that his maximum height was attained when he was halfway through his flight to obtain:

$$h=(\tan\theta)\frac{R}{2}-\frac{g}{2v_0^2\cos^2\theta}\left(\frac{R}{2}\right)^2$$

Substitute numerical values and evaluate h:

$$h=(\tan 31.3°)\frac{53\,\text{m}}{2}-\frac{9.81\,\text{m/s}^2}{2(24.2\,\text{m/s})^2\cos^2 31.3°}\left(\frac{53\,\text{m}}{2}\right)^2=\boxed{8.06\,\text{m}}$$

116 ••

Picture the Problem Because the acceleration is constant; we can use the constant-acceleration equations in vector form and the definitions of average velocity and average (instantaneous) acceleration to solve this problem.

(*a*) The average velocity is given by:

$$\vec{\boldsymbol{v}}_{\text{av}}=\frac{\Delta\vec{\boldsymbol{r}}}{\Delta t}=\frac{\vec{\boldsymbol{r}}_2-\vec{\boldsymbol{r}}_1}{\Delta t}$$
$$=(3\ \text{m/s})\hat{\boldsymbol{i}}+(-2.5\ \text{m/s})\hat{\boldsymbol{j}}$$

The average velocity can also be expressed as:

$$\vec{\boldsymbol{v}}_{\text{av}}=\frac{\vec{\boldsymbol{v}}_1+\vec{\boldsymbol{v}}_2}{2}$$

and

$$\vec{v}_1=2\vec{v}_{\text{av}}-\vec{v}_2$$

Substitute numerical values to obtain:

$$\vec{\boldsymbol{v}}_1=\boxed{(1\,\text{m/s})\hat{\boldsymbol{i}}+(1\,\text{m/s})\hat{\boldsymbol{j}}}$$

(*b*) The acceleration of the particle is given by:

$$\vec{\boldsymbol{a}}=\frac{\Delta\vec{\boldsymbol{v}}}{\Delta t}=\frac{\vec{\boldsymbol{v}}_2-\vec{\boldsymbol{v}}_1}{\Delta t}$$
$$=\boxed{(2\ \text{m/s}^2)\hat{\boldsymbol{i}}+(-3.5\ \text{m/s}^2)\hat{\boldsymbol{j}}}$$

(*c*) The velocity of the particle as a function of time is:

$$\vec{\boldsymbol{v}}(t)=\vec{\boldsymbol{v}}_1+\vec{\boldsymbol{a}}t=\boxed{[(1\,\text{m/s})+(2\ \text{m/s}^2)t]\hat{\boldsymbol{i}}+[(1\,\text{m/s})+(-3.5\ \text{m/s}^2)t]\hat{\boldsymbol{j}}}$$

(*d*) Express the position vector as a function of time:

$$\vec{\boldsymbol{r}}(t)=\vec{\boldsymbol{r}}_1+\vec{\boldsymbol{v}}_1t+\tfrac{1}{2}\vec{\boldsymbol{a}}t^2$$

Substitute numerical values and evaluate $\vec{r}(t)$:

$$\vec{r}(t) = \boxed{[(4\text{ m}) + (1\text{ m/s})t + (1\text{ m/s}^2)t^2]\hat{i} + [(3\text{ m}) + (1\text{ m/s})t + (-1.75\text{ m/s}^2)t^2]\hat{j}}$$

***117 ••**

Picture the Problem In the absence of air resistance, the steel ball will experience constant acceleration. Choose a coordinate system with its origin at the initial position of the ball, the x direction to the right, and the y direction downward. In this coordinate system $y_0 = 0$ and $a = g$. Letting (x, y) be a point on the path of the ball, we can use constant-acceleration equations to express both x and y as functions of time and, using the geometry of the staircase, find an expression for the time of flight of the ball. Knowing its time of flight, we can find its range and identify the step it strikes first.

The angle of the steps, with respect to the horizontal, is:

$$\theta = \tan^{-1}\left(\frac{0.18\text{ m}}{0.3\text{ m}}\right) = 31.0°$$

Using a constant-acceleration equation, express the x coordinate of the steel ball in its flight:

$$x = x_0 + v_0 t + \tfrac{1}{2}a_y t^2$$

or, because $x_0 = 0$ and $a_y = 0$,

$$x = v_0 t$$

Using a constant-acceleration equation, express the y coordinate of the steel ball in its flight:

$$y = y_0 + v_{0y} t + \tfrac{1}{2}a_y t^2$$

or, because $y_0 = 0$, $v_{0y} = 0$, and $a_y = g$,

$$y = \tfrac{1}{2}gt^2$$

The equation of the dashed line in the figure is:

$$\frac{y}{x} = \tan\theta = \frac{gt}{2v_0}$$

Solve for the flight time:

$$t = \frac{2v_0}{g}\tan\theta$$

Find the x coordinate of the landing position:

$$x = \frac{y}{\tan\theta} = \frac{2v_0^2}{g}\tan\theta$$

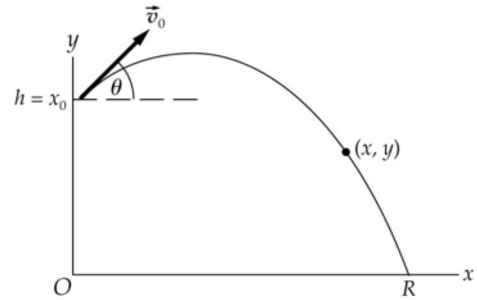
Substitute the angle determined in the first step:

$$x = \frac{2(3\text{ m/s})^2}{9.81\text{ m/s}^2}\tan 31° = 1.10\text{ m}$$

$$\boxed{\text{The first step with } x > 1.10\text{ m is the 4th step.}}$$

118 ••

Picture the Problem Ignoring the influence of air resistance, the acceleration of the ball is constant once it has left your hand and we can use constant-acceleration equations to express the x and y coordinates of the ball. Elimination of the parameter t will yield an equation from which we can determine v_0. We can then use the y equation to express the time of flight of the ball and the x equation to express its range in terms of x_0, v_0, θ and the time of flight.



Use a constant-acceleration equation to express the ball's horizontal position as a function of time:

$$x = x_0 + v_{0x}t + \tfrac{1}{2}a_x t^2$$

or, because $x_0 = 0$, $v_{0x} = v_0\cos\theta$, and $a_x = 0$,

$$x = (v_0 \cos\theta)t \qquad (1)$$

Use a constant-acceleration equation to express the ball's vertical position as a function of time:

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2$$

or, because $y_0 = x_0$, $v_{0y} = v_0\sin\theta$, and $a_y = -g$,

$$y = x_0 + (v_0 \sin\theta)t - \tfrac{1}{2}gt^2 \qquad (2)$$

Eliminate the parameter t to obtain:

$$y = x_0 + (\tan\theta)x - \frac{g}{2v_0^2\cos^2\theta}x^2$$

For the throw while standing on level ground we have:

$$0 = (\tan\theta)x_0 - \frac{g}{2v_0^2\cos^2\theta}x_0^2$$

and

$$x_0 = \frac{v_0^2}{g}\sin 2\theta = \frac{v_0^2}{g}\sin 2(45°) = \frac{v_0^2}{g}$$

Solve for v_0:

$$v_0 = \sqrt{gx_0}$$

At impact equation (2) becomes:

$$0 = x_0 + \left(\sqrt{gx_0}\sin\theta\right)t_{\text{flight}} - \tfrac{1}{2}gt_{\text{flight}}^2$$

Solve for the time of flight:

$$t_{\text{flight}} = \sqrt{\frac{x_0}{g}}\left(\sin\theta + \sqrt{\sin^2\theta + 2}\right)$$

Substitute in equation (1) to express the range of the ball when thrown from an elevation x_0 at an angle θ with the horizontal:

$$R = \left(\sqrt{gx_0}\cos\theta\right)t_{\text{flight}} = \left(\sqrt{gx_0}\cos\theta\right)\sqrt{\frac{x_0}{g}}\left(\sin\theta + \sqrt{\sin^2\theta + 2}\right) = x_0\cos\theta\left(\sin\theta + \sqrt{\sin^2\theta + 2}\right)$$

Substitute θ = 0°, 30°, and 45°:

$$x(0°) = \boxed{1.41x_0}$$

$$x(30°) = \boxed{1.73x_0}$$

and

$$x(45°) = \boxed{1.62x_0}$$

119 •••

Picture the Problem Choose a coordinate system with its origin at the point where the motorcycle becomes airborne and with the positive x direction to the right and the positive y direction upward. With this choice of coordinate system we can relate the x and y coordinates of the motorcycle (which we're treating as a particle) using Equation 3-21.

(*a*) The path of the motorcycle is given by:

$$y(x) = (\tan\theta)x - \left(\frac{g}{2v_0^2\cos^2\theta}\right)x^2$$

For the jump to be successful, $h < y(x)$. Solving for v_0, we find:

$$v_{\min} > \boxed{\frac{x}{\cos\theta}\sqrt{\frac{g}{2(x\tan\theta - h)}}}$$

(*b*) Use the values given to obtain:

$$v_{\min} > \boxed{26.0\,\text{m/s or}\,58.0\,\text{mph}}$$

(*c*) In order for our expression for $v_{\min}$ to be real valued; i.e., to predict values for $v_{\min}$ that are physically meaningful, $x\tan\theta - h > 0$.

$$\therefore\ h_{\max} < x\tan\theta$$

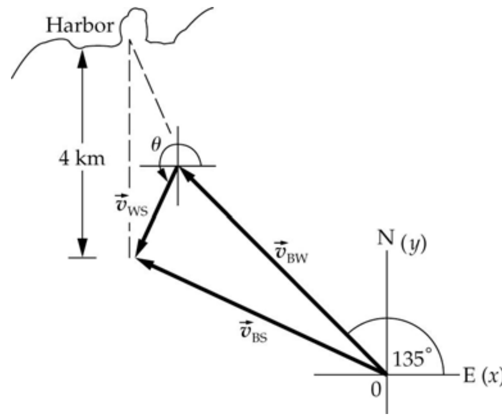
The interpretation is that the bike "falls away" from traveling on a straight-line path due to the free-fall acceleration downwards. No matter what the initial speed of the bike, it must fall a little bit before reaching the other side of the pit.

120 •••

Picture the Problem Let the origin be at the position of the boat when it was engulfed by the fog. Take the x and y directions to be east and north, respectively. Let $\vec{v}_{BW}$ be the velocity of the boat relative to the water, $\vec{v}_{BS}$ be the velocity of the boat relative to the shore, and $\vec{v}_{WS}$ be the velocity of the water with respect to the shore. Then

$$\vec{v}_{BS} = \vec{v}_{BW} + \vec{v}_{WS}.$$

θ is the angle of $\vec{v}_{WS}$ with respect to the x (east) direction.



(*a*) Find the position vector for the boat at $t = 3$ h:

$$\vec{r}_{boat} = \{(32\text{ km})(\cos 135°)t\}\hat{i} + \{(32\text{ km})(\sin 135°)t - 4\text{ km}\}\hat{j}$$
$$= \{(-22.6\text{ km})t\}\hat{i} + \{(22.6\text{ km})t - 4\text{ km}\}\hat{j}$$

Find the coordinates of the boat at $t = 3$ h:

$$r_x = [(10\text{ km/h})\cos 135° + v_{WS}\cos\theta](3\text{ h})$$
and
$$r_y = [(10\text{ km/h})\sin 135° + v_{WS}\sin\theta](3\text{ h})$$

Simplify the expressions involving r_x and r_y and equate these simplified expressions to the x and y components of the position vector of the boat:

$$3v_{WS}\cos\theta = -1.41\text{ km/h}$$
and
$$3v_{WS}\sin\theta = -2.586\text{ km/h}$$

Divide the second of these equations by the first to obtain:

$$\tan\theta = \frac{-2.586\text{ km}}{-1.41\text{ km}}$$
or
$$\theta = \tan^{-1}\left(\frac{-2.586\text{ km}}{-1.41\text{ km}}\right) = 61.4° \text{ or } 241.4°$$

Because the boat has drifted south, use $\theta = 241.4°$ to obtain:

$$v_{WS} = \frac{v_x}{\cos\theta} = \frac{-\frac{1.41\text{ km/h}}{3}}{\cos(241.4°)}$$
$$= \boxed{0.982\text{ km/h at } \theta = 241.4°}$$

(*b*) Letting ϕ be the angle between east and the proper heading for the boat, express the components of the velocity of the boat with respect to the shore:

$$v_{BS,x} = (10\text{ km/h})\cos\phi + (0.982\text{ km/h})\cos(241.3°)$$

$$v_{BS,y} = (10\text{ km/h})\sin\phi + (0.982\text{ km/h})\sin(241.3°)$$

For the boat to travel northwest:

$$v_{BS,x} = -v_{BS,y}$$

Substitute the velocity components, square both sides of the equation, and simplify the expression to obtain the equations:

$$\sin\phi + \cos\phi = 0.133,$$
$$\sin^2\phi + \cos^2\phi + 2\sin\phi\cos\phi = 0.0177,$$
and
$$1 + \sin(2\phi) = 0.0177$$

Solve for ϕ:

$$\phi = 129.6° \text{ or } 140.4°$$

Because the current pushes south, the boat must head more northerly than 135°:

Using 129.6°, the correct heading is $\boxed{39.6° \text{ west of north}}$.

(*c*) Find v_{BS}:

$$v_{BS,x} = -6.84\text{ km/h}$$
and
$$v_{BS} = v_{Bx}/\cos 135° = 9.68\text{ km/h}$$

To find the time to travel 32 km, divide the distance by the boat's actual speed:

$$t = (32\text{ km})/(9.68\text{ km/h}) = \boxed{3.31\text{ h} = 3\text{ h } 18\text{ min}}$$

***121 ••**

Picture the Problem In the absence of air resistance, the acceleration of the projectile is constant and the equation of a projectile for equal initial and final elevations, which was derived from the constant-acceleration equations, is applicable. We can use the equation giving the range of a projectile for equal initial and final elevations to evaluate the ranges of launches that exceed or fall short of 45° by the same amount.

Express the range of the projectile as a function of its initial speed and angle of launch:

$$R = \frac{v_0^2}{g}\sin 2\theta_0$$

Let $\theta_0 = 45° \pm \theta$:

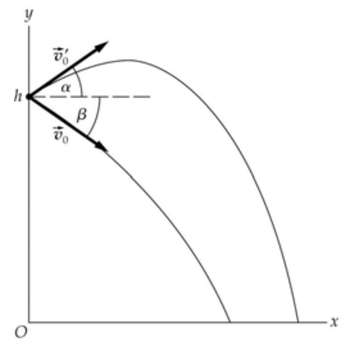
$$R = \frac{v_0^2}{g}\sin(90° \pm 2\theta) = \frac{v_0^2}{g}\cos(\pm 2\theta)$$

Because $\cos(-\theta) = \cos(+\theta)$ (the cosine function is an *even* function):

$$\boxed{R(45° + \theta) = R(45° - \theta)}$$

122 ••

Picture the Problem In the absence of air resistance, the acceleration of both balls is that due to gravity and the horizontal and vertical motions are independent of each other. Choose a coordinate system with the origin at the base of the cliff and the coordinate axes oriented as shown and use constant-acceleration equations to relate the *x* and *y* components of the ball's speed.



Independently of whether a ball is thrown upward at the angle α or downward at β, the vertical motion is described by:

$$v_y^2 = v_{0y}^2 + 2a\Delta y$$
$$= v_{0y}^2 - 2gh$$

The horizontal component of the motion is given by:

$v_x = v_{0x}$

Find v at impact from its components:

$$v = \sqrt{v_x^2 + v_y^2} = \sqrt{v_{0x}^2 + v_{0y}^2 - 2gh}$$
$$= \boxed{\sqrt{v_0^2 - 2gh}}$$

Chapter 4
Newton's Laws

Conceptual Problems

***1** ••

Determine the Concept A reference frame in which the law of inertia holds is called an inertial reference frame.

If an object with no net force acting on it is at rest or is moving with a constant speed in a straight line (i.e., with constant velocity) relative to the reference frame, then the reference frame is an inertial reference frame. Consider sitting at rest in an accelerating train or plane. The train or plane is not an inertial reference frame even though you are at rest relative to it. In an inertial frame, a dropped ball lands at your feet. You are in a noninertial frame when the driver of the car in which you are riding steps on the gas and you are pushed back into your seat.

2 ••

Determine the Concept A reference frame in which the law of inertia holds is called an inertial reference frame. A reference frame with acceleration *a* relative to the initial frame, and with *any* velocity relative to the initial frame, is inertial.

3 •

Determine the Concept No. If the net force acting on an object is zero, its acceleration is zero. The only conclusion one can draw is that the *net* force acting on the object is zero.

***4** •

Determine the Concept An object accelerates when a *net* force acts on it. The fact that an object is accelerating tells us nothing about its velocity other than that it is always changing.

Yes, the object must have an acceleration relative to the inertial frame of reference. According to Newton's 1st and 2nd laws, an object must accelerate, relative to any inertial reference frame, in the direction of the net force. If there is ″only a single nonzero force,″ then this force is the net force.

Yes, the object's velocity may be momentarily zero. During the period in which the force is acting, the object may be momentarily at rest, but its velocity cannot remain zero because it must continue to accelerate. Thus, its velocity is always changing.

5 •

Determine the Concept No. Predicting the direction of the subsequent motion correctly requires knowledge of the initial velocity as well as the acceleration. While the acceleration can be obtained from the net force through Newton's 2nd law, the velocity can only be obtained by integrating the acceleration.

6 •

Determine the Concept An object in an inertial reference frame accelerates if there is a *net* force acting on it. Because the object is moving at constant velocity, the net force acting on it is zero. $\boxed{(c)\text{ is correct.}}$

7 •

Determine the Concept The mass of an object is an intrinsic property of the object whereas the weight of an object depends directly on the local gravitational field. Therefore, the mass of the object would not change and $w_{\text{grav}} = mg_{\text{local}}$. Note that if the gravitational field is zero then the gravitational force is also zero.

***8** •

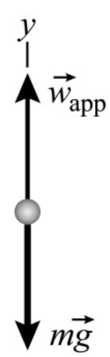
Determine the Concept If there is a force on her in addition to the gravitational force, she will experience an additional acceleration relative to her space vehicle that is proportional to the net force required producing that acceleration and inversely proportional to her mass.

She could do an experiment in which she uses her legs to push off from the wall of her space vehicle and measures her acceleration and the force exerted by the wall. She could calculate her mass from the ratio of the force exerted by the wall to the acceleration it produced.

***9** •

Determine the Concept One's apparent weight is the reading of a scale in one's reference frame.

Imagine yourself standing on a scale that, in turn, is on a platform accelerating upward with an acceleration *a*. The free-body diagram shows the force the gravitational field exerts on you, $m\vec{g}$, and the force the scale exerts on you, $\vec{w}_{\text{app}}$. The scale reading (the force the scale exerts on you) is your apparent weight.



Choose the coordinate system shown in the free-body diagram and apply $\sum \vec{F} = m\vec{a}$ to the scale:

$$\sum F_y = w_{\text{app}} - mg = ma_y$$

or

$$w_{\text{app}} = mg + ma_y$$

So, your apparent weight would be greater than your true weight when observed from a reference frame that is accelerating upward. That is, when the surface on which you are standing has an acceleration *a* such that a_y is positive: $\boxed{a_y > 0}$.

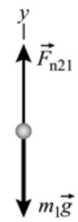
10 ••

Determine the Concept Newton's 2nd law tells us that forces produce *changes* in the velocity of a body. If two observers pass each other, each traveling at a constant velocity, each will experience no net force acting on them, and so each will feel as if he or she is standing still.

11 •

Determine the Concept Neither block is accelerating so the net force on each block is zero. Newton's 3rd law states that objects exert equal and opposite forces on each other.

(a) and (b) Draw the free-body diagram for the forces acting on the block of mass m_1:



Apply $\sum \vec{F} = m\vec{a}$ to the block 1:

$$\sum F_y = F_{n21} - m_1 g = m_1 a_1$$

or, because $a_1 = 0$,

$$F_{n21} - m_1 g = 0$$

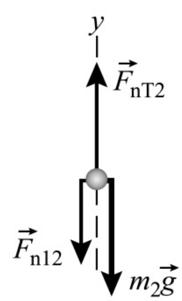
Therefore, the magnitude of the force that block 2 exerts on block 1 is given by:

$$F_{n21} = \boxed{m_1 g}$$

From Newton's 3rd law of motion we know that the force that block 1 exerts on block 2 is equal to, but opposite in direction, the force that block 2 exerts on block 1.

$$\vec{F}_{n21} = -\vec{F}_{n12} \Rightarrow F_{n12} = \boxed{m_1 g}$$

(c) and (d) Draw the free-body diagram for the forces acting on block 2:



Apply $\sum \vec{F} = m\vec{a}$ to block 2:

$$\sum F_{2y} = F_{nT2} - F_{n12} - m_2 g = m_2 a_2$$

or, because $a_2 = 0$,

$$F_{nT2} = F_{nT2} + m_2 g = m_1 g + m_2 g$$
$$= (m_1 + m_2)g$$

and the normal force that the table exerts on body 2 is

$$F_{nT2} = \boxed{(m_1 + m_2)g}$$

From Newton's 3rd law of motion we know that the force that block 2 exerts on the table is equal to, but opposite in direction, the force that the table exerts on block 2.

$$\vec{F}_{nT2} = -\vec{F}_{n2T} \Rightarrow F_{n2T} = \boxed{(m_1 + m_2)g}$$

***12** •

(*a*) True. By definition, action-reaction force pairs cannot act on the same object.

(*b*) False. Action equals reaction independent of any motion of the two objects.

13 •

Determine the Concept Newton's 3rd law of motion describes the interaction between the man and his less massive son. According to the 3rd law description of the interaction of two objects, these are action-reaction forces and therefore must be equal in magnitude. $\boxed{(b)\text{ is correct.}}$

14 •

Determine the Concept According to Newton's 3rd law the reaction force to a force exerted by object A on object B is the force exerted by object B on object A. The bird's weight is a gravitational field force exerted by the earth on the bird. Its reaction force is the gravitational force the bird exerts on the earth. $\boxed{(b)\text{ is correct.}}$

15 •

Determine the Concept We know from Newton's 3rd law of motion that the reaction to the force that the bat exerts on the ball is the force the ball exerts on the bat and is equal in magnitude but oppositely directed. The action-reaction pair consists of the force with which the bat hits the ball and the force the ball exerts on the bat. These forces are equal in magnitude, act in opposite directions. $\boxed{(c)\text{ is correct.}}$

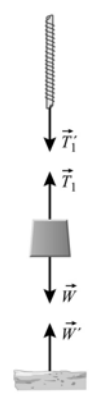
16 •

Determine the Concept The statement of Newton's 3rd law given in the problem is not complete. It is important to remember that the action and reaction forces act on different bodies. The reaction force does not cancel out because it does not act on the same body as the external force.

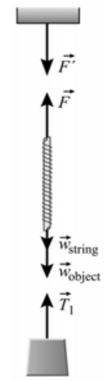
***17** •

Determine the Concept The force diagrams will need to include the ceiling, string, object, and earth if we are to show all of the reaction forces as well as the forces acting on the object.

(*a*) The forces acting on the 2.5-kg object are its weight $\vec{W}$, and the tension $\vec{T}_1$, in the string. The reaction forces are $\vec{W}\,'$ acting on the earth and $\vec{T}_1\,'$ acting on the string.



(b) The forces acting on the string are its weight, the weight of the object, and $\vec{F}$, the force exerted by the ceiling. The reaction forces are $\vec{T}_1$ acting on the string and $\vec{F}\,'$ acting on the ceiling.



18 •

Determine the Concept Identify the objects in the block's environment that are exerting forces on the block and then decide in what directions those forces must be acting if the block is sliding *down* the inclined plane.

Because the incline is frictionless, the force the incline exerts on the block must be normal to the surface. The second object capable of exerting a force on the block is the earth and its force; the weight of the block acts directly downward. The magnitude of the normal force is less than that of the weight because it supports only a portion of the weight. $\boxed{\text{The forces shown in FBD } (c) \text{ satisfy these conditions.}}$

19 •

Determine the Concept In considering these statements, one needs to decide whether they are consistent with Newton's laws of motion. A good strategy is to try to think of a counterexample that would render the statement false.

(a) True. If there are no forces acting on an object, the *net* force acting on it must be zero and, hence, the acceleration must be zero.

(b) False. Consider an object moving with constant velocity on a frictionless horizontal surface. While the *net* force acting on it is zero (it is not accelerating), gravitational and normal forces are acting on it.

(c) False. Consider an object that has been thrown vertically upward. While it is still rising, the direction of the gravitational force acting on it is downward.

(d) False. The mass of an object is an intrinsic property that is independent of its location (the gravitational field in which it happens to be situated).

20 •

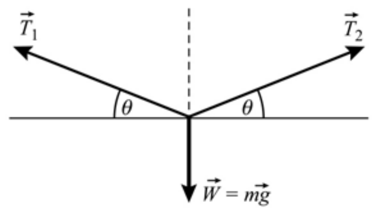
Determine the Concept In considering these alternatives, one needs to decide which alternatives are consistent with Newton's 3rd law of motion. According to Newton's 3rd law, the magnitude of the gravitational force exerted by her body on the earth is equal and opposite to the force exerted by the earth on her. $\boxed{(a) \text{ is correct.}}$

***21 •**

Determine the Concept In considering these statements, one needs to decide whether they are consistent with Newton's laws of motion. In the absence of a *net* force, an object moves with constant velocity. $\boxed{(d) \text{ is correct.}}$

22 •

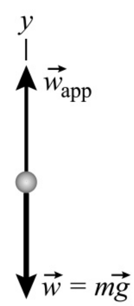
Determine the Concept Draw the free-body diagram for the towel. Because the towel is hung at the center of the line, the magnitudes of $\vec{T}_1$ and $\vec{T}_2$ are the same.



No. To support the towel, the tension in the line must have a vertical component equal to the towel's weight. Thus $\theta > 0$.

23 •

Determine the Concept The free-body diagram shows the forces acting on a person in a descending elevator. The upward force exerted by the scale on the person, $\vec{w}_{app}$, is the person's apparent weight.



Apply $\sum F_y = ma_y$ to the person and solve for w_{app}:

$$w_{app} - mg = ma_y$$

or

$$w_{app} = mg + ma_y = m(g + a_y)$$

$$\boxed{\begin{array}{l}\text{Because } w_{app} \text{ is independent of } v, \\ \text{the velocity of the elevator has} \\ \text{no effect on the person's apparent} \\ \text{weight.}\end{array}}$$

Remarks: Note that a nonconstant velocity will alter the apparent weight.

Estimation and Approximation

24 ••

Picture the Problem Assuming a stopping distance of 25 m and a mass of 80 kg, use Newton's 2nd law to determine the force exerted by the seat belt.

The force the seat belt exerts on the driver is given by:

$F_{net} = ma$, where m is the mass of the driver.

Using a constant-acceleration equation, relate the velocity of the car to its stopping distance and acceleration:

$$v^2 = v_0^2 + 2a\Delta x$$

or, because $v = 0$,

$$-v_0^2 = 2a\Delta x$$

Solve for a:

$$a = \frac{-v_0^2}{2\Delta x}$$

Substitute numerical values and evaluate a:

$$a = -\frac{\left(90\,\frac{\text{km}}{\text{h}} \times \frac{1\,\text{h}}{3600\,\text{s}} \times \frac{10^3\,\text{m}}{\text{km}}\right)^2}{2(25\,\text{m})} = -12.5\,\text{m/s}^2$$

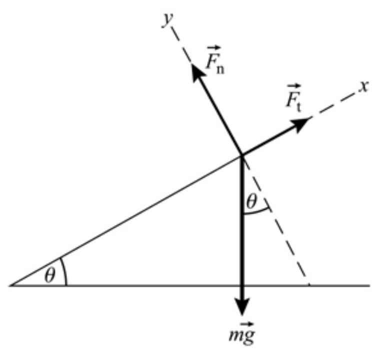
Substitute for a and evaluate F_{net}:

$$F_{\text{net}} = (80\,\text{kg})(-12.5\,\text{m/s}^2) = \boxed{-1.00\,\text{kN}}$$

F_{net} is negative because it is opposite the direction of motion.

***25** •••

Picture the Problem The free-body diagram shows the forces acting on you and your bicycle as you are either ascending or descending the grade. The magnitude of the normal force acting on you and your bicycle is equal to the component of your weight in the *y* direction and the magnitude of the tangential force is the *x* component of your weight. Assume a combined mass (you plus your bicycle) of 80 kg.



(*a*) Apply $\sum F_y = ma_y$ to you and your bicycle and solve for F_n:

$F_n - mg\cos\theta = 0$, because there is no acceleration in the *y* direction.

$\therefore F_n = mg\cos\theta$

Determine θ from the information concerning the grade:

$\tan\theta = 0.08$

and

$\theta = \tan^{-1}(0.08) = 4.57°$

Substitute to determine F_n:

$$F_n = (80\text{ kg})(9.81\text{ m/s}^2)\cos 4.57° = \boxed{782\,\text{N}}$$

Apply $\sum F_x = ma_x$ to you and your bicycle and solve for F_t, the tangential force exerted by the road on the wheels:

$F_t - mg\sin\theta = 0$, because there is no acceleration in the *x* direction.

Evaluate F_t:

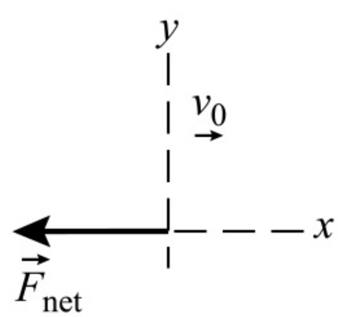
$$F_t = (80\text{ kg})(9.81\text{ m/s}^2)\sin 4.57° = \boxed{62.6\text{ N}}$$

(*b*) Because there is no acceleration, the forces are the same going up and going down the incline.

Newton's First and Second Laws: Mass, Inertia, and Force

26 •

Picture the Problem The acceleration of the particle can be found from the stopping distance by using a constant-acceleration equation. The mass of the particle and its acceleration are related to the net force through Newton's second law of motion. Choose a coordinate system in which the direction the particle is moving is the positive x direction and apply $\vec{F}_{net} = m\vec{a}$.



Use Newton's 2nd law to relate the mass of the particle to the net force acting on it and its acceleration:

$$m = \frac{F_{net}}{a_x}$$

Because the force is constant, use a constant-acceleration equation with $v_x = 0$ to determine a:

$$v_x^2 = v_{0x}^2 + 2a_x\Delta x$$

and

$$a_x = \frac{-v_{0x}^2}{2\Delta x}$$

Substitute to obtain:

$$m = \frac{2\Delta x F_{net}}{v_{0x}^2}$$

Substitute numerical values and evaluate m:

$$m = \frac{2(62.5\text{ m})(15.0\text{ N})}{(25.0\text{ m/s})^2} = 3.00\text{ kg}$$

and $\boxed{(b)\text{ is correct.}}$

27 •

Picture the Problem The acceleration of the object is related to its mass and the *net* force acting on it by $F_{net} = F_0 = ma$.

(*a*) Use Newton's 2nd law of motion to calculate the acceleration of the object:

$$a = \frac{F_{net}}{m} = \frac{2F_0}{m}$$

$$= 2(3\text{ m/s}^2) = \boxed{6.00\text{ m/s}^2}$$

(*b*) Let the subscripts 1 and 2 distinguish the two objects. The ratio of the two masses is found from Newton's 2nd law:

$$\frac{m_2}{m_1}=\frac{F_0/a_2}{F_0/a_1}=\frac{a_1}{a_2}=\frac{3\,\text{m/s}^2}{9\,\text{m/s}^2}=\boxed{\frac{1}{3}}$$

(*c*) The acceleration of the two-mass system is the net force divided by the total mass $m = m_1 + m_2$:

$$a=\frac{F_{\text{net}}}{m}=\frac{F_0}{m_1+m_2}$$
$$=\frac{F_0/m_1}{1+m_2/m_1}=\frac{a_1}{1+1/3}$$
$$=\tfrac{3}{4}a_1=\boxed{2.25\,\text{m/s}^2}$$

28 •

Picture the Problem The acceleration of an object is related to its mass and the *net* force acting on it by $F_{\text{net}}=ma$. Let m be the mass of the ship, a_1 be the acceleration of the ship when the net force acting on it is F_1, and a_2 be its acceleration when the net force is $F_1 + F_2$.

Using Newton's 2nd law, express the net force acting on the ship when its acceleration is a_1:

$$F_1 = ma_1$$

Express the net force acting on the ship when its acceleration is a_2:

$$F_1 + F_2 = ma_2$$

Divide the second of these equations by the first and solve for the ratio F_2/F_1:

$$\frac{F_1+F_2}{F_1}=\frac{ma_1}{ma_2}$$

and

$$\frac{F_2}{F_1}=\frac{a_2}{a_1}-1$$

Substitute for the accelerations to determine the ratio of the accelerating forces and solve for F_2:

$$\frac{F_2}{F_1}=\frac{(16\,\text{km/h})/(10\,\text{s})}{(4\,\text{km/h})/(10\,\text{s})}-1=3$$

or

$$F_2=\boxed{3F_1}$$

***29** ••

Picture the Problem Because the deceleration of the bullet is constant, we can use a constant-acceleration equation to determine its acceleration and Newton's 2nd law of motion to find the average resistive force that brings it to a stop.

Apply $\sum\vec{F}=m\vec{a}$ to express the force exerted on the bullet by the wood:

$$F_{\text{wood}} = ma$$

Using a constant-acceleration

$$v^2=v_0^2+2a\Delta x$$

equation, express the final velocity of the bullet in terms of its acceleration and solve for the acceleration:

and

$$a=\frac{v^2-v_0^2}{2\Delta x}=\frac{-v_0^2}{2\Delta x}$$

Substitute to obtain:

$$F_{\text{wood}}=-\frac{mv_0^2}{2\Delta x}$$

Substitute numerical values and evaluate F_{wood}:

$$F_{\text{wood}}=-\frac{(1.8\times10^{-3}\text{ kg})(500\text{ m/s})^2}{2(0.06\text{ m})}$$

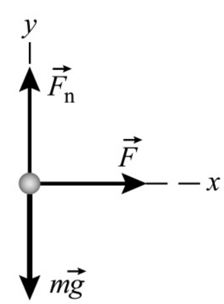
$$=\boxed{-3.75\text{ kN}}$$

where the negative sign means that the direction of the force is opposite the velocity.

***30 ••**

Picture the Problem The pictorial representation summarizes what we know about the motion. We can find the acceleration of the cart by using a constant-acceleration equation.

The free-body diagram shows the forces acting on the cart as it accelerates along the air track. We can determine the net force acting on the cart using Newton's 2nd law and our knowledge of its acceleration.



(*a*) Apply $\sum F_x = ma_x$ to the cart to obtain an expression for the net force F:

$$F = ma$$

Using a constant-acceleration equation, relate the displacement of the cart to its acceleration, initial speed, and travel time:

$$\Delta x = v_0\Delta t+\tfrac{1}{2}a(\Delta t)^2$$

or, because $v_0 = 0$,

$$\Delta x = \tfrac{1}{2}a(\Delta t)^2$$

Solve for *a*:

$$a = \frac{2\Delta x}{(\Delta t)^2}$$

Substitute for *a* in the force equation to obtain:

$$F = m\frac{2\Delta x}{(\Delta t)^2} = \frac{2m\Delta x}{(\Delta t)^2}$$

Substitute numerical values and evaluate *F*:

$$F = \frac{2(0.355\,\text{kg})(1.5\,\text{m})}{(4.55\,\text{s})^2} = \boxed{0.0514\,\text{N}}$$

(*b*) Using a constant-acceleration equation, relate the displacement of the cart to its acceleration, initial speed, and travel time:

$$\Delta x = v_0\Delta t + \tfrac{1}{2}a'(\Delta t)^2$$

or, because $v_0 = 0$,

$$\Delta x = \tfrac{1}{2}a'(\Delta t)^2$$

Solve for Δt:

$$\Delta t = \sqrt{\frac{2\Delta x}{a'}}$$

If we assume that air resistance is negligible, the net force on the cart is still 0.0514 N and its acceleration is:

$$a' = \frac{0.0514\,\text{N}}{0.722\,\text{kg}} = 0.0713\,\text{m/s}^2$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \sqrt{\frac{2(1.5\,\text{m})}{0.0713\,\text{m/s}^2}} = \boxed{6.49\,\text{s}}$$

31 •

Picture the Problem The acceleration of an object is related to its mass and the *net* force acting on it according to $\vec{F}_{\text{net}} = m\vec{a}$. Let *m* be the mass of the object and choose a coordinate system in which the direction of $2F_0$ in (*b*) is the positive *x* and the direction of the left-most F_0 in (a) is the positive *y* direction. Because both force and acceleration are vector quantities, find the resultant force in each case and then find the resultant acceleration.

(*a*) Calculate the acceleration of the object from Newton’s 2nd law of motion:

$$\vec{a} = \frac{\vec{F}_{\text{net}}}{m}$$

Express the net force acting on the object:

$$\vec{F}_{\text{net}} = F_x\hat{i} + F_y\hat{j} = F_0\hat{i} + F_0\hat{j}$$

and

Find the magnitude and direction of this net force:

$$F_{\text{net}} = \sqrt{F_x^2 + F_y^2} = \sqrt{2}F_0$$

and

$$\theta = \tan^{-1}\left(\frac{F_y}{F_x}\right) = \tan^{-1}\left(\frac{F_0}{F_0}\right) = 45°$$

Use this result to calculate the magnitude and direction of the acceleration:

$$a = \frac{F_{\text{net}}}{m} = \frac{\sqrt{2}F_0}{m} = \sqrt{2}a_0$$
$$= \sqrt{2}\left(3\,\text{m/s}^2\right)$$
$$= \boxed{4.24\,\text{m/s}^2 \text{ @ } 45.0° \text{ from each force.}}$$

(*b*) Calculate the acceleration of the object from Newton's 2nd law of motion:

$$\vec{a} = \vec{F}_{\text{net}}/m$$

Express the net force acting on the object:

$$\vec{F}_{\text{net}} = F_x\hat{i} + F_y\hat{j}$$
$$= \left(-F_0 \sin 45°\right)\hat{i} + \left(2F_0 + F_0 \cos 45°\right)\hat{j}$$

Find the magnitude and direction of this net force:

$$F_{\text{net}} = \sqrt{F_x^2 + F_y^2} = \sqrt{\left(-F_0 \sin 45°\right)^2 + \left(2F_0 + F_0 \cos 45°\right)^2} = 2.80F_0$$

and

$$\theta = \tan^{-1}\left(\frac{F_y}{F_x}\right) = \tan^{-1}\left(\frac{2F_0 + F_0 \cos 45°}{-F_0 \sin 45°}\right) = -75.4°$$
$$= 14.6° \text{ from } 2\vec{F}_0$$

Use this result to calculate the magnitude and direction of the acceleration:

$$a = \frac{F_{\text{net}}}{m} = 2.80\frac{F_0}{m} = 2.80a_0$$
$$= 2.80\left(3\,\text{m/s}^2\right)$$
$$= \boxed{8.40\,\text{m/s}^2 \text{ @ } 14.6° \text{ from } 2\vec{F}_0}$$

32 •

Picture the Problem The acceleration of an object is related to its mass and the *net* force acting on it according to $\vec{a} = \vec{F}_{\text{net}}/m$.

Apply $\vec{a} = \vec{F}_{\text{net}}/m$ to the object to obtain:

$$\vec{a} = \frac{\vec{F}_{\text{net}}}{m} = \frac{(6\,\text{N})\hat{i} - (3\,\text{N})\hat{j}}{1.5\,\text{kg}}$$
$$= \boxed{\left(4.00\,\text{m/s}^2\right)\hat{i} - \left(2.00\,\text{m/s}^2\right)\hat{j}}$$

Find the magnitude of $\vec{a}$:

$$a = \sqrt{a_x^2 + a_y^2}$$
$$= \sqrt{\left(4.00\,\text{m/s}^2\right)^2 + \left(2.00\,\text{m/s}^2\right)^2}$$
$$= \boxed{4.47\,\text{m/s}^2}$$

33 •

Picture the Problem The mass of the particle is related to its acceleration and the *net* force acting on it by Newton’s 2nd law of motion. Because the force is constant, we can use constant-acceleration formulas to calculate the acceleration. Choose a coordinate system in which the positive *x* direction is the direction of motion of the particle.

The mass is related to the net force and the acceleration by Newton’s 2nd law:

$$m = \frac{\sum \vec{F}}{\vec{a}} = \frac{F_x}{a_x}$$

Because the force is constant, the acceleration is constant. Use a constant-acceleration equation to find the acceleration:

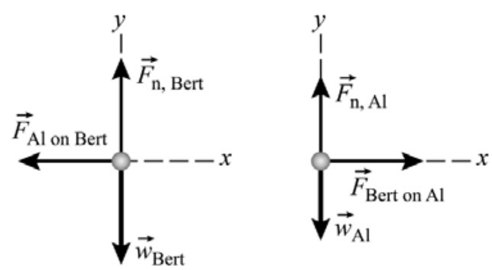
$$\Delta x = v_{0x}t + \tfrac{1}{2}a_x(\Delta t)^2\text{, where } v_{0x} = 0,$$
so
$$a_x = \frac{2\Delta x}{(\Delta t)^2}$$

Substitute this result into the first equation and solve for and evaluate the mass *m* of the particle:

$$m = \frac{F_x}{a_x} = \frac{F_x(\Delta t)^2}{2\Delta x} = \frac{(12\,\text{N})(6\,\text{s})^2}{2(18\,\text{m})}$$
$$= \boxed{12.0\,\text{kg}}$$

***34** •

Picture the Problem The speed of either Al or Bert can be obtained from their accelerations; in turn, they can be obtained from Newtons 2nd law applied to each person. The free-body diagrams to the right show the forces acting on Al and Bert. The forces that Al and Bert exert on each other are action-and-reaction forces.



(*a*) Apply $\sum F_x = ma_x$ to Bert and solve for his acceleration:

$$-F_{\text{Al on Bert}} = m_{\text{Bert}}a_{\text{Bert}}$$
$$a_{\text{Bert}} = \frac{-F_{\text{Al on Bert}}}{m_{\text{Bert}}} = \frac{-20\,\text{N}}{100\,\text{kg}}$$
$$= -0.200\,\text{m/s}^2$$

Using a constant-acceleration equation, relate Bert’s speed to his initial speed, speed after 1.5 s, and acceleration and solve for his speed at the end of 1.5 s:

$$v = v_0 + a\Delta t$$
$$= 0 + (-0.200\,\text{m/s}^2)(1.5\,\text{s})$$
$$= \boxed{-0.300\,\text{m/s}}$$

(*b*) From Newton's 3rd law, an equal but oppositely directed force acts on Al while he pushes Bert. Because the ice is frictionless, Al speeds off in the opposite direction. Apply Newton's 2nd law to the forces acting on Al and solve for his acceleration:

$$\sum F_{x,\mathrm{Al}} = F_{\mathrm{Bert\,on\,Al}} = m_{\mathrm{Al}} a_{\mathrm{Al}}$$

and

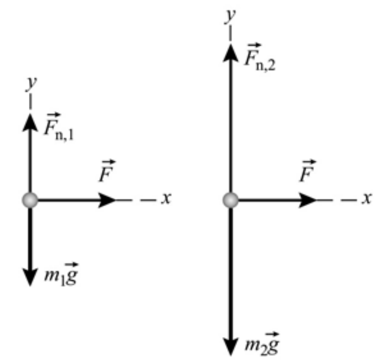
$$a_{\mathrm{Al}} = \frac{F_{\mathrm{Bert\,on\,Al}}}{m_{\mathrm{Al}}} = \frac{20\,\mathrm{N}}{80\,\mathrm{kg}} = 0.250\,\mathrm{m/s^2}$$

Using a constant-acceleration equation, relate Al's speed to his initial speed, speed after 1.5 s, and acceleration; solve for his speed at the end of 1.5 s:

$$v = v_0 + a\Delta t = 0 + (0.250\,\mathrm{m/s^2})(1.5\,\mathrm{s}) = \boxed{0.375\,\mathrm{m/s}}$$

35 •

Picture the Problem The free-body diagrams show the forces acting on the two blocks. We can apply Newton's second law to the forces acting on the blocks and eliminate F to obtain a relationship between the masses. Additional applications of Newton's 2nd law to the sum and difference of the masses will lead us to values for the accelerations of these combinations of mass.



(*a*) Apply $\sum F_x = ma_x$ to the two blocks:

$$\sum F_{x,1} = F = m_1 a_1$$

and

$$\sum F_{x,2} = F = m_2 a_2$$

Eliminate F between the two equations and solve for m_2:

$$m_2 = \frac{a_1}{a_2} m_1 = \frac{12\,\mathrm{m/s^2}}{3\,\mathrm{m/s^2}} m_1 = 4m_1$$

Express and evaluate the acceleration of an object whose mass is $m_2 - m_1$ when the net force acting on it is F:

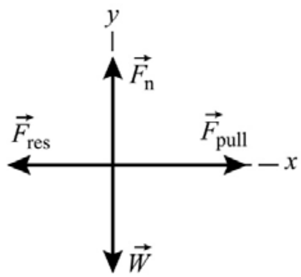
$$a = \frac{F}{m_2 - m_1} = \frac{F}{4m_1 - m_1} = \frac{F}{3m_1} = \tfrac{1}{3} a_1 = \tfrac{1}{3}\left(12\,\mathrm{m/s^2}\right) = \boxed{4.00\,\mathrm{m/s^2}}$$

(*b*) Express and evaluate the acceleration of an object whose mass is $m_2 + m_1$ when the net force acting on it is F:

$$a = \frac{F}{m_2 + m_1} = \frac{F}{4m_1 + m_1} = \frac{F}{5m_1} = \tfrac{1}{5} a_1 = \tfrac{1}{5}\left(12\,\mathrm{m/s^2}\right) = \boxed{2.40\,\mathrm{m/s^2}}$$

36 •

Picture the Problem Because the velocity is constant, the net force acting on the log must be zero. Choose a coordinate system in which the positive x direction is the direction of motion of the log. The free-body diagram shows the forces acting on the log when it is accelerating in the positive x direction.



(*a*) Apply $\sum F_x = ma_x$ to the log when it is moving at constant speed:

$$F_{pull} - F_{res} = ma_x = 0$$

Solve for and evaluate F_{res}:

$$F_{res} = F_{pull} = \boxed{250\,\text{N}}$$

(*b*) Apply $\sum F_x = ma_x$ to the log when it is accelerating to the right:

$$F_{pull} - F_{res} = ma_x$$

Solve for and evaluate F_{pull}:

$$\begin{aligned} F_{pull} &= F_{res} + ma_x \\ &= 250\text{ N} + (75\text{ kg})\,(2\text{ m/s}^2) \\ &= \boxed{400\,\text{N}} \end{aligned}$$

37 •

Picture the Problem The acceleration can be found from Newton's 2nd law. Because both forces are constant, the net force and the acceleration are constant; hence, we can use the constant-acceleration equations to answer questions concerning the motion of the object at various times.

(*a*) Apply Newton's 2nd law to the object to obtain:

$$\begin{aligned} \vec{a} &= \frac{\vec{F}_{net}}{m} = \frac{\vec{F}_1 + \vec{F}_2}{m} \\ &= \frac{(6\,\text{N})\hat{i} + (-14\,\text{N})\hat{j}}{4\,\text{kg}} \\ &= \boxed{(1.50\,\text{m/s}^2)\hat{i} + (-3.50\,\text{m/s}^2)\hat{j}} \end{aligned}$$

(*b*) Using a constant-acceleration equation, express the velocity of the object as a function of time and solve for its velocity when $t = 3$ s:

$$\begin{aligned} \vec{v} &= \vec{v}_0 + \vec{a}t \\ &= 0 + \left[(1.50\,\text{m/s}^2)\hat{i} + (-3.50\,\text{m/s}^2)\hat{j}\right](3\,\text{s}) \\ &= \boxed{(4.50\,\text{m/s})\hat{i} + (-10.5\,\text{m/s})\hat{j}} \end{aligned}$$

(*c*) Express the position of the object in terms of its average velocity and evaluate this expression at $t = 3$ s:

$$\begin{aligned} \vec{r} &= \vec{v}_{av}t \\ &= \tfrac{1}{2}\vec{v}t \\ &= \boxed{(6.75\,\text{m})\hat{i} + (-15.8\,\text{m})\hat{j}} \end{aligned}$$

Mass and Weight

***38 •**

Picture the Problem The mass of the astronaut is independent of gravitational fields and will be the same on the moon or, for that matter, out in deep space.

Express the mass of the astronaut in terms of his weight on earth and the gravitational field at the surface of the earth:

$$m=\frac{w_{\text{earth}}}{g_{\text{earth}}}=\frac{600\ \text{N}}{9.81\ \text{N/kg}}=61.2\ \text{kg}$$

and $\boxed{(c)\ \text{is correct.}}$

39 •

Picture the Problem The weight of an object is related to its mass and the gravitational field through $w = mg$.

(*a*) The weight of the girl is:

$$w=mg=(54\ \text{kg})(9.81\ \text{N/kg})=\boxed{530\ \text{N}}$$

(*b*) Convert newtons to pounds:

$$w=\frac{530\ \text{N}}{4.45\ \text{N/lb}}=\boxed{119\ \text{lb}}$$

40 •

Picture the Problem The mass of an object is related to its weight and the gravitational field.

Find the weight of the man in newtons:

$$165\ \text{lb}=(165\ \text{lb})(4.45\ \text{N/lb})=734\ \text{N}$$

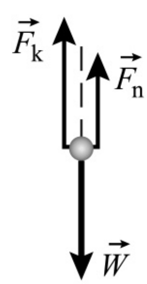
Calculate the mass of the man from his weight and the gravitational field:

$$m=\frac{w}{g}=\frac{734\ \text{N}}{9.81\ \text{N/kg}}=\boxed{74.8\ \text{kg}}$$

Contact Forces

***41 •**

Picture the Problem Draw a free-body diagram showing the forces acting on the block. $\vec{F}_k$ is the force exerted by the spring, $\vec{W}=m\vec{g}$ is the weight of the block, and $\vec{F}_\text{n}$ is the normal force exerted by the horizontal surface. Because the block is resting on a surface, $F_\text{k}+F_\text{n}=W$.



(*a*) Calculate the force exerted by the spring on the block:

$$F_x=kx=(600\ \text{N/m})(0.1\ \text{m})=\boxed{60.0\ \text{N}}$$

(*b*) Choosing the upward direction to be positive, sum the forces acting on the block and solve for F_n:

$$\sum \vec{F} = 0 \Rightarrow F_k + F_n - W = 0$$

and

$$F_n = W - F_k$$

Substitute numerical values and evaluate F_n:

$$F_n = (12\ \text{kg})(9.81\ \text{N/kg}) - 60\ \text{N}$$
$$= \boxed{57.7\ \text{N}}$$

42 •

Picture the Problem Let the positive *x* direction be the direction in which the spring is stretched. We can use Newton's 2nd law and the expression for the force exerted by a stretched (or compressed) spring to express the acceleration of the box in terms of its mass *m*, the stiffness constant of the spring *k*, and the distance the spring is stretched *x*.

Apply Newton's 2nd law to the box to obtain:

$$a = \frac{\sum F}{m}$$

Express the force exerted on the box by the spring:

$$F = -kx$$

Substitute to obtain:

$$a = \frac{-kx}{m}$$

Substitute numerical values and evaluate *a*:

$$a = -\frac{(800\ \text{N/m})(0.04\ \text{m})}{6\ \text{kg}}$$
$$= \boxed{-5.33\ \text{m/s}^2}$$

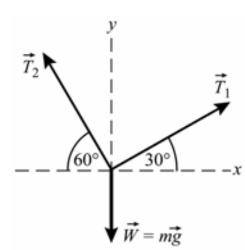
where the minus sign tells us that the box's acceleration is toward its equilibrium position.

Free-Body Diagrams: Static Equilibrium

43 •

Picture the Problem Because the traffic light is not accelerating, the *net* force acting on it must be zero; i.e., $\vec{T}_1 + \vec{T}_2 + m\vec{g} = 0$.

Construct a free-body diagram showing the forces acting on the knot and choose the coordinate system shown:



Apply $\sum F_x = ma_x$ to the knot: $T_1\cos30° - T_2\cos60° = ma_x = 0$

Solve for T_2 in terms of T_1:

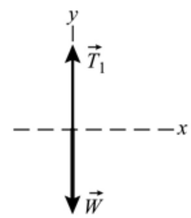
$$T_2 = \frac{\cos 30°}{\cos 60°}T_1 = 1.73T_1$$

$\therefore$ $\boxed{T_2 \text{ is greater than } T_1}$

44 •

Picture the Problem Draw a free-body diagram showing the forces acting on the lamp and apply $\sum F_y = 0$.

From the FBD, it is clear that T_1 supports the full weight mg = 418 N.



Apply $\sum F_y = 0$ to the lamp to obtain: $T_1 - w = 0$

Solve for T_1: $T_1 = w = mg$

Substitute numerical values and evaluate T_1:

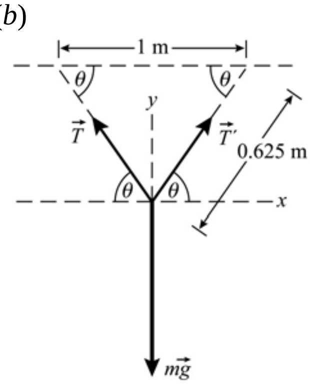
$$T_1 = (42.6\,\text{kg})(9.81\,\text{m/s}^2) = 418\,\text{N}$$

and $\boxed{(b) \text{ is correct.}}$

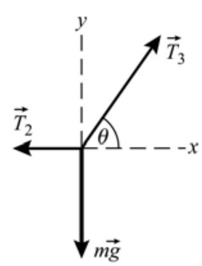
***45** ••

Picture the Problem The free-body diagrams for parts (*a*), (*b*), and (*c*) are shown below. In both cases, the block is in equilibrium under the influence of the forces and we can use Newton's 2nd law of motion and geometry and trigonometry to obtain relationships between θ and the tensions.

(*a*) and (*b*)



(*c*)



(*a*) Referring to the FBD for part (*a*), use trigonometry to determine θ:

$$\theta = \cos^{-1}\frac{0.5\,\text{m}}{0.625\,\text{m}} = \boxed{36.9°}$$

(*b*) Noting that $T = T'$, apply $\sum F_y = ma_y$ to the 0.500-kg block and solve for the tension T:

$$2T\sin\theta - mg = 0 \text{ since } a = 0$$

and

$$T = \frac{mg}{2\sin\theta}$$

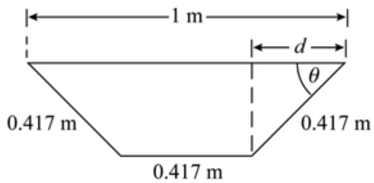
Substitute numerical values and evaluate T:

$$T = \frac{(0.5\,\text{kg})(9.81\,\text{m/s}^2)}{2\sin 36.9°} = \boxed{4.08\,\text{N}}$$

(*c*) The length of each segment is:

$$\frac{1.25\,\text{m}}{3} = 0.417\,\text{m}$$

Find the distance d:



$$d = \frac{1\,\text{m} - 0.417\,\text{m}}{2} = 0.2915\,\text{m}$$

Express θ in terms of d and solve for its value:

$$\theta = \cos^{-1}\left(\frac{d}{0.417\,\text{m}}\right) = \cos^{-1}\left(\frac{0.2915\,\text{m}}{0.417\,\text{m}}\right) = 45.7°$$

Apply $\sum F_y = ma_y$ to the 0.250-kg block and solve for the tension T_3:

$$T_3\sin\theta - mg = 0 \text{ since } a = 0.$$

and

$$T_3 = \frac{mg}{\sin\theta}$$

Substitute numerical values and evaluate T_3:

$$T_3 = \frac{(0.25\,\text{kg})(9.81\,\text{m/s}^2)}{\sin 45.7°} = \boxed{3.43\,\text{N}}$$

Apply $\sum F_x = ma_x$ to the 0.250-kg block and solve for the tension T_2:

$$T_3\cos\theta - T_2 = 0 \text{ since } a = 0.$$

and

$$T_2 = T_3\cos\theta$$

Substitute numerical values and evaluate T_2:

$$T_2 = (3.43\,\text{N})\cos 45.7° = \boxed{2.40\,\text{N}}$$

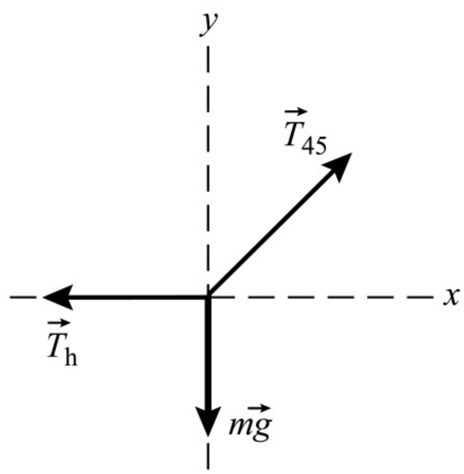
By symmetry:

$$T_1 = T_3 = \boxed{3.43\,\text{N}}$$

46 •

Picture the Problem The suspended body is in equilibrium under the influence of the forces $\vec{T}_h$, $\vec{T}_{45}$, and $m\vec{g}$; i.e., $\vec{T}_h + \vec{T}_{45} + m\vec{g} = 0$

Draw the free-body diagram of the forces acting on the knot just above the 100-N body. Choose a coordinate system with the positive x direction to the right and the positive y direction upward. Apply the conditions for translational equilibrium to determine the tension in the horizontal cord.



If the system is to remain in static equilibrium, the vertical component of T_{45} must be exactly balanced by, and therefore equal to, the tension in the string suspending the 100-N body:

$$T_v = T_{45}\sin 45° = mg$$

Express the horizontal component of T_{45}:

$$T_h = T_{45}\cos 45°$$

Because $T_{45}\sin 45° = T_{45}\cos 45°$:

$$T_h = mg = \boxed{100\ \text{N}}$$

47 •

Picture the Problem The acceleration of *any* object is directly proportional to the *net* force acting on it. Choose a coordinate system in which the positive x direction is the same as that of $\vec{F}_1$ and the positive y direction is to the right. Add the two forces to determine the net force and then use Newton's 2nd law to find the acceleration of the object. If $\vec{F}_3$ brings the system into equilibrium, it must be true that $\vec{F}_3 + \vec{F}_1 + \vec{F}_2 = 0$.

(*a*) Find the components of $\vec{F}_1$ and $\vec{F}_2$:

$$\vec{F}_1 = (20\ \text{N})\hat{\boldsymbol{i}}$$

$$\vec{F}_2 = \{(-30\ \text{N})\sin 30°\}\hat{\boldsymbol{i}} + \{(30\ \text{N})\cos 30°\}\hat{\boldsymbol{j}} = (-15\ \text{N})\hat{\boldsymbol{i}} + (26\ \text{N})\hat{\boldsymbol{j}}$$

Add $\vec{F}_1$ and $\vec{F}_2$ to find $\vec{F}_{tot}$:

$$\vec{F}_{tot} = (5\ \text{N})\hat{\boldsymbol{i}} + (26\ \text{N})\hat{\boldsymbol{j}}$$

Apply $\sum \vec{F} = m\vec{a}$ to find the acceleration of the object:

$$\vec{a} = \frac{\vec{F}_{tot}}{m}$$
$$= \boxed{(0.500\,\text{m/s}^2)\hat{i} + (2.60\,\text{m/s}^2)\hat{j}}$$

(*b*) Because the object is in equilibrium under the influence of the three forces, it must be true that:

$$\vec{F}_3 + \vec{F}_1 + \vec{F}_2 = 0$$
and
$$\vec{F}_3 = -\left(\vec{F}_1 + \vec{F}_2\right)$$
$$= \boxed{(-5.00\,\text{N})\hat{i} + (-26.0\,\text{N})\hat{j}}$$

***48** •

Picture the Problem The acceleration of the object equals the net force, $\vec{T} - m\vec{g}$, divided by the mass. Choose a coordinate system in which upward is the positive y direction. Apply Newton's 2nd law to the forces acting on this body to find the acceleration of the object as a function of T.

(*a*) Apply $\sum F_y = ma_y$ to the object:

$$T - w = T - mg = ma_y$$

Solve this equation for a as a function of T:

$$a_y = \frac{T}{m} - g$$

Substitute numerical values and evaluate a_y:

$$a_y = \frac{5\,\text{N}}{5\,\text{kg}} - 9.81\,\text{m/s}^2 = \boxed{-8.81\,\text{m/s}^2}$$

(*b*) Proceed as in (*a*) with T = 10 N:

$$a = \boxed{-7.81\,\text{m/s}^2}$$

(*c*) Proceed as in (*a*) with T = 100 N:

$$a = \boxed{10.2\,\text{m/s}^2}$$

49 ••

Picture the Problem The picture is in equilibrium under the influence of the three forces shown in the figure. Due to the symmetry of the support system, the vectors $\vec{T}$ and $\vec{T}'$ have the same magnitude T. Choose a coordinate system in which the positive x direction is to the right and the positive y direction is upward. Apply the condition for translational equilibrium to obtain an expression for T as a function of θ and w.

(*a*) Referring to Figure 4-37, apply the condition for translational equilibrium in the vertical direction and solve for T:

$$\sum F_y = 2T\sin\theta - w = 0$$
and
$$T = \boxed{\frac{w}{2\sin\theta}}$$

$T_{\min}$ occurs when $\sin\theta$ is a maximum:

$$\theta = \sin^{-1} 1 = \boxed{90°}$$

$T_{\max}$ occurs when $\sin\theta$ is a minimum. Because the function is undefined when $\sin\theta$ = 0, we can conclude that:

$$\boxed{T \to T_{\max} \text{ as } \theta \to 0°}$$

(*b*) Substitute numerical values in the result in (*a*) and evaluate *T*:

$$T = \frac{(2\,\text{kg})(9.81\,\text{m/s}^2)}{2\sin 30°} = \boxed{19.6\,\text{N}}$$

Remarks: θ = 90° requires wires of infinite length; therefore it is not possible. As θ gets small, *T* gets large without limit.

***50** •••

Picture the Problem In part (*a*) we can apply Newton's 2nd law to obtain the given expression for *F*. In (*b*) we can use a symmetry argument to find an expression for tan θ_0. In (*c*) we can use our results obtained in (*a*) and (*b*) to express x_i and y_i.

(*a*) Apply $\sum F_y = 0$ to the balloon:

$$F + T_\text{i} \sin\theta_\text{i} - T_{\text{i}-1} \sin\theta_{\text{i}-1} = 0$$

Solve for *F* to obtain:

$$F = \boxed{T_{\text{i}-1} \sin\theta_{\text{i}-1} - T_\text{i} \sin\theta_\text{i}}$$

(*b*) By symmetry, each support must balance half of the force acting on the entire arch. Therefore, the vertical component of the force on the support must be *NF*/2. The horizontal component of the tension must be T_H. Express tanθ_0 in terms of *NF*/2 and T_H:

$$\tan\theta_0 = \frac{NF/2}{T_\text{H}} = \frac{NF}{2T_\text{H}}$$

By symmetry, $\theta_{\text{N}+1} = -\theta_0$. Therefore, because the tangent function is odd:

$$\tan\theta_0 = \boxed{-\tan\theta_{\text{N}+1} = \frac{NF}{2T_\text{H}}}$$

(*c*) Using $T_\text{H} = T_\text{i}\cos\theta_\text{i} = T_{\text{i}-1}\cos\theta_{\text{i}-1}$, divide both sides of our result in (*a*) by T_H and simplify to obtain:

$$\frac{F}{T_\text{H}} = \frac{T_{\text{i}-1}\sin\theta_{\text{i}-1}}{T_{\text{i}-1}\cos\theta_{\text{i}-1}} - \frac{T_\text{i}\sin\theta_\text{i}}{T_\text{i}\cos\theta_\text{i}}$$

$$= \tan\theta_{\text{i}-1} - \tan\theta_\text{i}$$

Using this result, express tan θ_1:

$$\tan\theta_1 = \tan\theta_0 - \frac{F}{T_\text{H}}$$

Substitute for tan θ_0 from (*a*):

$$\tan\theta_1 = \frac{NF}{2T_\text{H}} - \frac{F}{T_\text{H}} = (N-2)\frac{F}{2T_\text{H}}$$

Generalize this result to obtain:

$$\boxed{\tan\theta_\mathrm{i} = (N-2i)\frac{F}{2T_\mathrm{H}}}$$

Express the length of rope between two balloons:

$$\ell_{\text{between balloons}} = \frac{L}{N+1}$$

Express the horizontal coordinate of the point on the rope where the ith balloon is attached, x_i, in terms of x_{i-1} and the length of rope between two balloons:

$$x_\mathrm{i} = x_{\mathrm{i}-1} + \frac{L}{N+1}\cos\theta_{\mathrm{i}-1}$$

Sum over all the coordinates to obtain:

$$\boxed{x_\mathrm{i} = \frac{L}{N+1}\sum_{j=0}^{\mathrm{i}-1}\cos\theta_j}$$

Proceed similarly for the vertical coordinates to obtain:

$$\boxed{y_\mathrm{i} = \frac{L}{N+1}\sum_{j=0}^{\mathrm{i}-1}\sin\theta_j}$$

(*d*) A spreadsheet program is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Content/Formula	Algebraic Form
C9	($B$2-2*B9)/(2*$B$4)	$(N-2\mathrm{i})\frac{F}{2T_\mathrm{H}}$

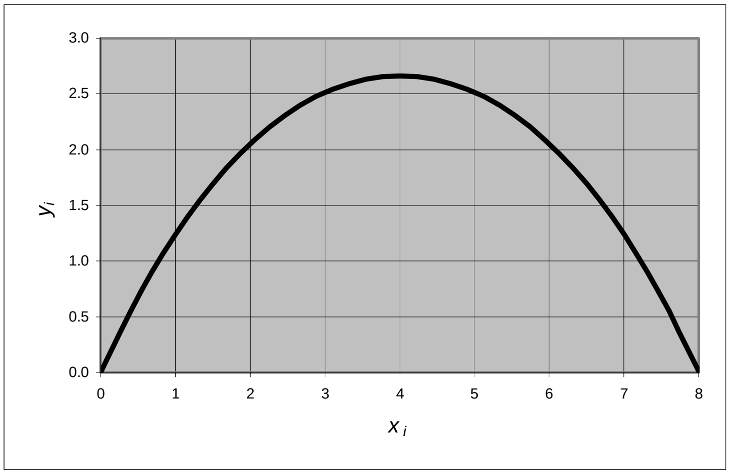
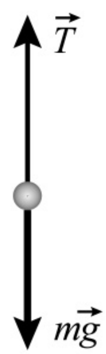
(*e*) A horizontal component of tension 3.72 N gives a spacing of 8 m. At this spacing, the arch is 2.63 m high, tall enough for someone to walk through.



51 ••

Picture the Problem We know, because the speed of the load is changing in parts (*a*) and (*c*), that it is accelerating. We also know that, if the load is accelerating in a particular direction, there must be a *net* force in that direction. A free-body diagram for part (*a*) is shown to the right. We can apply Newton's 2nd law of motion to each part of the problem to relate the tension in the cable to the acceleration of the load. Choose the upward direction to be the positive *y* direction.



(*a*) Apply $\sum F_y = ma_y$ to the load and solve for *T*:

$T - mg = ma$

and

$$T = ma_y + mg = m(a_y + g) \qquad (1)$$

Substitute numerical values and evaluate *T*:

$$T = (1000\,\text{kg})(2\,\text{m/s}^2 + 9.81\,\text{m/s}^2) = \boxed{11.8\,\text{kN}}$$

(*b*) Because the crane is lifting the

$$T = mg = \boxed{9.81\,\text{kN}}$$

load at constant speed, $a = 0$:

(*c*) Because the acceleration of the load is downward, a is negative. Apply $\sum F_y = ma_y$ to the load:

$$T - mg = ma_y$$

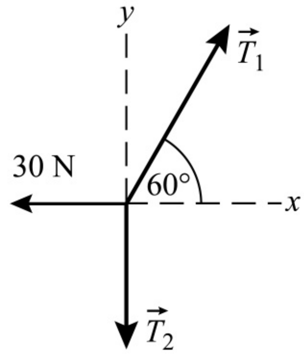
Substitute numerical values in equation (1) and evaluate T:

$$T = (1000\text{ kg})(9.81\text{ m/s}^2 - 2\text{ m/s}^2) = \boxed{7.81\text{ kN}}$$

52 ••

Picture the Problem Draw a free-body diagram for each of the depicted situations and use the conditions for translational equilibrium to find the unknown tensions.

(*a*)



$$\Sigma F_x = T_1\cos 60° - 30\text{ N} = 0$$

and

$$T_1 = (30\text{ N})/\cos 60° = \boxed{60.0\text{ N}}$$

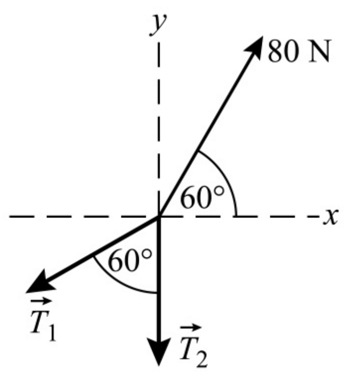
$$\Sigma F_y = T_1\sin 60° - T_2 = 0$$

and

$$T_2 = T_1\sin 60° = \boxed{52.0\text{ N}}$$

$$\therefore\ m = T_2/g = \boxed{5.30\text{ kg}}$$

(*b*)



$$\Sigma F_x = (80\text{ N})\cos 60° - T_1\sin 60° = 0$$

and

$$T_1 = (80\text{ N})\cos 60°/\sin 60° = \boxed{46.2\text{ N}}$$

$$\Sigma F_y = (80\text{ N})\sin 60° - T_2 - T_1\cos 60° = 0$$

$$T_2 = (80\text{ N})\sin 60° - (46.2\text{ N})\cos 60° = \boxed{46.2\text{ N}}$$

$$m = T_2/g = \boxed{4.71\text{ kg}}$$

(*c*)

$$\Sigma F_x = -T_1\cos 60° + T_3\cos 60° = 0$$

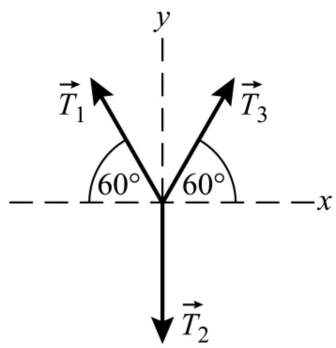
and

$$T_1 = T_3$$

$$\Sigma F_y = 2T_1\sin 60° - mg = 0$$

and

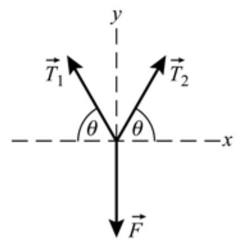
$$T_1 = T_3 = (58.9\text{ N})/(2\sin 60°) = \boxed{34.0\text{ N}}$$



$\therefore\ m = T_1/g = \boxed{3.46\ \text{kg}}$

53 ••

Picture the Problem Construct the free-body diagram for that point in the rope at which you exert the force $\vec{F}$ and choose the coordinate system shown on the FBD. We can apply Newton's 2nd law to the rope to relate the tension to F.



(*a*) Noting that $T_1 = T_2 = T$, apply $\sum F_y = ma_y$ to the car:

$2T\sin\theta - F = ma_y = 0$ because the car's acceleration is zero.

Solve for and evaluate T:

$$T = \frac{F}{2\sin\theta} = \frac{400\ \text{N}}{2\sin 3°} = \boxed{3.82\ \text{kN}}$$

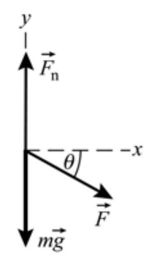
(*b*) Proceed as in part (*a*):

$$T = \frac{600\ \text{N}}{2\sin 4°} = \boxed{4.30\ \text{kN}}$$

Free-Body Diagrams: Inclined Planes and the Normal Force

***54** •

Picture the Problem The free-body diagram shows the forces acting on the box as the man pushes it across the frictionless floor. We can apply Newton's 2nd law of motion to the box to find its acceleration.



Apply $\sum F_x = ma_x$ to the box:

$$F\cos\theta = ma_x$$

Solve for a_x:

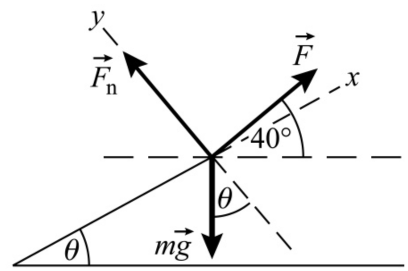
$$a_x = \frac{F\cos\theta}{m}$$

Substitute numerical values and evaluate a_x:

$$a_x = \frac{(250\ \text{N})\cos 35°}{20\ \text{kg}} = \boxed{10.2\ \text{m/s}^2}$$

55 •

Picture the Problem The free-body diagram shows the forces acting on the box as the man pushes it up the frictionless incline. We can apply Newton's 2nd law of motion to the box to determine the smallest force that will move it up the incline at constant speed.



Apply $\sum F_x = ma_x$ to the box as it moves up the incline with constant speed:

$$F_{min}\cos(40° - \theta) - mg\sin\theta = 0$$

Solve for F_{min}:

$$F_{min} = \frac{mg\sin\theta}{\cos(40° - \theta)}$$

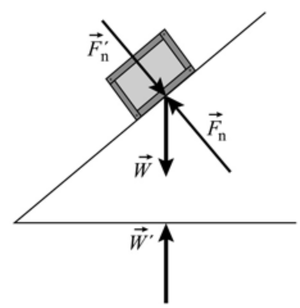
Substitute numerical values and evaluate F_{min}:

$$F_{min} = \frac{(20\,kg)(9.81\,m/s^2)}{\cos 25°} = \boxed{56.0\,N}$$

56 •

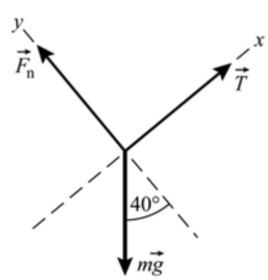
Picture the Problem Forces always occur in equal and opposite pairs. If object *A* exerts a force, $\vec{F}_{B,A}$ on object *B*, an equal but opposite force, $\vec{F}_{A,B} = -\vec{F}_{B,A}$ is exerted by object *B* on object *A*.

The forces acting on the box are its weight, $\vec{W}$, and the normal reaction force of the inclined plane on the box, $\vec{F}_n$. The reaction forces are the forces the box exerts on the inclined plane and the gravitational force the box exerts on the earth. The reaction forces are indicated with primes.



57 •

Picture the Problem Because the block whose mass is *m* is in equilibrium, the sum of the forces $\vec{F}_n$, $\vec{T}$, and $m\vec{g}$ must be zero. Construct the free-body diagram for this object, use the coordinate system shown on the free-body diagram, and apply Newton's 2nd law of motion.



Apply $\sum F_x = ma_x$ to the block on the incline:

$T - mg\sin 40° = ma_x = 0$ because the system is in equilibrium.

Solve for m:

$$m = \frac{T}{g \sin 40°}$$

The tension must equal the weight of the 3.5-kg block because that block is also in equilibrium:

$T = (3.5 \text{ kg})g$

and

$$m = \frac{(3.5\,\text{kg})g}{g \sin 40°} = \frac{3.5\,\text{kg}}{\sin 40°}$$

Because this expression is not included in the list of solution candidates,

$\boxed{(d) \text{ is correct.}}$

Remarks: Because the object whose mass is *m* does not hang vertically, its mass must be greater than 3.5 kg.

***58** •

Picture the Problem The balance(s) indicate the tension in the string(s). Draw free-body diagrams for each of these systems and apply the condition(s) for equilibrium.

(*a*)

$$\sum F_y = T - mg = 0$$

and

$$T = mg = (10\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{98.1\,\text{N}}$$

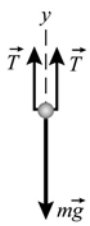
(*b*)

$$\sum F_x = T - T' = 0$$

or, because $T' = mg$,

$$T = T' = mg$$
$$= (10\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{98.1\,\text{N}}$$

(*c*)



$$\sum F_y = 2T - mg = 0$$

and

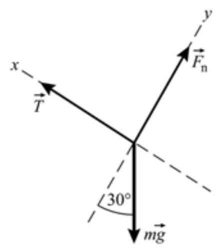
$$T = \tfrac{1}{2} mg$$
$$= \tfrac{1}{2}(10\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{49.1\,\text{N}}$$

(*d*)

$$\sum F_x = T - mg \sin 30° = 0$$

and

$$T = mg \sin 30°$$
$$= (10\,\text{kg})(9.81\,\text{m/s}^2)\sin 30° = \boxed{49.1\,\text{N}}$$



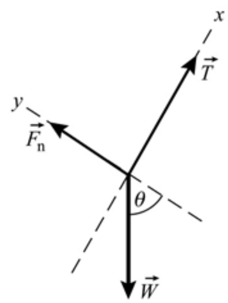
Remarks: Note that (*a*) and (*b*) give the same answers … a rather surprising result until one has learned to draw FBDs and apply the conditions for translational equilibrium.

59 ••

Picture the Problem Because the box is held in place (is in equilibrium) by the forces acting on it, we know that

$$\vec{T} + \vec{F}_n + \vec{W} = 0$$

Choose a coordinate system in which the positive *x* direction is in the direction of $\vec{T}$ and the positive *y* direction is in the direction of $\vec{F}_n$. Apply Newton's 2nd law to the block to obtain expressions for $\vec{T}$ and $\vec{F}_n$.



(*a*) Apply $\sum F_x = ma_x$ to the box: $T - mg\sin\theta = 0$

Solve for *T*: $T = mg\sin\theta$

Substitute numerical values and evaluate *T*: $T = (50\,\text{kg})(9.81\,\text{m/s}^2)\sin 60° = \boxed{425\,\text{N}}$

Apply $\sum F_y = ma_y$ to the box: $F_n - mg\cos\theta = 0$

Solve for F_n: $F_n = mg\cos\theta$

Substitute numerical values and evaluate F_n: $F_n = (50\,\text{kg})(9.81\,\text{m/s}^2)\cos 60° = \boxed{245\,\text{N}}$

(*b*) Using the result for the tension from part (*a*) to obtain:

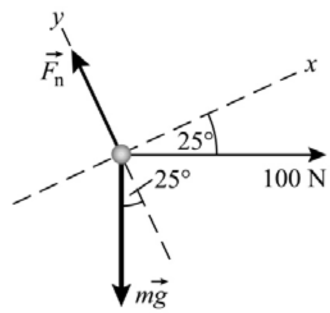
$T_{90°} = mg\sin 90° = \boxed{mg}$

and

$T_{0°} = mg\sin 0° = \boxed{0}$

60 ••

Picture the Problem Draw a free-body diagram for the box. Choose a coordinate system in which the positive x-axis is parallel to the inclined plane and the positive y-axis is in the direction of the normal force the incline exerts on the block. Apply Newton's 2nd law of motion to both the x and y directions.



(a) Apply $\sum F_y = ma_y$ to the block:

$$F_n - mg\cos 25° - (100\,\text{N})\sin 25° = 0$$

Solve for F_n:

$$F_n = mg\cos 25° + (100\,\text{N})\sin 25°$$

Substitute numerical values and evaluate F_n:

$$F_n = (12\,\text{kg})(9.81\,\text{m/s}^2)\cos 25° + (100\,\text{N})\sin 25° = \boxed{149\,\text{N}}$$

(b) Apply $\sum F_x = ma_x$ to the block:

$$(100\,\text{N})\cos 25° - mg\sin 25° = ma$$

Solve for a:

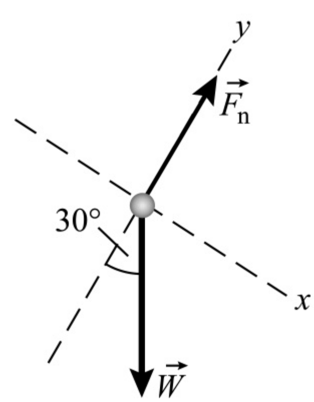
$$a = \frac{(100\,\text{N})\cos 25°}{m} - g\sin 25°$$

Substitute numerical values and evaluate a:

$$a = \frac{(100\,\text{N})\cos 25°}{12\,\text{kg}} - (9.81\,\text{m/s}^2)\sin 25° = \boxed{3.41\,\text{m/s}^2}$$

***61** ••

Picture the Problem The scale reading (the boy's apparent weight) is the force the scale exerts on the boy. Draw a free-body diagram for the boy, choosing a coordinate system in which the positive x-axis is parallel to and down the inclined plane and the positive y-axis is in the direction of the normal force the incline exerts on the boy. Apply Newton's 2nd law of motion in the y direction.



Apply $\sum F_y = ma_y$ to the boy to find F_n. Remember that there is no acceleration in the y direction:

$$F_n - W\cos 30° = 0$$

Substitute for W to obtain:

$$F_n - mg\cos 30° = 0$$

Solve for F_n:

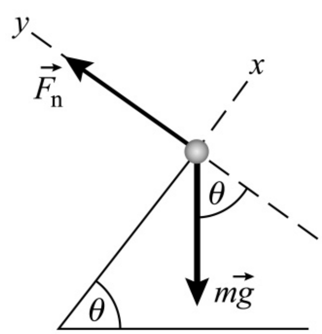
$$F_n = mg\cos 30°$$

Substitute numerical values and evaluate F_n:

$$F_n = (65\,\text{kg})(9.81\,\text{m/s}^2)\cos 30° = \boxed{552\,\text{N}}$$

62 ••

Picture the Problem The free-body diagram for the block sliding up the incline is shown to the right. Applying Newton's 2nd law to the forces acting in the x direction will lead us to an expression for a_x. Using this expression in a constant-acceleration equation will allow us to express h as a function of v_0 and g.



The height h is related to the distance Δx traveled up the incline:

$$h = \Delta x \sin\theta$$

Using a constant-acceleration equation, relate the final speed of the block to its initial speed, acceleration, and distance traveled:

$$v^2 = v_0^2 + 2a_x\Delta x$$

or, because $v = 0$,

$$0 = v_0^2 + 2a_x\Delta x$$

Solve for Δx to obtain:

$$\Delta x = \frac{-v_0^2}{2a_x}$$

Apply $\sum F_x = ma_x$ to the block and solve for its acceleration:

$$-mg\sin\theta = ma_x$$

and

$$a_x = -g\sin\theta$$

Substitute these results in the equation for h and simplify:

$$h = \Delta x\sin\theta = \left(\frac{v_0^2}{2g\sin\theta}\right)\sin\theta = \boxed{\frac{v_0^2}{2g}}$$

which is independent of the ramp's angle θ.

Free-Body Diagrams: Elevators

63 •

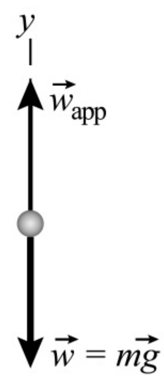
Picture the Problem Because the elevator is descending at constant speed, the object is in equilibrium and $\vec{T} + m\vec{g} = 0$. Draw a free-body diagram of the object and let the upward direction be the positive y direction. Apply Newton's 2nd law with $a = 0$.

Because the downward speed is constant, the acceleration is zero. Apply $\sum F_y = ma_y$ and solve for T:

$T - mg = 0 \Rightarrow T = mg$
and
$\boxed{(a)\text{ is correct.}}$

64 •

Picture the Problem The sketch to the right shows a person standing on a scale in a descending elevator. To its right is a free-body diagram showing the forces acting on the person. The force exerted by the scale on the person, $\vec{w}_{app}$, is the person's apparent weight. Because the elevator is slowing down while descending, the acceleration is directed upward.



Apply $\sum F_y = ma_y$ to the person:

$w_{app} - mg = ma_y$

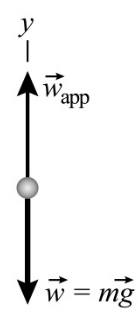
Solve for w_{app}:

$w_{app} = mg + ma_y > mg$

The apparent weight will be higher. Because an upward acceleration is required to "slow" a downward velocity, the normal force exerted on you by the scale (your *apparent weight*) must be greater than your weight.

***65** •

Picture the Problem The sketch to the right shows a person standing on a scale in the elevator immediately after the cable breaks. To its right is the free-body diagram showing the forces acting on the person. The force exerted by the scale on the person, $\vec{w}_{app}$, is the person's apparent weight.



From the free-body diagram we can see that $\vec{w}_{\text{app}} + m\vec{g} = m\vec{a}$ where $\vec{g}$ is the local gravitational field and $\vec{a}$ is the acceleration of the reference frame (elevator). When the elevator goes into free fall ($\vec{a} = \vec{g}$), our equation becomes $\vec{w}_{\text{app}} + m\vec{g} = m\vec{a} = m\vec{g}$. This tells us that $\vec{w}_{\text{app}} = 0$. $\boxed{(e)\text{ is correct.}}$

66 •

Picture the Problem The free-body diagram shows the forces acting on the 10-kg block as the elevator accelerates upward. Apply Newton's 2nd law of motion to the block to find the minimum acceleration of the elevator required to break the cord.

Apply $\sum F_y = ma_y$ to the block: $T - mg = ma_y$

Solve for a_y to determine the minimum breaking acceleration:

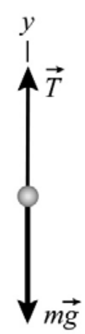
$$a_y = \frac{T - mg}{m} = \frac{T}{m} - g$$

Substitute numerical values and evaluate a_y:

$$a_y = \frac{150\,\text{N}}{10\,\text{kg}} - 9.81\,\text{m/s}^2 = \boxed{5.19\,\text{m/s}^2}$$

67 ••

Picture the Problem The free-body diagram shows the forces acting on the 2-kg block as the elevator ascends at a constant velocity. Because the acceleration of the elevator is zero, the block is in equilibrium under the influence of $\vec{T}$ and $m\vec{g}$. Apply Newton's 2nd law of motion to the block to determine the scale reading.



(*a*) Apply $\sum F_y = ma_y$ to the block to obtain:

$$T - mg = ma_y \quad (1)$$

For motion with constant velocity, $a_y = 0$:

$$T - mg = 0 \text{ and } T = mg$$

Substitute numerical values and evaluate T:

$$T = (2\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{19.6\,\text{N}}$$

(*b*) As in part (*a*), for constant velocity, $a = 0$:

$$T - mg = ma_y$$

and

$$T = (2\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{19.6\,\text{N}}$$

(*c*) Solve equation (1) for *T* and simplify to obtain:

$$T = mg + ma_y = m(g + a_y) \qquad (2)$$

Because the elevator is ascending and its speed is increasing, we have $a_y = 3\ \text{m/s}^2$. Substitute numerical values and evaluate *T*:

$$T = (2\,\text{kg})(9.81\,\text{m/s}^2 + 3\,\text{m/s}^2) = \boxed{25.6\,\text{N}}$$

(*d*) For $0 < t < 5$ s: $a_y = 0$ and

$$T_{0\to 5\,\text{s}} = \boxed{19.6\ \text{N}}$$

Using its definition, calculate *a* for 5 s < t < 9 s:

$$a = \frac{\Delta v}{\Delta t} = \frac{0 - 10\,\text{m/s}}{4\,\text{s}} = -2.5\,\text{m/s}^2$$

Substitute in equation (2) and evaluate *T*:

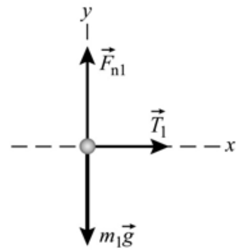
$$T_{5\,\text{s}\to 9\,\text{s}} = (2\,\text{kg})(9.81\,\text{m/s}^2 - 2.5\,\text{m/s}^2) = \boxed{14.6\,\text{N}}$$

Free-Body Diagrams: Ropes, Tension, and Newton's Third Law

68 •

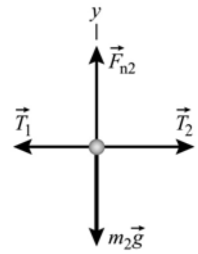
Picture the Problem Draw a free-body diagram for each object and apply Newton's 2nd law of motion. Solve the resulting simultaneous equations for the ratio of T_1 to T_2.

Draw the FBD for the box to the left and apply $\sum F_x = ma_x$:



$$T_1 = m_1 a_1$$

Draw the FBD for the box to the right and apply $\sum F_x = ma_x$:



$$T_2 - T_1 = m_2 a_2$$

The two boxes have the same acceleration:

$$a_1 = a_2$$

Divide the second equation by the first:

$$\frac{T_1}{T_2 - T_1} = \frac{m_1}{m_2}$$

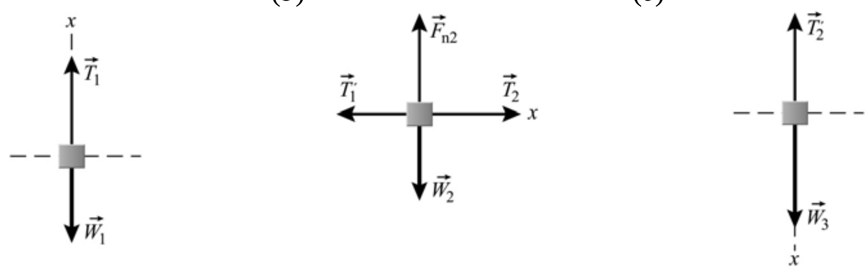
Solve for the ratio T_1/T_2 :

$$\frac{T_1}{T_2} = \frac{m_1}{m_1 + m_2} \text{ and } \boxed{(d) \text{ is correct.}}$$

69 ••

Picture the Problem Call the common acceleration of the boxes a. Assume that box 1 moves upward, box 2 to the right, and box 3 downward and take this direction to be the positive x direction. Draw free-body diagrams for each of the boxes, apply Newton's 2nd law of motion, and solve the resulting equations simultaneously.

(*a*) (*b*) (*c*)



(*a*) Apply $\sum F_x = ma_x$ to the box whose mass is m_1:

$$T_1 - w_1 = m_1 a$$

Apply $\sum F_x = ma_x$ to the box whose mass is m_2:

$$T_2 - T_1 = m_2 a$$

Noting that $T_2 = T_2'$, apply $\sum F_x = ma_x$ to the box whose mass is m_3:

$$w_3 - T_2 = m_3 a$$

Add the three equations to obtain:

$$w_3 - w_1 = (m_1 + m_2 + m_3)a$$

Solve for a:

$$a = \frac{(m_3 - m_1)g}{m_1 + m_2 + m_3}$$

Substitute numerical values and evaluate a:

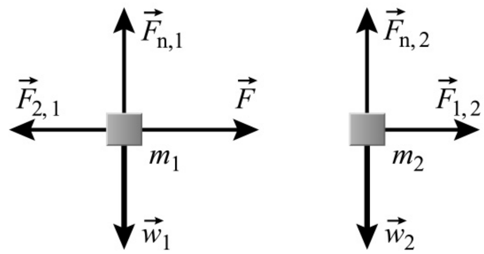
$$a = \frac{(2.5\,\text{kg} - 1.5\,\text{kg})(9.81\,\text{m/s}^2)}{1.5\,\text{kg} + 3.5\,\text{kg} + 2.5\,\text{kg}} = \boxed{1.31\,\text{m/s}^2}$$

(*b*) Substitute for the acceleration in the equations obtained above to find the tensions:

$$T_1 = \boxed{16.7\,\text{N}} \text{ and } T_2 = \boxed{21.3\,\text{N}}$$

***70** ••

Picture the Problem Choose a coordinate system in which the positive x direction is to the right and the positive y direction is upward. Let $\vec{F}_{2,1}$ be the contact force exerted by m_2 on m_1 and $\vec{F}_{1,2}$ be the force exerted by m_1 on m_2. These forces are equal and opposite so $\vec{F}_{2,1} = -\vec{F}_{1,2}$. The free-body diagrams for the blocks are shown to the right. Apply Newton's 2nd law to each block separately and use the fact that their accelerations are equal.



(*a*) Apply $\sum F_x = ma_x$ to the first block:

$$F - F_{2,1} = m_1 a_1 = m_1 a$$

Apply $\sum F_x = ma_x$ to the second block:

$$F_{1,2} = m_2 a_2 = m_2 a \quad (1)$$

Add these equations to eliminate $F_{2,1}$ and $F_{1,2}$ and solve for $a = a_1 = a_2$:

$$a = \boxed{\frac{F}{m_1 + m_2}}$$

Substitute your value for a into equation (1) and solve for $F_{1,2}$:

$$F_{1,2} = \boxed{\frac{Fm_2}{m_1 + m_2}}$$

(*b*) Substitute numerical values in the equations derived in part (*a*) and evaluate a and $F_{1,2}$:

$$a = \frac{3.2\,\text{N}}{2\,\text{kg} + 6\,\text{kg}} = \boxed{0.400\,\text{m/s}^2}$$

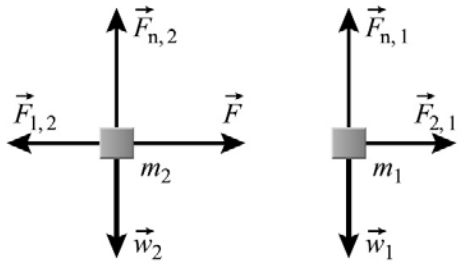
and

$$F_{1,2} = \frac{(3.2\,\text{N})(6\,\text{kg})}{2\,\text{kg} + 6\,\text{kg}} = \boxed{2.40\,\text{N}}$$

Remarks: Note that our results for the acceleration are the same as if the force *F* had acted on a single object whose mass is equal to the sum of the masses of the two blocks. In fact, because the two blocks have the same acceleration, we can consider them to be a single system with mass $m_1 + m_2$.

71 •

Picture the Problem Choose a coordinate system in which the positive x direction is to the right and the positive y direction is upward. Let $\vec{F}_{2,1}$ be the contact force exerted by m_2 on m_1 and $\vec{F}_{1,2}$ be the force exerted by m_1 on m_2. These forces are equal and opposite so $\vec{F}_{2,1} = -\vec{F}_{1,2}$. The free-body diagrams for the blocks are shown. We can apply Newton's 2nd law to each block separately and use the fact that their accelerations are equal.



(*a*) Apply $\sum F_x = ma_x$ to the first block:

$$F - F_{1,2} = m_2 a_2 = m_2 a$$

Apply $\sum F_x = ma_x$ to the second block:

$$F_{2,1} = m_1 a_1 = m_1 a \qquad (1)$$

Add these equations to eliminate $F_{2,1}$ and $F_{1,2}$ and solve for $a = a_1 = a_2$:

$$a = \boxed{\frac{F}{m_1 + m_2}}$$

Substitute your value for a into equation (1) and solve for $F_{2,1}$:

$$F_{2,1} = \boxed{\frac{Fm_1}{m_1 + m_2}}$$

(*b*) Substitute numerical values in the equations derived in part (*a*) and evaluate a and $F_{2,1}$:

$$a = \frac{3.2\,\text{N}}{2\,\text{kg} + 6\,\text{kg}} = \boxed{0.400\,\text{m/s}^2}$$

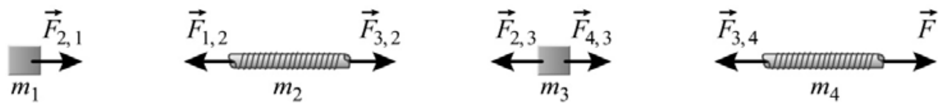
and

$$F_{2,1} = \frac{(3.2\,\text{N})(2\,\text{kg})}{2\,\text{kg} + 6\,\text{kg}} = \boxed{0.800\,\text{N}}$$

Remarks: Note that our results for the acceleration are the same as if the force *F* had acted on a single object whose mass is equal to the sum of the masses of the two blocks. In fact, because the two blocks have the same acceleration, we can consider them to be a single system with mass $m_1 + m_2$.

72 ••

Picture the Problem The free-body diagrams for the boxes and the ropes are below. Because the vertical forces have no bearing on the problem they have not been included. Let the numeral 1 denote the 100-kg box to the left, the numeral 2 the rope connecting the boxes, the numeral 3 the box to the right and the numeral 4 the rope to which the force $\vec{F}$ is applied. $\vec{F}_{3,4}$ is the tension force exerted by m_3 on m_4, $\vec{F}_{4,3}$ is the tension force exerted by m_4 on m_3, $\vec{F}_{2,3}$ is the tension force exerted by m_2 on m_3, $\vec{F}_{3,2}$ is the tension force exerted by m_3 on m_2, $\vec{\boldsymbol{F}}_{1,2}$ is the tension force exerted by m_1 on m_2, and $\vec{\boldsymbol{F}}_{2,1}$ is the tension force exerted by m_2 on m_1. The equal and opposite pairs of forces are $\vec{\boldsymbol{F}}_{2,1} = -\vec{\boldsymbol{F}}_{1,2}$, $\vec{\boldsymbol{F}}_{3,2} = -\vec{\boldsymbol{F}}_{2,3}$, and $\vec{\boldsymbol{F}}_{4,3} = -\vec{\boldsymbol{F}}_{3,4}$. We can apply Newton's 2nd law to each box and rope separately and use the fact that their accelerations are equal.



Apply $\sum \vec{\boldsymbol{F}} = m\vec{\boldsymbol{a}}$ to the box whose mass is m_1:

$$F_{2,1} = m_1 a_1 = m_1 a \quad (1)$$

Apply $\sum \vec{\boldsymbol{F}} = m\vec{\boldsymbol{a}}$ to the rope whose mass is m_2:

$$F_{3,2} - F_{1,2} = m_2 a_2 = m_2 a \quad (2)$$

Apply $\sum \vec{\boldsymbol{F}} = m\vec{\boldsymbol{a}}$ to the box whose mass is m_3:

$$F_{4,3} - F_{2,3} = m_3 a_3 = m_3 a \quad (3)$$

Apply $\sum \vec{\boldsymbol{F}} = m\vec{\boldsymbol{a}}$ to the rope whose mass is m_4:

$$F - F_{3,4} = m_4 a_4 = m_4 a$$

Add these equations to eliminate $F_{2,1}$, $F_{1,2}$, $F_{3,2}$, $F_{2,3}$, $F_{4,3}$, and $F_{3,4}$ and solve for F:

$$F = (m_1 + m_2 + m_3 + m_4)a = (202\,\text{kg})(1.0\,\text{m/s}^2) = \boxed{202\,\text{N}}$$

Use equation (1) to find the tension at point A:

$$F_{2,1} = (100\,\text{kg})(1.0\,\text{m/s}^2) = \boxed{100\,\text{N}}$$

Use equation (2) to find the tension at point B:

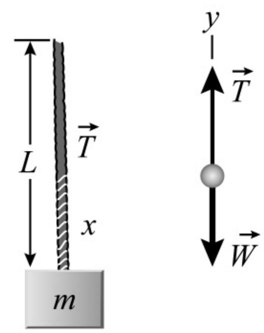
$$F_{3,2} = F_{1,2} + m_2 a = 100\,\text{N} + (1\,\text{kg})(1.0\,\text{m/s}^2) = \boxed{101\,\text{N}}$$

Use equation (3) to find the tension at point C:

$$F_{4,3} = F_{2,3} + m_3 a = 101\,\text{N} + (100\,\text{kg})(1.0\,\text{m/s}^2) = \boxed{201\,\text{N}}$$

73 ••

Picture the Problem Because the distribution of mass in the rope is uniform, we can express the mass m' of a length x of the rope in terms of the total mass of the rope M and its length L. We can then express the total mass that the rope must support at a distance x above the block and use Newton's 2nd law to find the tension as a function of x.



Set up a proportion expressing the mass m' of a length x of the rope as a function of M and L and solve for m':

$$\frac{m'}{x}=\frac{M}{L}\Rightarrow m'=\frac{M}{L}x$$

Express the total mass that the rope must support at a distance x above the block:

$$m+m'=m+\frac{M}{L}x$$

Apply $\sum F_y = ma_y$ to the block and a length x of the rope:

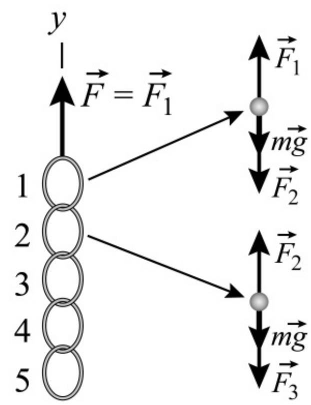
$$T-w=T-\left(m+\frac{M}{L}x\right)g$$
$$=\left(m+\frac{M}{L}x\right)a$$

Solve for T to obtain:

$$T=\boxed{(a+g)\left(m+\frac{M}{L}x\right)}$$

***74** ••

Picture the Problem Choose a coordinate system with the positive y direction upward and denote the top link with the numeral 1, the second with the numeral 2, etc.. The free-body diagrams show the forces acting on links 1 and 2. We can apply Newton's 2nd law to each link to obtain a system of simultaneous equations that we can solve for the force each link exerts on the link below it. Note that the net force on each link is the product of its mass and acceleration.



(*a*) Apply $\sum F_y = ma_y$ to the top link and solve for F:

$$F-5mg=5ma$$

and

$$F=5m(g+a)$$

Substitute numerical values and evaluate F:

$$F = 5(0.1\,\text{kg})(9.81\,\text{m/s}^2 + 2.5\,\text{m/s}^2) = \boxed{6.16\,\text{N}}$$

(*b*) Apply $\sum F_y = ma_y$ to a single link:

$$F_{1\,\text{link}} = m_{1\,\text{link}}a = (0.1\,\text{kg})(2.5\,\text{m/s}^2) = \boxed{0.250\,\text{N}}$$

(*c*) Apply $\sum F_y = ma_y$ to the 1st through 5th links to obtain:

$$F - F_2 - mg = ma\,, \quad (1)$$
$$F_2 - F_3 - mg = ma\,, \quad (2)$$
$$F_3 - F_4 - mg = ma\,, \quad (3)$$
$$F_4 - F_5 - mg = ma\,, \text{ and} \quad (4)$$
$$F_5 - mg = ma \quad (5)$$

Add equations (2) through (5) to obtain:

$$F_2 - 4mg = 4ma$$

Solve for F_2 to obtain:

$$F_2 = 4mg + 4ma = 4m(a + g)$$

Substitute numerical values and evaluate F_2:

$$F_2 = 4(0.1\,\text{kg})(9.81\,\text{m/s}^2 + 2.5\,\text{m/s}^2) = \boxed{4.92\,\text{N}}$$

Substitute for F_2 to find F_3, and then substitute for F_3 to find F_4:

$$F_3 = \boxed{3.69\,\text{N}} \text{ and } F_4 = \boxed{2.46\,\text{N}}$$

Solve equation (5) for F_5:

$$F_5 = m(g + a)$$

Substitute numerical values and evaluate F_5:

$$F_5 = (0.1\,\text{kg})(9.81\,\text{m/s}^2 + 2.5\,\text{m/s}^2) = \boxed{1.23\,\text{N}}$$

75 •

Picture the Problem A *net* force is required to accelerate the object. In this problem the net force is the difference between $\vec{T}$ and $\vec{W}(= m\vec{g})$. The free-body diagram of the object is shown to the right. Choose a coordinate system in which the upward direction is positive.

Apply $\sum \vec{F} = m\vec{a}$ to the object to obtain:

$$F_{\text{net}} = T - W = T - mg$$

Solve for the tension in the lower portion of the rope:

$$T = F_{\text{net}} + mg = ma + mg = m(a + g)$$

Using its definition, find the acceleration of the object:

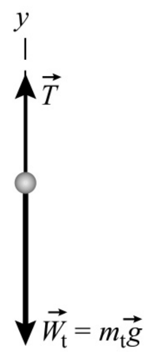
$a \equiv \Delta v/\Delta t = (3.5\text{ m/s})/(0.7\text{ s}) = 5.00\text{ m/s}^2$

Substitute numerical values and evaluate T:

$T = (40\text{ kg})(5.00\text{ m/s}^2 + 9.81\text{ m/s}^2) = 592\text{ N}$ and $\boxed{(a)\text{ is correct.}}$

76 •

Picture the Problem A net force in the downward direction is required to accelerate the truck downward. The net force is the difference between $\vec{W}_\text{t}$ and $\vec{T}$. A free-body diagram showing these forces acting on the truck is shown to the right. Choose a coordinate system in which the downward direction is positive.



Apply $\sum F_y = ma_y$ to the truck to obtain:

$T - m_\text{t}g = m_\text{t}a_y$

Solve for the tension in the lower portion of the cable:

$T = m_\text{t}g + m_\text{t}a_y = m_\text{t}(g + a_y)$

Substitute to find the tension in the rope:

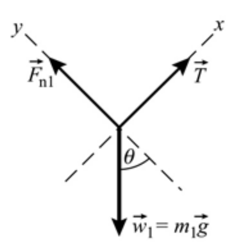
$T = m_\text{t}(g - 0.1g) = 0.9m_\text{t}g$

and $\boxed{(c)\text{ is correct.}}$

77 ••

Picture the Problem Because the string does not stretch or become slack, the two objects must have the same speed and therefore the magnitude of the acceleration is the same for each object. Choose a coordinate system in which up the incline is the positive x direction for the object of mass m_1 and downward is the positive x direction for the object of mass m_2. This idealized pulley acts like a piece of polished pipe; i.e., its only function is to change the direction the tension in the massless string acts. Draw a free-body diagram for each of the two objects, apply Newton's 2nd law of motion to both objects, and solve the resulting equations simultaneously.

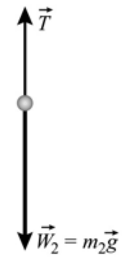
(*a*) Draw the FBD for the object of mass m_1:



Apply $\sum F_x = ma_x$ to the object whose mass is m_1:

$T - m_1g\sin\theta = m_1a$

Draw the FBD for the object of mass m_2:



Apply $\sum F_x = ma_x$ to the object whose mass is m_2:

$$m_2 g - T = m_2 a$$

Add the two equations and solve for a:

$$a = \boxed{\frac{g(m_2 - m_1 \sin\theta)}{m_1 + m_2}}$$

Substitute for a in either of the equations containing the tension and solve for T:

$$T = \boxed{\frac{g m_1 m_2 (1 + \sin\theta)}{m_1 + m_2}}$$

(*b*) Substitute the given values into the expression for a:

$$a = \boxed{2.45\,\text{m/s}^2}$$

Substitute the given data into the expression for T:

$$T = \boxed{36.8\,\text{N}}$$

78 •

Picture the Problem The magnitude of the accelerations of Peter and the counterweight are the same. Choose a coordinate system in which up the incline is the positive x direction for the counterweight and downward is the positive x direction for Peter. The pulley changes the direction the tension in the rope acts. Let Peter's mass be m_P. Ignoring the mass of the rope, draw free-body diagrams for the counterweight and Peter, apply Newton's 2nd law to each of them, and solve the resulting equations simultaneously.

(*a*) Using a constant-acceleration equation, relate Peter's displacement to her acceleration and descent time:

$$\Delta x = v_0 \Delta t + \tfrac{1}{2} a (\Delta t)^2$$

or, because $v_0 = 0$,

$$\Delta x = \tfrac{1}{2} a (\Delta t)^2$$

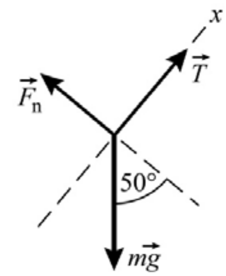
Solve for the common acceleration of Peter and the counterweight:

$$a = \frac{2\Delta x}{(\Delta t)^2}$$

Substitute numerical values and evaluate a:

$$a = \frac{2(3.2\,\text{m})}{(2.2\,\text{s})^2} = 1.32\,\text{m/s}^2$$

Draw the FBD for the counterweight:



Apply $\sum F_x = ma_x$ to the counterweight:

$$T - mg\sin 50° = ma$$

Draw the FBD for Peter:

Apply $\sum F_x = ma_x$ to Peter:

$$m_P g - T = m_P a$$

Add the two equations and solve for m:

$$m = \frac{m_P(g-a)}{a + g\sin 50°}$$

Substitute numerical values and evaluate m:

$$m = \frac{(50\,\text{kg})(9.81\,\text{m/s}^2 - 1.32\,\text{m/s}^2)}{1.32\,\text{m/s}^2 + (9.81\,\text{m/s}^2)\sin 50°} = \boxed{48.0\,\text{kg}}$$

(*b*) Substitute for m in the force equation for the counterweight and solve for T:

$$T = m(a + g\sin 50°)$$

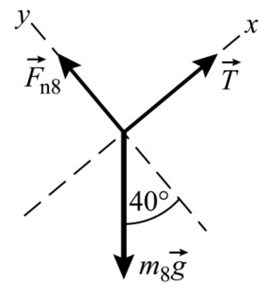
(*b*) Substitute numerical values and evaluate T:

$$T = (48.0\,\text{kg})\left[1.32\,\text{m/s}^2 + (9.81\,\text{m/s}^2)\sin 50°\right] = \boxed{424\,\text{N}}$$

79 ••

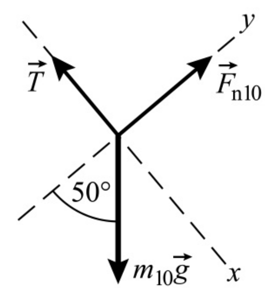
Picture the Problem The magnitude of the accelerations of the two blocks are the same. Choose a coordinate system in which up the incline is the positive *x* direction for the 8-kg object and downward is the positive *x* direction for the 10-kg object. The peg changes the direction the tension in the rope acts. Draw free-body diagrams for each object, apply Newton's 2nd law of motion to both of them, and solve the resulting equations simultaneously.

(*a*) Draw the FBD for the 3-kg object:



Apply $\sum F_x = ma_x$ to the 3-kg block: $T - m_8 g \sin 40° = m_3 a$

Draw the FBD for the 10-kg object:



Apply $\sum F_x = ma_x$ to the 10-kg block: $m_{10} g \sin 50° - T = m_{10} a$

Add the two equations and solve for and evaluate a:

$$a = \frac{g\left(m_{10}\sin 50° - m_8 \sin 40°\right)}{m_8 + m_{10}}$$

$$= \boxed{1.37\,\text{m/s}^2}$$

Substitute for a in the first of the two force equations and solve for T:

$$T = m_8 g \sin 40° + m_8 a$$

Substitute numerical values and evaluate T:

$$T = (8\,\text{kg})\left[\left(9.81\,\text{m/s}^2\right)\sin 40° + 1.37\,\text{m/s}^2\right]$$

$$= \boxed{61.4\,\text{N}}$$

(*b*) Because the system is in equilibrium, set $a = 0$, express the force equations in terms of m_1 and m_2, add the two force equations, and solve for and evaluate the ratio m_1/m_2:

$T - m_1 g \sin 40° = 0$

$m_2 g \sin 50° - T = 0$

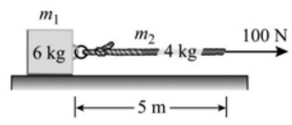
$\therefore\ m_2 g \sin 50° - m_1 g \sin 40° = 0$

and

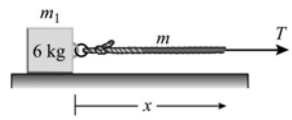
$$\frac{m_1}{m_2} = \frac{\sin 50°}{\sin 40°} = \boxed{1.19}$$

80 ••

Picture the Problem The pictorial representations shown to the right summarize the information given in this problem. While the mass of the rope is distributed over its length, the rope and the 6-kg block have a common acceleration. Choose a coordinate system in which the direction of the 100-N force is the positive *x* direction. Because the surface is horizontal and frictionless, the only force that influences our solution is the 100-N force.



Part (a)



Part (b)

(*a*) Apply $\sum F_x = ma_x$ to the objects shown for part (*a*):

$$100\text{ N} = (m_1 + m_2)a$$

Solve for *a* to obtain:

$$a = \frac{100\text{ N}}{m_1 + m_2}$$

Substitute numerical values and evaluate *a*:

$$a = \frac{100\text{ N}}{10\text{ kg}} = \boxed{10.0\text{ m/s}^2}$$

(*b*) Let *m* represent the mass of a length *x* of the rope. Assuming that the mass of the rope is uniformly distributed along its length:

$$\frac{m}{x} = \frac{m_2}{L_{\text{rope}}} = \frac{4\text{ kg}}{5\text{ m}}$$

and

$$m = \left(\frac{4\text{ kg}}{5\text{ m}}\right)x$$

Let *T* represent the tension in the rope at a distance *x* from the point at which it is attached to the 6-kg block. Apply $\sum F_x = ma_x$ to the system shown for part (*b*) and solve for *T*:

$$T = (m_1 + m)a$$

$$= \left[6\text{ kg} + \left(\frac{4\text{ kg}}{5\text{ m}}\right)x\right]\left(10\text{ m/s}^2\right)$$

$$= \boxed{60\text{ N} + (8\text{ N/m})x}$$

***81** ••

Picture the Problem Choose a coordinate system in which upward is the positive *y* direction and draw the free-body diagram for the frame-plus- painter. Noting that $\vec{F} = -\vec{T}$, apply Newton's 2[nd] law of motion.

(*a*) Letting $m_{\text{tot}} = m_{\text{frame}} + m_{\text{painter}}$,

$$2T - m_{\text{tot}}g = m_{\text{tot}}a$$

and

apply $\sum F_y = ma_y$ to the frame-plus-painter and solve T:

$$T = \frac{m_{tot}(a+g)}{2}$$

Substitute numerical values and evaluate T:

$$T = \frac{(75\,\text{kg})(0.8\,\text{m/s}^2 + 9.81\,\text{m/s}^2)}{2} = 398\,\text{N}$$

Because $F = T$:

$$F = \boxed{398\,\text{N}}$$

(*b*) Apply $\sum F_y = ma_y$ with $a = 0$ to obtain:

$$2T - m_{tot}g = 0$$

Solve for T:

$$T = \tfrac{1}{2}m_{tot}g$$

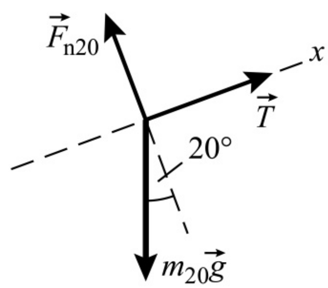
Substitute numerical values and evaluate T:

$$T = \tfrac{1}{2}(75\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{368\,\text{N}}$$

82 •••

Picture the Problem Choose a coordinate system in which up the incline is the positive x direction and draw free-body diagrams for each block. Noting that $\vec{a}_{20} = -\vec{a}_{10}$, apply Newton's 2nd law of motion to each block and solve the resulting equations simultaneously.

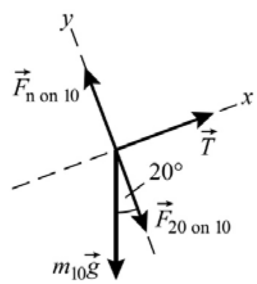
Draw a FBD for the 20-kg block:



Apply $\sum F_x = ma_x$ to the block to obtain:

$$T - m_{20}g\sin 20° = m_{20}a_{20}$$

Draw a FBD for the 10-kg block. Because all the surfaces, including the surfaces between the blocks, are frictionless, the force the 20-kg block exerts on the 10-kg block must be normal to their surfaces as shown to the right.



Apply $\sum F_x = ma_x$ to the block to obtain:

$$T - m_{10}g\sin 20° = m_{10}a_{10}$$

Because the blocks are connected by a taut string: $a_{20} = -a_{10}$

Substitute for a_{20} and eliminate T between the two equations to obtain: $a_{10} = \boxed{1.12\,\text{m/s}^2}$

and

$a_{20} = \boxed{-1.12\,\text{m/s}^2}$

Substitute for either of the accelerations in the force equations and solve for T: $T = \boxed{44.8\,\text{N}}$

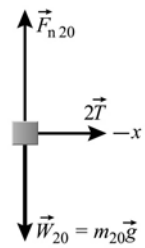
83 •••

Picture the Problem Choose a coordinate system in which the positive x direction is to the right and draw free-body diagrams for each block. Because of the pulley, the string exerts a force of $2T$. Apply Newton's 2nd law of motion to both blocks and solve the resulting equations simultaneously.

(a) Noting the effect of the pulley, express the distance the 20-kg block moves in a time Δt:

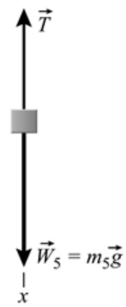
$$\Delta x_{20} = \tfrac{1}{2}\Delta x_5 = \tfrac{1}{2}(10\,\text{cm}) = \boxed{5.00\,\text{cm}}$$

(b) Draw a FBD for the 20-kg block:



Apply $\sum F_x = ma_x$ to the block to obtain: $2T = m_{20}a_{20}$

Draw a FBD for the 5-kg block:



Apply $\sum F_x = ma_x$ to the block to obtain: $m_5g - T = m_5a_5$

Using a constant-acceleration equation, relate the displacement of the 5-kg block to its acceleration

$$\Delta x_5 = \tfrac{1}{2}a_5(\Delta t)^2$$

and the time during which it is accelerated:

Using a constant-acceleration equation, relate the displacement of the 20-kg block to its acceleration and the time during which it is accelerated:

$$\Delta x_{20} = \tfrac{1}{2}a_{20}(\Delta t)^2$$

Divide the first of these equations by the second to obtain:

$$\frac{\Delta x_5}{\Delta x_{20}} = \frac{\tfrac{1}{2}a_5(\Delta t)^2}{\tfrac{1}{2}a_{20}(\Delta t)^2} = \frac{a_5}{a_{20}}$$

Use the result of part (*a*) to obtain:

$$a_5 = 2a_{20}$$

Let $a_{20} = a$. Then $a_5 = 2a$ and the force equations become:

$$2T = m_{20}a$$

and

$$m_5 g - T = m_5(2a)$$

Eliminate T between the two equations to obtain:

$$a = a_{20} = \frac{m_5 g}{2m_5 + \tfrac{1}{2}m_{20}}$$

Substitute numerical values and evaluate a_{20} and a_5:

$$a_{20} = \frac{(5\,\text{kg})(9.81\,\text{m/s}^2)}{2(5\,\text{kg}) + \tfrac{1}{2}(20\,\text{kg})} = \boxed{2.45\,\text{m/s}^2}$$

and

$$a_5 = 2(2.45\,\text{m/s}^2) = \boxed{4.91\,\text{m/s}^2}$$

Substitute for either of the accelerations in either of the force equations and solve for T:

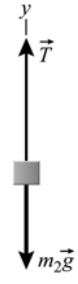
$$T = \boxed{24.5\,\text{N}}$$

Free-Body Diagrams: The Atwood's Machine

***84** ••

Picture the Problem Assume that $m_1 > m_2$. Choose a coordinate system in which the positive y direction is downward for the block whose mass is m_1 and upward for the block whose mass is m_2 and draw free-body diagrams for each block. Apply Newton's 2nd law of motion to both blocks and solve the resulting equations simultaneously.

Draw a FBD for the block whose mass is m_2:



Apply $\sum F_y = ma_y$ to this block:

$T - m_2g = m_2a_2$

Draw a FBD for the block whose mass is m_1:

Apply $\sum F_y = ma_y$ to this block:

$m_1g - T = m_1a_1$

Because the blocks are connected by a taut string, let a represent their common acceleration:

$a = a_1 = a_2$

Add the two force equations to eliminate T and solve for a:

$m_1g - m_2g = m_1a + m_2a$
and

$$\boxed{a = \frac{m_1 - m_2}{m_1 + m_2}g}$$

Substitute for a in either of the force equations and solve for T:

$$\boxed{T = \frac{2m_1m_2g}{m_1 + m_2}}$$

85 ••

Picture the Problem The acceleration can be found from the given displacement during the first second. The ratio of the two masses can then be found from the acceleration using the first of the two equations derived in Problem 89 relating the acceleration of the Atwood’s machine to its masses.

Using a constant-acceleration equation, relate the displacement of the masses to their acceleration and solve for the acceleration:

$\Delta y = v_0t + \frac{1}{2}a(\Delta t)^2$
or, because $v_0 = 0$,
$\Delta y = \frac{1}{2}a(\Delta t)^2$

Solve for and evaluate a:

$$a = \frac{2\Delta y}{(\Delta t)^2} = \frac{2(0.3\,\text{m})}{(1\,\text{s})^2} = 0.600\,\text{m/s}^2$$

Solve for m_1 in terms of m_2 using the first of the two equations given in Problem 84:

$$m_1 = m_2\frac{g + a}{g - a} = \frac{10.41\,\text{m/s}^2}{9.21\,\text{m/s}^2}m_2 = 1.13m_2$$

Find the second mass for m_2 or $m_1 = 1.2$ kg:

$$m_{\text{2nd mass}} = \boxed{1.36\,\text{kg or } 1.06\,\text{kg}}$$

86 ••

Picture the Problem Let F_{nm} be the force the block of mass m_2 exerts on the pebble of mass m. Because $m_2 < m_1$, the block of mass m_2 accelerates upward. Draw a free-body diagram for the pebble and apply Newton's 2nd law and the acceleration equation given in Problem 84.

Apply $\sum F_y = ma_y$ to the pebble: $F_{nm} - mg = ma$

Solve for F_{nm}: $F_{nm} = m(a + g)$

From Problem 84: $$a = \frac{m_1 - m_2}{m_1 + m_2} g$$

Substitute for a and simplify to obtain: $$F_{nm} = m\left(\frac{m_1 - m_2}{m_1 + m_2} g + g\right) = \boxed{\frac{2m_1 m}{m_1 + m_2} g}$$

87 ••

Picture the Problem Note from the free-body diagrams for Problem 89 that the net force exerted by the accelerating blocks is $2T$. Use this information, together with the expression for T given in Problem 84, to derive an expression for $F = 2T$.

From Problem 84 we have: $$T = \frac{2m_1 m_2 g}{m_1 + m_2}$$

The net force, F, exerted by the Atwood's machine on the hanger is: $$F = 2T = \boxed{\frac{4m_1 m_2 g}{m_1 + m_2}}$$

If $m_1 = m_2 = m$, then: $$F = \frac{4m^2 g}{2m} = 2mg$$ … as expected.

If either m_1 or $m_2 = 0$, then: $F = 0$ … also as expected.

88 •••

Picture the Problem Use a constant-acceleration equation to relate the displacement of the descending (or rising) mass as a function of its acceleration and then use one of the results from Problem 84 to relate a to g. Differentiation of our expression for g will allow us to relate uncertainty in the time measurement to uncertainty in the measured value for g … and to the values of m_2 that would yield an experimental value for g that is good to within 5%.

(*a*) Use the result given in Problem 84 to express g in terms of a:

$$g = a\frac{m_1 + m_2}{m_1 - m_2} \qquad (1)$$

Using a constant-acceleration equation, express the displacement, L, as a function of t and solve for the acceleration:

$$\Delta y = L = v_0\Delta t + \tfrac{1}{2}a(\Delta t)^2$$

or, because $v_0 = 0$ and $\Delta t = t$,

$$a = \frac{2L}{t^2} \qquad (2)$$

Substitute this expression for a:

$$g = \boxed{\frac{2L}{t^2}\left(\frac{m_1 + m_2}{m_1 - m_2}\right)}$$

(*b*) Evaluate dg/dt to obtain:

$$\frac{dg}{dt} = -4Lt^{-3}\left(\frac{m_1 + m_2}{m_1 - m_2}\right)$$

$$= \frac{-2}{t}\left[\frac{2L}{t^2}\right]\left(\frac{m_1 + m_2}{m_1 - m_2}\right) = \frac{-2g}{t}$$

Divide both sides of this expression by g and multiply both sides by dt:

$$\boxed{\frac{dg}{g} = -2\frac{dt}{t}}$$

(*c*) We have:

$$\frac{dg}{g} = \pm 0.05 \text{ and } \frac{dt}{t} = \pm 0.025$$

Solve the second of these equations for t to obtain:

$$t = \frac{dt}{0.025} = \frac{1\,\text{s}}{0.025} = 4\,\text{s}$$

Substitute in equation (2) to obtain:

$$a = \frac{2(3\,\text{m})}{(4\,\text{s})^2} = 0.375\,\text{m/s}^2$$

Solve equation (1) for m_2 to obtain:

$$m_2 = \frac{g - a}{g + a}m_1$$

Evaluate m_2 with m_1 = 1 kg:

$$m_2 = \frac{9.81\,\text{m/s}^2 - 0.375\,\text{m/s}^2}{9.81\,\text{m/s}^2 + 0.375\,\text{m/s}^2}(1\,\text{kg})$$

$$= 0.926\,\text{kg}$$

Solve equation (1) for m_1 to obtain:

$$m_1 = m_2\frac{g + a}{g - a}$$

Substitute numerical values to obtain:

$$m_1 = (0.926\,\text{kg})\frac{9.81\,\text{m/s}^2 + 0.375\,\text{m/s}^2}{9.81\,\text{m/s}^2 - 0.375\,\text{m/s}^2}$$

$$= 1.08\,\text{kg}$$

Because the masses are interchangeable: $m_2 = \boxed{0.926\,\text{kg or }1.08\,\text{kg}}$

***89** ••

Picture the Problem We can reason to this conclusion as follows: In the two extreme cases when the mass on one side or the other is zero, the tension is zero as well, because the mass is in free-fall. By symmetry, the maximum tension must occur when the masses on each side are equal. An alternative approach that is shown below is to treat the problem as an extreme-value problem.

Express m_2 in terms of M and m_1:

$$m_2 = M - m_1$$

Substitute in the equation from Problem 84 and simplify to obtain:

$$T = \frac{2gm_1(M - m_1)}{m_1 + M - m_1} = 2g\left(m_1 - \frac{m_1^2}{M}\right)$$

Differentiate this expression with respect to m_1 and set the derivative equal to zero for extreme values:

$$\frac{dT}{dm_1} = 2g\left(1 - \frac{2m_1}{M}\right) = 0 \text{ for extreme values}$$

Solve for m_1 to obtain:

$$m_1 = \tfrac{1}{2}M$$

Show that $m_1 = M/2$ is a maximum value by evaluating the second derivative of T with respect to m_1 at $m_1 = M/2$:

$$\frac{d^2T}{dm_1^2} = -\frac{4g}{M} < 0,\text{ independently of } m_1$$

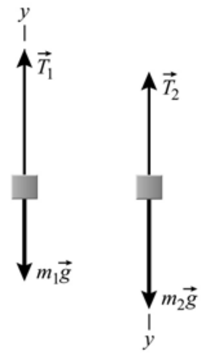
and we have shown that

$$\boxed{T \text{ is a maximum when } m_1 = m_2 = \tfrac{1}{2}M.}$$

Remarks: An alternative solution is to use a graphing calculator to show that *T* as a function of m_1 is concave downward and has its maximum value when $m_1 = m_2 = M/2$.

90 •••

Picture the Problem The free-body diagrams show the forces acting on the objects whose masses are m_1 and m_2. The application of Newton's 2nd law to these forces and the accelerations the net forces are responsible for will lead us to an expression for the tension in the string as a function of m_1 and m_2. Examination of this expression as for $m_2 >> m_1$ will yield the predicted result.



(*a*) Apply $\sum F_y = ma_y$ to the objects whose masses are m_1 and m_2 to obtain:

$$T_1 - m_1g = m_1a_1$$

and

$$m_2g - T_2 = m_2a_2$$

Assume that the role of the pulley is simply to change the direction the tension acts. Then $T_1 = T_2 = T$. Because the two objects have a common acceleration, let $a = a_1 = a_2$. Eliminate a between the two equations and solve for T to obtain:

$$T = \frac{2m_1 m_2}{m_1 + m_2} g$$

Divide the numerator and denominator of this fraction by m_2:

$$T = \frac{2m_1 g}{1 + \dfrac{m_1}{m_2}}$$

Take the limit of this fraction as $m_2 \to \infty$ to obtain:

$$T = \boxed{2m_1 g}$$

(*b*) Imagine the situation when $m_2 >> m_1$:

Under these conditions, the object whose mass is m_2 is essentially in free-fall, so the object whose mass is m_1 is accelerating *upward* with an acceleration of magnitude g.

Under these conditions, the net force acting on the object whose mass is m_1 is $m_1 g$ and:

$T - m_1 g = m_1 g \Rightarrow T = 2m_1 g$.
Note that this result agrees with that obtained using more analytical methods.

General Problems

91 •

Picture the Problem Choose a coordinate system in which the force the tree exerts on the woodpecker's head is in the negative-x direction and determine the acceleration of the woodpecker's head from Newton's 2nd law of motion. The depth of penetration, under the assumption of constant acceleration, can be determined using a constant- acceleration equation. Knowing the acceleration of the woodpecker's head and the depth of penetration of the tree, we can calculate the time required to bring the head to rest.

(*a*) Apply $\sum F_x = ma_x$ to the woodpecker's head to obtain:

$$a_x = \frac{\sum F_x}{m} = \frac{-6\,\text{N}}{0.060\,\text{kg}} = \boxed{-100\,\text{m/s}^2}$$

(*b*) Using a constant-acceleration equation, relate the depth-of-penetration into the bark to the acceleration of the woodpecker's head:

$$v^2 = v_0^2 + 2a\Delta x$$

or, because $v = 0$,

$$0 = v_0^2 + 2a\Delta x$$

Solve for and evaluate Δx:

$$\Delta x = \frac{-v_0^2}{2a} = \frac{-(3.5\,\text{m/s})^2}{2(-100\,\text{m/s}^2)} = \boxed{6.13\,\text{cm}}$$

(*c*) Use the definition of acceleration to express the time required for the woodpecker's head to come to rest:

$$\Delta t = \frac{v - v_0}{a}$$

or, because $v = 0$,

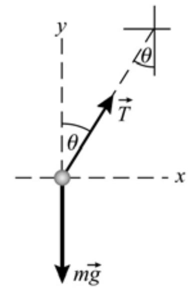
$$\Delta t = \frac{v - v_0}{a}$$

Substitute numerical values and evaluate Δt:

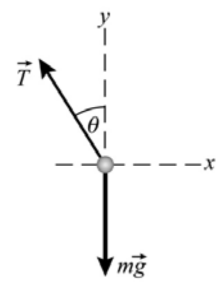
$$\Delta t = \frac{-v_0}{a} = \frac{-3.5\,\text{m/s}}{-100\,\text{m/s}^2} = \boxed{35.0\,\text{ms}}$$

***92 ••**

Picture the Problem The free-body diagram shown to the right shows the forces acting on an object suspended from the ceiling of a car that is accelerating to the right. Choose the coordinate system shown and use Newton's laws of motion and constant- acceleration equations in the determination of the influence of the forces on the behavior of the suspended object.



The second free-body diagram shows the forces acting on an object suspended from the ceiling of a car that is braking while it moves to the right.



(*a*) $\boxed{\text{In accordance with Newton's law of inertia, the object's displacement will be in the direction opposite that of the acceleration.}}$

(*b*) Resolve the tension, T, into its components and apply $\sum \vec{F} = m\vec{a}$ to the object:

$$\Sigma F_x = T\sin\theta = ma$$

and

$$\Sigma F_y = T\cos\theta - mg = 0$$

Take the ratio of these two equations to eliminate T and m:

$$\frac{T\sin\theta}{T\cos\theta} = \frac{ma}{mg}$$

or

$$\tan\theta = \frac{a}{g} \Rightarrow \boxed{a = g\tan\theta}$$

(*c*) $\boxed{\text{Because the acceleration is opposite the direction the car is moving, the accelerometer will swing forward.}}$

Using a constant-acceleration equation, express the velocity of the car in terms of its acceleration and solve for the acceleration:

$$v^2 = v_0^2 + 2a\Delta x$$

or, because $v = 0$,

$$0 = v_0^2 + 2a\Delta x$$

Solve for a:

$$a = \frac{-v_0^2}{2\Delta x}$$

Substitute numerical values and evaluate a:

$$a = \frac{-(50\,\text{km/h})^2}{2(60\,\text{m})} = \boxed{-1.61\,\text{m/s}^2}$$

Solve the equation derived in (*b*) for θ:

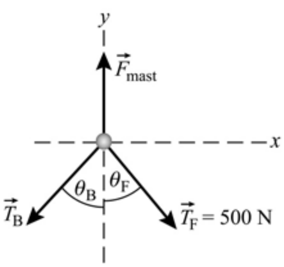
$$\theta = \tan^{-1}\left(\frac{a}{g}\right)$$

Substitute numerical values and evaluate θ:

$$\theta = \tan^{-1}\left(\frac{1.61\,\text{m/s}^2}{9.81\,\text{m/s}^2}\right) = \boxed{9.32°}$$

93 ••

Picture the Problem The free-body diagram shows the forces acting at the top of the mast. Choose the coordinate system shown and use Newton's 2nd and 3rd laws of motion to analyze the forces acting on the deck of the sailboat.



Apply $\sum F_x = ma_x$ to the top of the mast:

$$T_F \sin\theta_F - T_B \sin\theta_B = 0$$

Find the angles that the forestay and backstay make with the vertical:

$$\theta_F = \tan^{-1}\left(\frac{3.6\,\text{m}}{12\,\text{m}}\right) = 16.7°$$

and

$$\theta_B = \tan^{-1}\left(\frac{6.4\,\text{m}}{12\,\text{m}}\right) = 28.1°$$

Solve the x-direction equation for T_B:

$$T_B = T_F \frac{\sin\theta_F}{\sin\theta_B} = (500\,\text{N})\frac{\sin 16.7°}{\sin 28.1°} = \boxed{305\,\text{N}}$$

Find the downward forces that T_B and T_F exert on the mast:

$$\sum F_y = F_{mast} - T_F \cos\theta_F - T_B \cos\theta_B = 0$$

Solve for F_{mast} to obtain:

$$F_{mast} = T_F \cos\theta_F + T_B \cos\theta_B$$

Substitute numerical values and evaluate F_{mast}:

$$F_{\text{mast}} = (500\text{ N})\cos 16.7° + (305\text{ N})\cos 28.1° = 748\text{ N}$$

The force that the mast exerts on the deck is the sum of its weight and the downward forces exerted on it by the forestay and backstay:

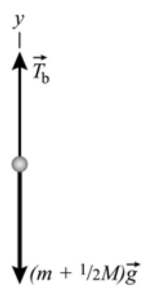
$$F_{\text{mast on the deck}} = 748\text{ N} + 800\text{ N}$$
$$= \boxed{1.55\text{ kN}}$$

94 ••

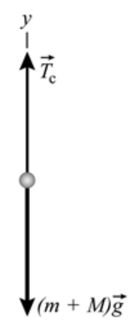
Picture the Problem Let m be the mass of the block and M be the mass of the chain. The free-body diagrams shown below display the forces acting at the locations identified in the problem. We can apply Newton's 2nd law with $a_y = 0$ to each of the segments of the chain to determine the tensions.

(*a*)

(*b*)



(*c*)



(*a*) Apply $\sum F_y = ma_y$ to the block and solve for T_a:

$$T_a - mg = ma_y$$
or, because $a_y = 0$,
$$T_a = mg$$

Substitute numerical values and evaluate T_a:

$$T_a = (50\text{ kg})(9.81\text{ m/s}^2) = \boxed{491\text{ N}}$$

(*b*) Apply $\sum F_y = ma_y$ to the block and half the chain and solve for T_b:

$$T_b - \left(m + \frac{M}{2}\right)g = ma_y$$
or, because $a_y = 0$,
$$T_b = \left(m + \frac{M}{2}\right)g$$

Substitute numerical values and evaluate T_b:

$$T_b = (50\text{ kg} + 10\text{ kg})(9.81\text{ m/s}^2) = \boxed{589\text{ N}}$$

(*c*) Apply $\sum F_y = ma_y$ to the block and chain and solve for T_c:

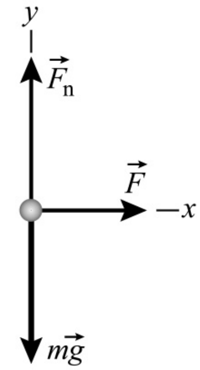
$$T_c - (m + M)g = ma_y$$
or, because $a_y = 0$,
$$T_c = (m + M)g$$

Substitute numerical values and evaluate T_c:

$$T_c = (50\,\text{kg} + 20\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{687\,\text{N}}$$

***95 •••**

Picture the Problem The free-body diagram shows the forces acting on the box as the man pushes it across a frictionless floor. Because the force is time-dependent, the acceleration will be, too. We can obtain the acceleration as a function of time from the application of Newton's 2nd law and then find the velocity of the box as a function of time by integration. Finally, we can derive an expression for the displacement of the box as a function of time by integration of the velocity function.



(*a*) The velocity is related to the acceleration according to:

$$\frac{dv}{dt} = a(t) \qquad (1)$$

Apply $\sum F_x = ma_x$ to the box and solve for its acceleration:

$$F = ma$$

and

$$a = \frac{F}{m} = \frac{(8\,\text{N/s})t}{24\,\text{kg}} = \left(\tfrac{1}{3}\,\text{m/s}^3\right)t$$

Because the box's acceleration is a function of time, separate variables in equation (1) and integrate to find v as a function of time:

$$v(t) = \int_0^t a(t')dt' = \left(\tfrac{1}{3}\,\text{m/s}^3\right)\int_0^t t'\,dt' = \left(\tfrac{1}{3}\,\text{m/s}^3\right)\frac{t^2}{2} = \left(\tfrac{1}{6}\,\text{m/s}^3\right)t^2$$

Evaluate v at $t = 3$ s:

$$v(3\,\text{s}) = \left(\tfrac{1}{6}\,\text{m/s}^3\right)(3\,\text{s})^2 = \boxed{1.50\,\text{m/s}}$$

(*b*) Integrate $v = dx/dt$ between 0 and 3 s to find the displacement of the box during this time:

$$\Delta x = \int_0^{3\,\text{s}} v(t')dt' = \left(\tfrac{1}{6}\,\text{m/s}^3\right)\int_0^{3\,\text{s}} t'^2\,dt' = \left[\left(\tfrac{1}{6}\,\text{m/s}^3\right)\frac{t'^3}{3}\right]_0^{3\,\text{s}} = \boxed{1.50\,\text{m}}$$

(*c*) The average velocity is given by:

$$v_\text{ave} = \frac{\Delta x}{\Delta t} = \frac{1.5\,\text{m}}{3\,\text{s}} = \boxed{0.500\,\text{m/s}}$$

(*d*) Use Newton's 2nd law to express the average force exerted on the box by the man:

$$F_\text{av} = ma_\text{av} = m\frac{\Delta v}{\Delta t}$$

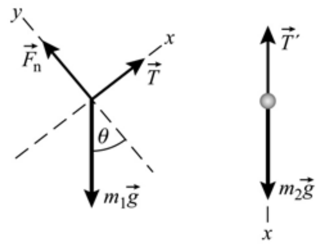
Substitute numerical values and evaluate F_{av}:

$$F_{av} = (24\,\text{kg})\frac{1.5\,\text{m/s} - 0\,\text{m/s}}{3\text{s}} = \boxed{12.0\,\text{N}}$$

96 ••

Picture the Problem The application of Newton's 2nd law to the glider and the hanging weight will lead to simultaneous equations in their common acceleration *a* and the tension *T* in the cord that connects them. Once we know the acceleration of this system, we can use a constant-acceleration equation to predict how long it takes the cart to travel 1 m from rest. Note that the magnitudes of $\vec{T}$ and $\vec{T}'$ are equal.

(*a*) The free-body diagrams are shown to the right. m_1 represents the mass of the cart and m_2 the mass of the hanging weight.



(*b*) Apply $\sum F_x = ma_x$ to the cart and the suspended mass:

$$T - m_1 g\sin\theta = m_1 a_1$$
and
$$m_2 g - T = m_2 a_2$$

Letting *a* represent the common accelerations of the two objects, eliminate *T* between the two equations and solve *a*:

$$a = \frac{m_2 - m_1\sin\theta}{m_1 + m_2}g$$

Substitute numerical values and evaluate *a*:

$$a = \frac{0.075\,\text{kg} - (0.270\,\text{kg})\sin 30°}{0.075\,\text{kg} + 0.270\,\text{kg}} \times (9.81\,\text{m/s}^2) = \boxed{-1.71\,\text{m/s}^2}$$

i.e., the acceleration is down the incline.

Substitute for *a* in either of the force equations to obtain:

$$T = \boxed{0.863\,\text{N}}$$

(*c*) Using a constant-acceleration equation, relate the displacement of the cart down the incline to its initial speed and acceleration:

$$\Delta x = v_0\Delta t + \tfrac{1}{2}a(\Delta t)^2$$
or, because $v_0 = 0$,
$$\Delta x = \tfrac{1}{2}a(\Delta t)^2$$

Solve for Δt:

$$\Delta t = \sqrt{\frac{2\Delta x}{a}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \sqrt{\frac{2(1\,\text{m})}{1.71\,\text{m/s}^2}} = \boxed{1.08\,\text{s}}$$

97 ••

Picture the Problem Note that, while the mass of the rope is distributed over its length, the rope and the block have a common acceleration. Because the surface is horizontal and smooth, the only force that influences our solution is $\vec{F}$. The figure misrepresents the situation in that each segment of the rope experiences a gravitational force; the combined effect of which is that the rope must sag.

(*a*) Apply $\vec{a} = \vec{F}_{\text{net}}/m_{\text{tot}}$ to the rope-block system to obtain:

$$a = \boxed{\frac{F}{m_1 + m_2}}$$

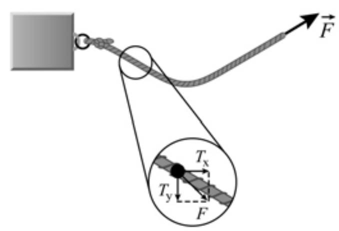
(*b*) Apply $\sum \vec{F} = m\vec{a}$ to the rope, substitute the acceleration of the system obtained in (*a*), and simplify to obtain:

$$F_{\text{net}} = m_2 a = m_2\left(\frac{F}{m_1 + m_2}\right) = \boxed{\frac{m_2}{m_1 + m_2}F}$$

(*c*) Apply $\sum \vec{F} = m\vec{a}$ to the block, substitute the acceleration of the system obtained in (*a*), and simplify to obtain:

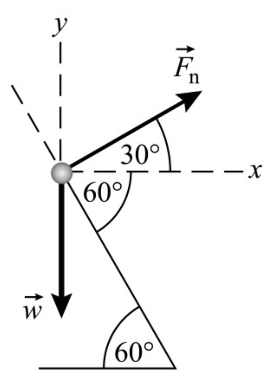
$$T = m_1 a = m_1\left(\frac{F}{m_1 + m_2}\right) = \boxed{\frac{m_1}{m_1 + m_2}F}$$

(*d*) The rope sags and so $\vec{F}$ has both vertical and horizontal components; with its horizontal component being less than $\vec{F}$. Consequently, *a* will be somewhat smaller.



***98 ••**

Picture the Problem The free-body diagram shows the forces acting on the block. Choose the coordinate system shown on the diagram. Because the surface of the wedge is frictionless, the force it exerts on the block must be normal to its surface.



(*a*) Apply $\sum F_y = ma_y$ to the block to obtain:

$$F_n \sin 30° - w = ma_y$$

or, because $a_y = 0$ and $w = mg$,

$$F_n \sin 30° - mg = 0$$

or

$$F_n \sin 30° = mg \qquad (1)$$

Apply $\sum F_x = ma_x$ to the block:

$$F_n \cos 30° = ma_x \qquad (2)$$

Divide equation (2) by equation (1) to obtain:

$$\frac{a_x}{g} = \cot 30°$$

Solve for and evaluate a_x:

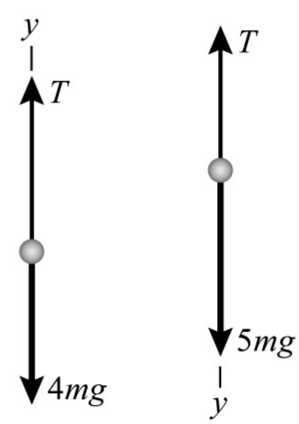
$$a_x = g \cot 30° = (9.81\,\text{m/s}^2)\cot 30° = \boxed{17.0\,\text{m/s}^2}$$

(*b*) An acceleration of the wedge greater than $g \cot 30°$ would require that the normal force exerted on the body by the wedge be greater than that given in part (*a*); i.e., $F_n > mg/\sin 30°$.

Under this condition, there would be a net force in the y direction and the block would accelerate up the wedge.

99 ••

Picture the Problem Because the system is initially in equilibrium, it follows that $T_0 = 5mg$. When one washer is removed on the left side, the remaining washers will accelerate upward (and those on the right side downward) in response to the net force that results. The free-body diagrams show the forces under this unbalanced condition. Applying Newton's 2nd law to each collection of washers will allow us to determine both the acceleration of the system and the mass of a single washer.



(*a*) Apply $\sum F_y = ma_y$ to the rising masses:

$$T - 4mg = (4m)a \qquad (1)$$

Apply $\sum F_y = ma_y$ to the descending masses:

$$5mg - T = (5m)a \qquad (2)$$

Eliminate T between these equations to obtain:

$$a = \tfrac{1}{9}g$$

Use this acceleration in equation (1) or equation (2) to obtain:

$$T = \frac{40}{9}mg$$

Express the difference between T_0 and T and solve for m:

$$T_0 - T = 5mg - \frac{40}{9}mg = 0.3\,\text{N}$$

and

$m = \boxed{0.0550\,\text{kg} = 55.0\,\text{g}}$

(*b*) Proceed as in (*a*) to obtain:

$T - 3mg = 3ma$
and
$5mg - T = 5ma$

Eliminate T and solve for a:

$a = \frac{1}{4}g = \frac{1}{4}(9.81\,\text{m/s}^2) = \boxed{2.45\,\text{m/s}^2}$

Eliminate a in either of the motion equations and solve for T to obtain:

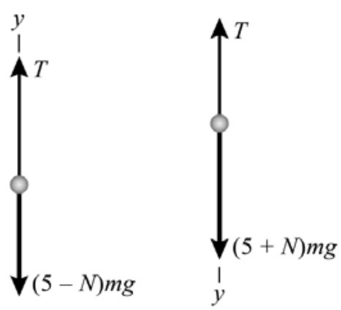
$$T = \frac{15}{4}mg$$

Substitute numerical values and evaluate T:

$$T = \frac{15}{4}(0.0550\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{2.03\,\text{N}}$$

100 ••

Picture the Problem The free-body diagram represents the Atwood's machine with N washers moved from the left side to the right side. Application of Newton's 2nd law to each collection of washers will result in two equations that can be solved simultaneously to relate N, a, and g. The acceleration can then be found from the given data.



Apply $\sum F_y = ma_y$ to the rising washers:

$T - (5 - N)mg = (5 - N)ma$

Apply $\sum F_y = ma_y$ to the descending washers:

$(5 + N)mg - T = (5 + N)ma$

Add these equations to eliminate T:

$$(5 + N)mg - (5 - N)mg = (5 - N)ma + (5 + N)ma$$

Simplify to obtain:

$2Nmg = 10ma$

Solve for N:

$N = 5a/g$

Using a constant-acceleration equation, relate the distance the washers fell to their time of fall:

$\Delta y = v_0\Delta t + \frac{1}{2}a(\Delta t)^2$
or, because $v_0 = 0$,
$\Delta y = \frac{1}{2}a(\Delta t)^2$

Solve for the acceleration:

$$a = \frac{2\Delta y}{(\Delta t)^2}$$

Substitute numerical values and evaluate a:

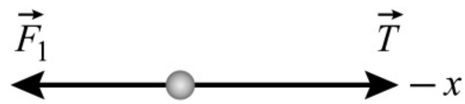
$$a = \frac{2(0.471\,\text{m})}{(0.40\,\text{s})^2} = 5.89\,\text{m/s}^2$$

Substitute in the expression for N:

$$N = 5\left(\frac{5.89\,\text{m/s}^2}{9.81\,\text{m/s}^2}\right) = \boxed{3}$$

101 ••

Picture the Problem Draw the free-body diagram for the block of mass m and apply Newton's 2nd law to obtain the acceleration of the system and then the tension in the rope connecting the two blocks.



(a) Letting T be the tension in the connecting string, apply $\sum F_x = ma_x$ to the block of mass m:

$$T - F_1 = ma$$

Apply $\sum F_x = ma_x$ to both blocks to determine the acceleration of the system:

$$F_2 - F_1 = (m + 2m)a = (3m)a$$

Substitute and solve for a:

$$a = (F_2 - F_1)/3m$$

Substitute for a in the first equation and solve for T:

$$T = \boxed{\tfrac{1}{3}(F_2 + 2F_1)}$$

(b) Substitute for F_1 and F_2 in the equation derived in part (a):

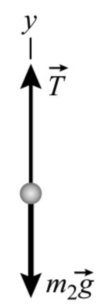
$$T = (2Ct + 2Ct)/3 = 4Ct/3$$

Evaluate this expression for $T = T_0$ and $t = t_0$ and solve for t_0:

$$t_0 = \boxed{\frac{3T_0}{4C}}$$

***102** •••

Picture the Problem Because a constant-upward acceleration has the same effect as an increase in the acceleration due to gravity, we can use the result of Problem 89 (for the tension) with a replaced by $a + g$. The application of Newton's 2nd law to the object whose mass is m_2 will connect the acceleration of this body to tension from Problem 84.



In Problem 84 it is given that, when the support pulley is not accelerating, the tension in the rope and the acceleration of the masses are related according to:

$$T = \frac{2m_1m_2}{m_1 + m_2}g$$

Replace a with $a + g$:

$$T = \frac{2m_1m_2}{m_1 + m_2}(a + g)$$

Apply $\sum F_y = ma_y$ to the object whose mass is m_2 and solve for a_2:

$$T - m_2g = m_2a_2$$

and

$$a_2 = \frac{T - m_2g}{m_2}$$

Substitute for T and simplify to obtain:

$$\boxed{a_2 = \frac{(m_1 - m_2)g + 2m_1a}{m_1 + m_2}}$$

The expression for a_1 is the same as for a_2 with all subscripts interchanged (note that a positive value for a_1 represents acceleration upward):

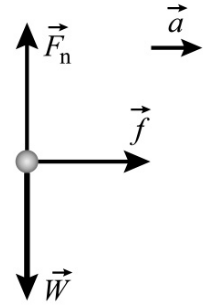
$$\boxed{a_1 = \frac{(m_2 - m_1)g + 2m_2a}{m_1 + m_2}}$$

Chapter 5
Applications of Newton's Laws

Conceptual Problems

1 •

Determine the Concept Because the objects are speeding up (accelerating), there must be a net force acting on them. The forces acting on an object are the normal force exerted by the floor of the truck, the weight of the object, and the friction force; also exerted by the floor of the truck.

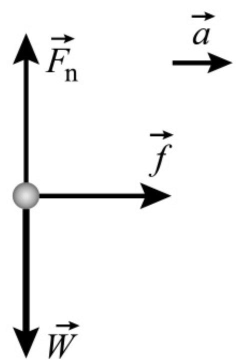


Of these forces, the only one that acts in the direction of the acceleration (chosen to be to the right in the free-body diagram) is the friction force.

The force of friction between the object and the floor of the truck must be the force that causes the object to accelerate.

***2** •

Determine the Concept The forces acting on an object are the normal force exerted by the floor of the truck, the weight of the object, and the friction force; also exerted by the floor of the truck. Of these forces, the only one that acts in the direction of the acceleration (chosen to be to the right in the free-body diagram) is the friction force. Apply Newton's 2nd law to the object to determine how the critical acceleration depends on its weight.



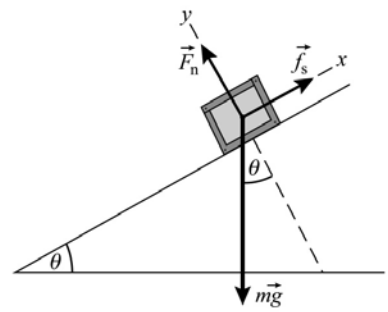
Taking the positive x direction to be to the right, apply $\Sigma F_x = ma_x$ and solve for a_x:

$$f = \mu_s w = \mu_s mg = ma_x$$
and
$$a_x = \mu_s g$$

Because a_x is independent of m and w, the critical accelerations are the same.

3 •

Determine the Concept The forces acting on the block are the normal force $\vec{F}_n$ exerted by the incline, the weight of the block $m\vec{g}$ exerted by the earth, and the static friction force $\vec{f}_s$ exerted by an external agent. We can use the definition of μ_s and the conditions for equilibrium to determine the relationship between μ_s and θ.



Apply $\sum F_x = ma_x$ to the block: $f_s - mg\sin\theta = 0$ (1)

Apply $\sum F_y = ma_y$ in the y direction: $F_n - mg\cos\theta = 0$ (2)

Divide equation (1) by equation (2) to obtain: $\tan\theta = \dfrac{f_s}{F_n}$

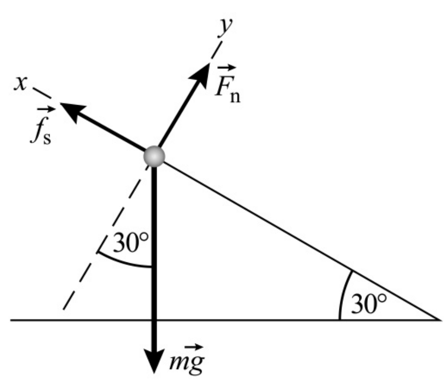
Substitute for f_s ($\le \mu_s F_n$): $\tan\theta \le \dfrac{\mu_s F_n}{F_n} = \mu_s$

and $\boxed{(d) \text{ is correct.}}$

***4** •

Determine the Concept The block is in equilibrium under the influence of $\vec{F}_n$, $m\vec{g}$, and $\vec{f}_s$; i.e.,

$$\vec{F}_n + m\vec{g} + \vec{f}_s = 0$$



We can apply Newton's 2nd law in the x direction to determine the relationship between f_s and mg.

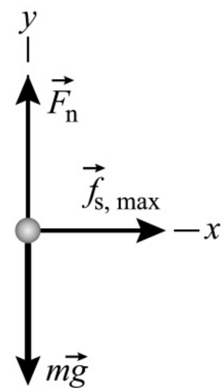
Apply $\sum F_x = 0$ to the block: $f_s - mg\sin\theta = 0$

Solve for f_s: $f_s = mg\sin\theta$

and $\boxed{(d) \text{ is correct.}}$

5 ••

Picture the Problem The forces acting on the car as it rounds a curve of radius R at maximum speed are shown on the free-body diagram to the right. The centripetal force is the static friction force exerted by the roadway on the tires. We can apply Newton's 2nd law to the car to derive an expression for its maximum speed and then compare the speeds under the two friction conditions described.



Apply $\sum \vec{F} = m\vec{a}$ to the car:

$$\sum F_x = f_{s,max} = m\frac{v_{max}^2}{R}$$

and

$$\sum F_y = F_n - mg = 0$$

From the y equation we have: $F_n = mg$

Express $f_{s,max}$ in terms of F_n in the x equation and solve for v_{max}:

$$v_{max} = \sqrt{\mu_s gR}$$

or

$$v_{max} = \text{constant}\sqrt{\mu_s}$$

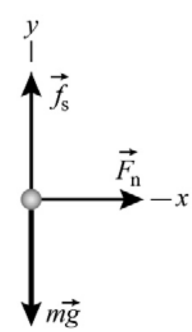
Express v'_{max} for $\mu'_s = \frac{1}{2}\mu_s$:

$$v'_{max} = \text{constant}\sqrt{\frac{\mu_s}{2}} = .707v_{max} \approx 71\%v_{max}$$

and $\boxed{(b) \text{ is correct.}}$

***6 ••**

Picture the Problem The normal reaction force F_n provides the centripetal force and the force of static friction, $\mu_s F_n$, keeps the cycle from sliding down the wall. We can apply Newton's 2nd law and the definition of $f_{s,max}$ to derive an expression for v_{min}.



Apply $\sum \vec{F} = m\vec{a}$ to the motorcycle:

$$\sum F_x = F_n = m\frac{v^2}{R}$$

and

$$\sum F_y = f_s - mg = 0$$

For the minimum speed: $f_s = f_{s,max} = \mu_s F_n$

Substitute for f_s, eliminate F_n between the force equations, and solve for v_{min}:

$$v_{min} = \sqrt{\frac{Rg}{\mu_s}}$$

Assume that $R = 6$ m and $\mu_s = 0.8$ and solve for v_{min}:

$$v_{min} = \sqrt{\frac{(6\,\text{m})(9.81\,\text{m/s}^2)}{0.8}} = \boxed{8.58\,\text{m/s} = 30.9\,\text{km/h}}$$

7 ••

Determine the Concept As the spring is extended, the force exerted by the spring on the block increases. Once that force is greater than the maximum value of the force of static friction on the block, the block will begin to move. However, as it accelerates, it will shorten the length of the spring, decreasing the force that the spring exerts on the block. As this happens, the force of kinetic friction can then slow the block to a stop, which starts the cycle over again. One interesting application of this to the real world is the bowing of a violin string: The string under tension acts like the spring, while the bow acts as the block, so as the bow is dragged across the string, the string periodically sticks and frees itself from the bow.

8 •

True. The velocity of an object moving in a circle is continually changing independently of whether the object's speed is changing. The change in the velocity vector and the acceleration vector and the net force acting on the object all point toward the center of circle. This center-pointing force is called a centripetal force.

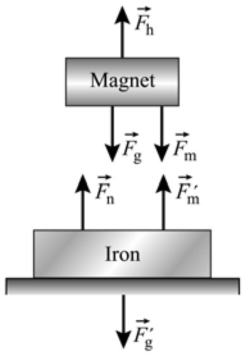
9 •

Determine the Concept A particle traveling in a vertical circle experiences a downward gravitational force plus an additional force that constrains it to move along a circular path. Because the net force acting on the particle will vary with location along its trajectory, neither (*b*), (*c*), nor (*d*) can be correct. Because the velocity of a particle moving along a circular path is continually changing, (*a*) cannot be correct. $\boxed{(e)\text{ is correct.}}$

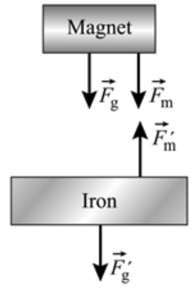
***10** •

Determine the Concept We can analyze these demonstrations by drawing force diagrams for each situation. In both diagrams, h denotes ″hand″, g denotes ″gravitational″, m denotes ″magnetic″, and n denotes ″normal″.

(*a*) Demonstration 1:



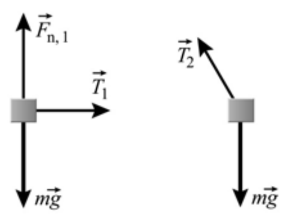
Demonstration 2:



(*b*) Because the magnet doesn't lift the iron in the first demonstration, the force exerted on the iron must be less than its (the iron's) weight. This is still true when the two are falling, but the motion of the iron is not restrained by the table, and the motion of the magnet is not restrained by the hand. Looking at the second diagram, the net force pulling the magnet down is greater than its weight, implying that its acceleration is greater than g. The opposite is true for the iron: the magnetic force acts upwards, slowing it down, so its acceleration will be less than g. Because of this, the magnet will catch up to the iron piece as they fall.

***11 •••**

Picture the Problem The free-body diagrams show the forces acting on the two objects some time after block 2 is dropped. Note that, while $\vec{T}_1 \neq \vec{T}_2$, $T_1 = T_2$.



The only force pulling block 2 to the left is the horizontal component of the tension. Because this force is smaller than the magnitude of the tension, the acceleration of block 1, which is identical to block 2, to the right ($T_1 = T_2$) will always be greater than the acceleration of block 2 to the left.

Because the initial distance from block 1 to the pulley is the same as the initial distance of block 2 to the wall, block 1 will hit the pulley before block 2 hits the wall.

12 •

True. The terminal speed of an object is given by $v_t = (mg/b)^{1/n}$, where b depends on the shape and area of the falling object as well as upon the properties of the medium in which the object is falling.

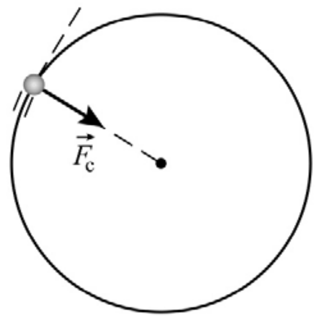
13 •

Determine the Concept The terminal speed of a sky diver is given by $v_t = (mg/b)^{1/n}$, where b depends on the shape and area of the falling object as well as upon the properties of the medium in which the object is falling. The sky diver's orientation as she falls determines the surface area she presents to the air molecules that must be pushed aside.

$\boxed{(d) \text{ is correct.}}$

14 ••

Determine the Concept In your frame of reference (the accelerating reference frame of the car), the direction of the force must point toward the center of the circular path along which you are traveling; that is, in the direction of the centripetal force that keeps you moving in a circle. The friction between you and the seat you are sitting on supplies this force. The reason you seem to be "pushed" to the outside of the curve is that your body's inertia "wants" , in accordance with Newton's law of inertia, to keep it moving in a straight line–that is, tangent to the curve.



***15 •**

Determine the Concept The centripetal force that keeps the moon in its orbit around the earth is provided by the gravitational force the earth exerts on the moon. As described by Newton's 3rd law, this force is equal in magnitude to the force the moon exerts on the earth. $\boxed{(d) \text{ is correct.}}$

16 •

Determine the Concept The only forces acting on the block are its weight and the force the surface exerts on it. Because the loop-the-loop surface is frictionless, the force it exerts on the block must be perpendicular to its surface.

Point A: the weight is downward and the normal force is to the right.	Free-body diagram 3
Point B: the weight is downward, the normal force is upward, and the normal force is greater than the weight so that their difference is the centripetal force.	Free-body diagram 4
Point C: the weight is downward and the normal force is to the left.	Free-body diagram 5
Point D: both the weight and the normal forces are downward.	Free-body diagram 2

17 ••

Picture the Problem Assume that the drag force on an object is given by the Newtonian formula $F_D = \frac{1}{2}CA\rho v^2$, where A is the projected surface area, v is the object's speed, ρ is the density of air, and C a dimensionless coefficient.

Express the net force acting on the falling object:

$$F_{net} = mg - F_D = ma$$

Substitute for F_D under terminal speed conditions and solve for the terminal speed:

$$mg - \frac{1}{2}CA\rho v_T^2 = 0$$

or

$$v_T = \sqrt{\frac{2mg}{CA\rho}}$$

Thus, the terminal velocity depends on the ratio of the mass of the object to its surface area.

For a rock, which has a relatively small surface area compared to its mass, the terminal speed will be relatively high; for a lightweight, spread-out object like a feather, the opposite is true.

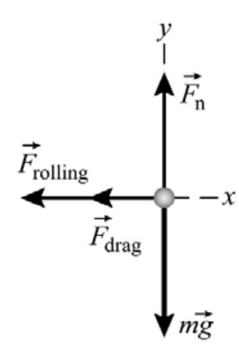
Another issue is that the higher the terminal velocity is, the longer it takes for a falling object to reach terminal velocity. From this, the feather will reach its terminal velocity quickly, and fall at an almost constant speed very soon after being dropped; a rock, if not dropped from a great height, will have almost the same acceleration as if it were in free-fall for the duration of its fall, and thus be continually speeding up as it falls.

An interesting point is that the average drag force acting on the rock will be larger than that acting on the feather precisely *because* the rock's average speed is larger than the feather's, as the drag force increases as v^2. This is another reminder that force is not the same thing as acceleration.

Estimation and Approximation

***18 •**

Picture the Problem The free-body diagram shows the forces on the Tercel as it slows from 60 to 55 mph. We can use Newton's 2nd law to calculate the average force from the rate at which the car's speed decreases and the rolling force from its definition. The drag force can be inferred from the average and rolling friction forces and the drag coefficient from the defining equation for the drag force.



(*a*) Apply $\sum F_x = ma_x$ to the car to relate the average force acting on it to its average velocity:

$$F_{av} = ma_{av} = m\frac{\Delta v}{\Delta t}$$

Substitute numerical values and evaluate F_{av}:

$$F_{\text{av}} = (1020\,\text{kg})\frac{5\dfrac{\text{mi}}{\text{h}}\times 1.609\dfrac{\text{km}}{\text{mi}}\times\dfrac{1\,\text{h}}{3600\,\text{s}}\times\dfrac{1000\,\text{m}}{\text{km}}}{3.92\,\text{s}} = \boxed{581\,\text{N}}$$

(*b*) Using its definition, express and evaluate the force of rolling friction:

$$f_{\text{rolling}} = \mu_{\text{rolling}}F_{\text{n}} = \mu_{\text{rolling}}mg$$
$$= (0.02)(1020\,\text{kg})(9.81\,\text{m/s}^2)$$
$$= \boxed{200\,\text{N}}$$

Assuming that only two forces are acting on the car in the direction of its motion, express their relationship and solve for and evaluate the drag force:

$$F_{\text{av}} = F_{\text{drag}} + F_{\text{rolling}}$$
and
$$F_{\text{drag}} = F_{\text{av}} - F_{\text{rolling}}$$
$$= 581\,\text{N} - 200\,\text{N} = \boxed{381\,\text{N}}$$

(*c*) Convert 57.5 mi/h to m/s:

$$57.5\frac{\text{mi}}{\text{h}} = 57.5\frac{\text{mi}}{\text{h}}\times\frac{1.609\,\text{km}}{\text{mi}}$$
$$\times\frac{1\,\text{h}}{3600\,\text{s}}\times\frac{10^3\,\text{m}}{\text{km}}$$
$$= 25.7\,\text{m/s}$$

Using the definition of the drag force and its calculated value from (*b*) and the average speed of the car during this 5 mph interval, solve for *C*:

$$F_{\text{drag}} = \tfrac{1}{2}C\rho Av^2 \Rightarrow C = \frac{2F_{\text{drag}}}{\rho Av^2}$$

Substitute numerical values and evaluate *C*:

$$C = \frac{2(381\,\text{N})}{(1.21\,\text{kg/m}^3)(1.91\,\text{m}^2)(25.7\,\text{m/s})^2}$$
$$= \boxed{0.499}$$

19 •

Picture the Problem We can use the dimensions of force and velocity to determine the dimensions of the constant *b* and the dimensions of ρ, r, and v to show that, for $n = 2$, Newton's expression is consistent dimensionally with our result from part (*b*). In parts (*d*) and (*e*), we can apply Newton's 2nd law under terminal velocity conditions to find the terminal velocity of the sky diver near the surface of the earth and at a height of 8 km.

(*a*) Solve the drag force equation for *b* with $n = 1$:

$$b = \frac{F_{\text{d}}}{v}$$

Substitute the dimensions of F_d and v and simplify to obtain:

$$[b] = \frac{\frac{ML}{T^2}}{\frac{L}{T}} = \boxed{\frac{M}{T}}$$

and the units of b are $\boxed{\text{kg/s}}$

(*b*) Solve the drag force equation for b with $n = 2$:

$$b = \frac{F_d}{v^2}$$

Substitute the dimensions of F_d and v and simplify to obtain:

$$[b] = \frac{\frac{ML}{T^2}}{\left(\frac{L}{T}\right)^2} = \boxed{\frac{M}{L}}$$

and the units of b are $\boxed{\text{kg/m}}$

(*c*) Express the dimensions of Newton's expression:

$$[F_d] = \left[\tfrac{1}{2}\rho\pi r^2 v^2\right] = \left(\frac{M}{L^3}\right)(L)^2\left(\frac{L}{T}\right)^2$$

$$= \boxed{\frac{ML}{T^2}}$$

From part (*b*) we have:

$$[F_d] = \left[bv^2\right] = \left(\frac{M}{L}\right)\left(\frac{L}{T}\right)^2$$

$$= \boxed{\frac{ML}{T^2}}$$

(*d*) Letting the downward direction be the positive y direction, apply $\sum F_y = ma_y$ to the sky diver:

$$mg - \tfrac{1}{2}\rho\pi r^2 v_t^2 = 0$$

Solve for and evaluate v_t:

$$v_t = \sqrt{\frac{2mg}{\rho\pi r^2}} = \sqrt{\frac{2(56\,\text{kg})(9.81\,\text{m/s}^2)}{\pi(1.2\,\text{kg/m}^3)(0.3\,\text{m})^2}}$$

$$= \boxed{56.9\,\text{m/s}}$$

(*e*) Evaluate v_t at a height of 8 km:

$$v_t = \sqrt{\frac{2(56\,\text{kg})(9.81\,\text{m/s}^2)}{\pi(0.514\,\text{kg/m}^3)(0.3\,\text{m})^2}}$$

$$= \boxed{86.9\,\text{m/s}}$$

20 ••

Picture the Problem From Newton's 2nd law, the equation describing the motion of falling raindrops and large hailstones is $mg - F_d = ma$ where $F_d = \frac{1}{2}\rho\pi r^2 v^2 = bv^2$ is the drag force. Under terminal speed conditions ($a = 0$), the drag force is equal to the weight of the falling object. Take the radius of a raindrop r_r to be 0.5 mm and the radius of a golf-ball sized hailstone r_h to be 2 cm.

Using $b = \frac{1}{2}\pi\rho r^2$, evaluate b_r and b_h:

$$b_r = \tfrac{1}{2}\pi(1.2\,\text{kg/m}^3)(0.5\times10^{-3}\,\text{m})^2 = 4.71\times10^{-7}\,\text{kg/m}$$

and

$$b_h = \tfrac{1}{2}\pi(1.2\,\text{kg/m}^3)(2\times10^{-2}\,\text{m})^2 = 7.54\times10^{-4}\,\text{kg/m}$$

Express the mass of a sphere in terms of its volume and density:

$$m = \rho V = \frac{4\pi r^3\rho}{3}$$

Using $\rho_r = 10^3$ kg/m^3 and $\rho_h = 920$ kg/m^3, evaluate m_r and m_h:

$$m_r = \frac{4\pi(0.5\times10^{-3}\,\text{m})^3(10^3\,\text{kg/m}^3)}{3} = 5.24\times10^{-7}\,\text{kg}$$

and

$$m_h = \frac{4\pi(2\times10^{-2}\,\text{m})^3(920\,\text{kg/m}^3)}{3} = 3.08\times10^{-2}\,\text{kg}$$

Express the relationship between v_t and the weight of a falling object under terminal speed conditions and solve for v_t:

$$bv_t^2 = mg \Rightarrow v_t = \sqrt{\frac{mg}{b}}$$

Use numerical values to evaluate $v_{t,r}$ and $v_{t,h}$:

$$v_{t,r} = \sqrt{\frac{(5.24\times10^{-7}\,\text{kg})(9.81\,\text{m/s}^2)}{4.71\times10^{-7}\,\text{kg/m}}} = \boxed{3.30\,\text{m/s}}$$

and

$$v_{t,h} = \sqrt{\frac{(3.08\times10^{-2}\,\text{kg})(9.81\,\text{m/s}^2)}{7.54\times10^{-4}\,\text{kg/m}}} = \boxed{20.0\,\text{m/s}}$$

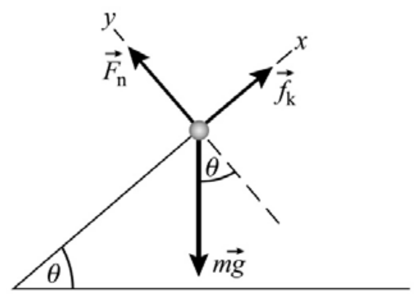
Friction

***21** •

Picture the Problem The block is in equilibrium under the influence of $\vec{F}_n$, $m\vec{g}$, and $\vec{f}_k$; i.e.,

$$\vec{F}_n + m\vec{g} + \vec{f}_k = 0$$

We can apply Newton's 2nd law to determine the relationship between f_k, θ, and mg.



Using its definition, express the coefficient of kinetic friction:

$$\mu_k = \frac{f_k}{F_n} \qquad (1)$$

Apply $\sum F_x = ma_x$ to the block: $f_k - mg\sin\theta = ma_x = 0$ because $a_x = 0$

Solve for f_k: $f_k = mg\sin\theta$

Apply $\sum F_y = ma_y$ to the block: $F_n - mg\cos\theta = ma_y = 0$ because $a_y = 0$

Solve for F_n: $F_n = mg\cos\theta$

Substitute in equation (1) to obtain:

$$\mu_k = \frac{mg\sin\theta}{mg\cos\theta} = \tan\theta$$

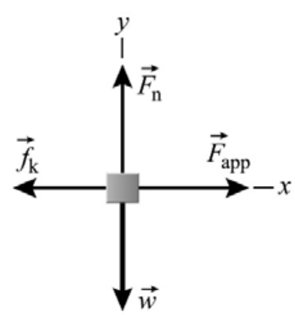
and **(b) is correct.**

22 •

Picture the Problem The block is in equilibrium under the influence of $\vec{F}_n$, $m\vec{g}$, $\vec{F}_{app}$, and $\vec{f}_k$; i.e.,

$$\vec{F}_n + m\vec{g} + \vec{F}_{app} + \vec{f}_k = 0$$

We can apply Newton's 2nd law to determine f_k.



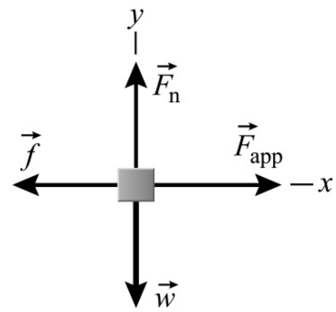
Apply $\sum F_x = ma_x$ to the block: $F_{app} - f_k = ma_x = 0$ because $a_x = 0$

Solve for f_k: $f_k = F_{app} = 20\ \text{N}$

and **(e) is correct.**

***23 •**

Picture the Problem Whether the friction force is that due to static friction or kinetic friction depends on whether the applied tension is greater than the maximum static friction force. We can apply the definition of the maximum static friction to decide whether $f_{s,max}$ or T is greater.



Calculate the maximum static friction force:

$$f_{s,max} = \mu_s F_n = \mu_s w = (0.8)(20\text{ N}) = 16\text{ N}$$

(*a*) Because $f_{s,max} > T$:

$$f = f_s = T = \boxed{15.0\text{ N}}$$

(*b*) Because $T > f_{s,max}$:

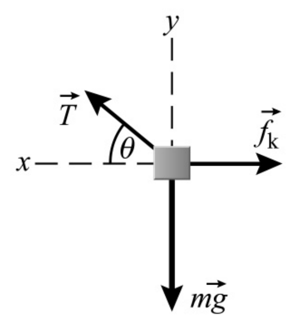
$$f = f_k = \mu_k w = (0.6)(20\text{ N}) = \boxed{12.0\text{ N}}$$

24 •

Picture the Problem The block is in equilibrium under the influence of the forces $\vec{T}$, $\vec{f}_k$, and $m\vec{g}$; i.e.,

$$\vec{T} + \vec{f}_k + m\vec{g} = 0$$

We can apply Newton's 2nd law to determine the relationship between T and f_k.



Apply $\sum F_x = ma_x$ to the block:

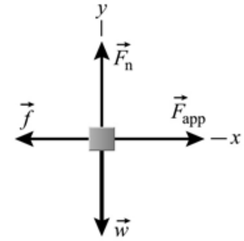
$$T\cos\theta - f_k = ma_x = 0 \text{ because } a_x = 0$$

Solve for f_k:

$$f_k = T\cos\theta \text{ and } \boxed{(b)\text{ is correct.}}$$

25 •

Picture the Problem Whether the friction force is that due to static friction or kinetic friction depends on whether the applied tension is greater than the maximum static friction force.



Calculate the maximum static

$$f_{s,max} = \mu_s F_n = \mu_s w$$

friction force:

$= (0.6)(100\ \text{kg})(9.81\ \text{m/s}^2)$
$= 589\ \text{N}$

Because $f_{s,\max} > F_{app}$, the box does not move and :

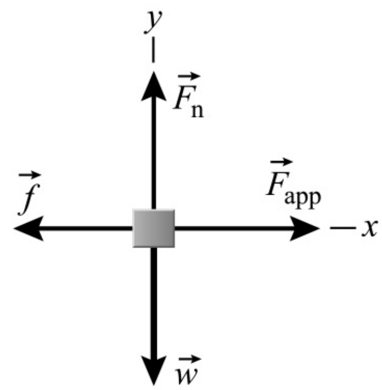
$F_{app} = f_s = \boxed{500\ \text{N}}$

26 •

Picture the Problem Because the box is moving with constant velocity, its acceleration is zero and it is in equilibrium under the influence of $\vec{F}_{app}$, $\vec{F}_n$, $\vec{w}$, and $\vec{f}$; i.e.,

$$\vec{F}_{app} + \vec{F}_n + \vec{w} + \vec{f} = 0$$

We can apply Newton's 2nd law to determine the relationship between f and mg.



The definition of μ_k is:

$$\mu_k = \frac{f_k}{F_n}$$

Apply $\sum F_y = ma_y$ to the box:

$F_n - w = ma_y = 0$ because $a_y = 0$

Solve for F_n:

$F_n = w = 600\ \text{N}$

Apply $\sum F_x = ma_x$ to the box:

$\Sigma F_x = F_{app} - f = ma_x = 0$ because $a_x = 0$

Solve for f_k:

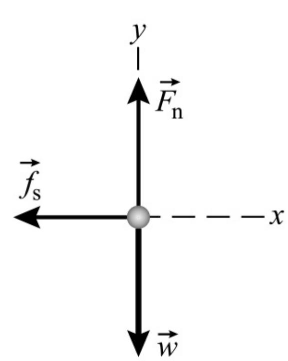
$F_{app} = f_k = 250\ \text{N}$

Substitute to obtain μ_k:

$\mu_k = (250\ \text{N})/(600\ \text{N}) = \boxed{0.417}$

27 •

Picture the Problem Assume that the car is traveling to the right and let the positive x direction also be to the right. We can use Newton's 2nd law of motion and the definition of μ_s to determine the maximum acceleration of the car. Once we know the car's maximum acceleration, we can use a constant-acceleration equation to determine the least stopping distance.



(a) Apply $\sum F_x = ma_x$ to the car: $-f_{s,max} = -\mu_s F_n = ma_x$ (1)

Apply $\sum F_y = ma_y$ to the car and solve for F_n:

$F_n - w = ma_y = 0$

or, because $a_y = 0$,

$F_n = mg$ (2)

Substitute (2) in (1) and solve for $a_{x,max}$:

$$a_{x,max} = \mu_s g = (0.6)(9.81\,\text{m/s}^2) = \boxed{-5.89\,\text{m/s}^2}$$

(b) Using a constant-acceleration equation, relate the stopping distance of the car to its initial velocity and its acceleration and solve for its displacement:

$v^2 = v_0^2 + 2a\Delta x$

or, because $v = 0$,

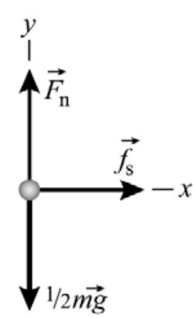
$$\Delta x = \frac{-v_0^2}{2a}$$

Substitute numerical values and evaluate Δx:

$$\Delta x = \frac{-(30\,\text{m/s})^2}{2(-5.89\,\text{m/s}^2)} = \boxed{76.4\,\text{m}}$$

***28** •

Picture the Problem The free-body diagram shows the forces acting on the drive wheels, the ones we're assuming support half the weight of the car. We can use the definition of acceleration and apply Newton's 2nd law to the horizontal and vertical components of the forces to determine the minimum coefficient of friction between the road and the tires.



(a) $\boxed{\text{Because } \mu_s > \mu_k,\ f \text{ will be greater if the wheels do not slip.}}$

(b) Apply $\sum F_x = ma_x$ to the car: $f_s = \mu_s F_n = ma_x$ (1)

Apply $\sum F_y = ma_y$ to the car and solve for F_n:

$F_n - \frac{1}{2}mg = ma_y$

Because $a_y = 0$,

$F_n - \frac{1}{2}mg = 0 \Rightarrow F_n = \frac{1}{2}mg$

Find the acceleration of the car:

$$a_x = \frac{\Delta v}{\Delta t} = \frac{(90\,\text{km/h})(1000\,\text{m/km})}{12\,\text{s}}$$

$$= 2.08\,\text{m/s}^2$$

Solve equation (1) for μ_s:

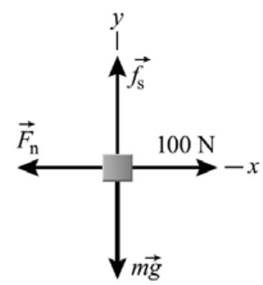
$$\mu_s = \frac{ma_x}{\frac{1}{2}mg} = \frac{2a_x}{g}$$

Substitute numerical values and evaluate a_x:

$$\mu_s = \frac{2(2.08\,\text{m/s}^2)}{9.81\,\text{m/s}^2} = \boxed{0.424}$$

29 •

Picture the Problem The block is in equilibrium under the influence of the forces shown on the free-body diagram. We can use Newton's 2nd law and the definition of μ_s to solve for f_s and F_n.



(*a*) Apply $\sum F_y = ma_y$ to the block and solve for f_s:

$$f_s - mg = ma_y$$

or, because $a_y = 0$,

$$f_s - mg = 0$$

Solve for and evaluate f_s:

$$f_s = mg = (5\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{49.1\,\text{N}}$$

(*b*) Use the definition of μ_s to express F_n:

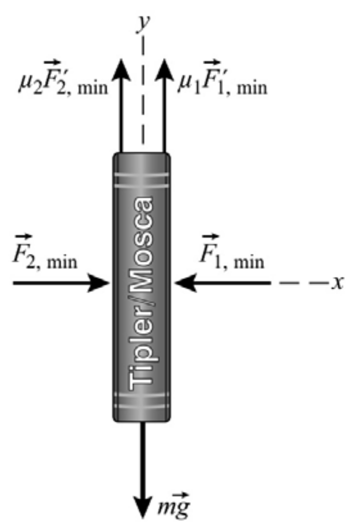
$$F_n = \frac{f_{s,max}}{\mu_s}$$

Substitute numerical values and evaluate F_n:

$$F_n = \frac{49.1\,\text{N}}{0.4} = \boxed{123\,\text{N}}$$

30 •

Picture the Problem The free-body diagram shows the forces acting on the book. The normal force is the net force the student exerts in squeezing the book. Let the horizontal direction be the *x* direction and upward the *y* direction. Note that the normal force is the same on either side of the book because it is not accelerating in the horizontal direction. The book could be accelerating downward. We can apply Newton's 2nd law to relate the minimum force required to hold the book in place to its mass and to the coefficients of static friction. In part (*b*), we can proceed similarly to relate the acceleration of the



book to the coefficients of kinetic friction.

(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the book:

$$\sum F_x = F_{2,\text{min}} - F_{1,\text{min}} = 0$$

and

$$\sum F_y = \mu_{s,1}F'_{1,\text{min}} + \mu_{s,2}F'_{2,\text{min}} - mg = 0$$

Noting that $F'_{1,\text{min}} = F'_{2,\text{min}}$, solve the y equation for F_{min}:

$$F_{\text{min}} = \frac{mg}{\mu_{,1} + \mu_{s,2}}$$

Substitute numerical values and evaluate F_{min}:

$$F_{\text{min}} = \frac{(10.2\,\text{kg})(9.81\,\text{m/s}^2)}{0.32 + 0.16} = \boxed{208\,\text{N}}$$

(*b*) Apply $\sum F_y = ma_y$ with the book accelerating downward, to obtain:

$$\sum F_y = \mu_{k,1}F + \mu_{k,2}F - mg = ma$$

Solve for a to obtain:

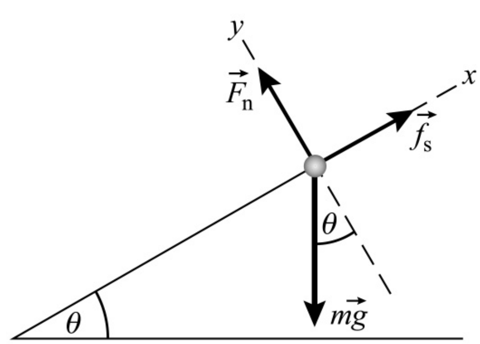
$$a = \frac{\mu_{k,} + \mu_{k,2}}{m}F - g$$

Substitute numerical values and evaluate a:

$$a = \frac{0.2 + 0.09}{10.2\,\text{kg}}(195\,\text{N}) - 9.81\,\text{m/s}^2 = \boxed{-4.27\,\text{m/s}^2}$$

31 •

Picture the Problem A free-body diagram showing the forces acting on the car is shown to the right. The friction force that the ground exerts on the tires is the force f_s shown acting up the incline. We can use the definition of the coefficient of static friction and Newton's 2nd law to relate the angle of the incline to the forces acting on the car.



Apply $\sum \vec{F} = m\vec{a}$ to the car:

$$\sum F_x = f_s - mg\sin\theta = 0 \qquad (1)$$

and

$$\sum F_y = F_n - mg\cos\theta = 0 \qquad (2)$$

Solve equation (1) for f_s and equation (2) for F_n:

$$f_s = mg\sin\theta$$

and

$$F_n = mg\cos\theta$$

Use the definition of μ_s to relate f_s and F_n:

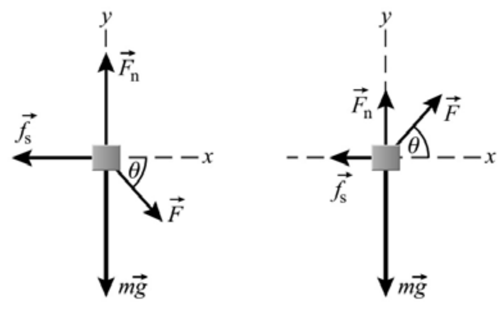
$$\mu_s = \frac{f_s}{F_n} = \frac{mg\sin\theta}{mg\cos\theta} = \tan\theta$$

Solve for and evaluate θ:

$$\theta = \tan^{-1}(\mu_s) = \tan^{-1}(0.08) = \boxed{4.57°}$$

***32** •

Picture the Problem The free-body diagrams for the two methods are shown to the right. Method 1 results in the box being pushed into the floor, increasing the normal force and the static friction force. Method 2 partially lifts the box,, reducing the normal force and the static friction force. We can apply Newton's 2nd law to obtain expressions that relate the maximum static friction force to the applied force $\vec{F}$.



(*a*) $\boxed{\text{Method 2 is preferable as it reduces } F_n \text{ and, therefore, } f_s.}$

(*b*) Apply $\sum F_x = ma_x$ to the box:

$$F\cos\theta - f_s = F\cos\theta - \mu_s F_n = 0$$

Method 1: Apply $\sum F_y = ma_y$ to the block and solve for F_n:

$$F_n - mg - F\sin\theta = 0$$
$$\therefore F_n = mg + F\sin\theta$$

Relate $f_{s,max}$ to F_n:

$$f_{s,max} = \mu_s F_n = \mu_s(mg + F\sin\theta) \qquad (1)$$

Method 2: Apply $\sum F_y = ma_y$ to the forces in the y direction and solve for F_n:

$$F_n - mg + F\sin\theta = 0$$
and
$$F_n = mg - F\sin\theta$$

Relate $f_{s,max}$ to F_n:

$$f_{s,max} = \mu_s F_n = \mu_s(mg - F\sin\theta) \qquad (2)$$

Express the condition that must be satisfied to move the box by either method:

$$f_{s,max} = F\cos\theta \qquad (3)$$

Method 1: Substitute (1) in (3) and solve for F:

$$F_1 = \frac{\mu_s mg}{\cos\theta - \mu_s\sin\theta} \qquad (4)$$

Method 2: Substitute (2) in (3) and solve for F:

$$F_2 = \frac{\mu_s mg}{\cos\theta + \mu_s \sin\theta} \qquad (5)$$

Evaluate equations (4) and (5) with $\theta = 30°$:

$$F_1(30°) = \boxed{520\text{ N}}$$

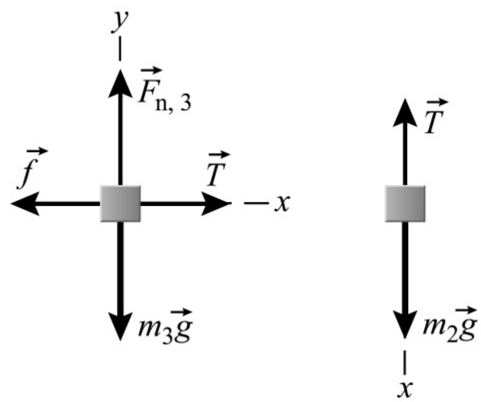
$$F_2(30°) = \boxed{252\text{ N}}$$

Evaluate (4) and (5) with $\theta = 0°$:

$$F_1(0°) = F_2(0°) = \mu_s mg = \boxed{294\text{ N}}$$

33 •

Picture the Problem Draw a free-body diagram for each object. In the absence of friction, the 3-kg box will move to the right, and the 2-kg box will move down. The friction force is indicated by $\vec{f}$ without subscript; it is $\vec{f}_s$ for (*a*) and $\vec{f}_k$ for (*b*). For values of μ_s less than the value found in part (a) required for equilibrium, the system will accelerate and the fall time for a given distance can be found using a constant-acceleration equation.



(*a*) Apply $\sum F_x = ma_x$ to the 3-kg box:

$$T - f_s = 0 \text{ because } a_x = 0 \qquad (1)$$

Apply $\sum F_y = ma_y$ to the 3-kg box, solve for $F_{n,3}$, and substitute in (1):

$$F_{n,3} - m_3 g = 0 \text{ because } a_y = 0$$

and

$$T - \mu_s m_3 g = 0 \qquad (2)$$

Apply $\sum F_x = ma_x$ to the 2-kg box:

$$m_2 g - T = 0 \text{ because } a_x = 0 \qquad (3)$$

Solve (2) and (3) simultaneously and solve for μ_s:

$$\mu_s = \frac{m_2}{m_3} = \boxed{0.667}$$

(*b*) The time of fall is related to the acceleration, which is constant:

$$\Delta x = v_0 \Delta t + \tfrac{1}{2} a (\Delta t)^2$$

or, because $v_0 = 0$,

$$\Delta x = \tfrac{1}{2} a (\Delta t)^2$$

Solve for Δt:

$$\Delta t = \sqrt{\frac{2\Delta x}{a}} \qquad (4)$$

Apply $\sum F_x = ma_x$ to each box:

$$T - \mu_k m_3 g = m_3 a \quad (5)$$

and

$$m_2 g - T = m_2 a \quad (6)$$

Add equations (5) and (6) and solve for a:

$$a = \frac{(m_2 - \mu_k m_3)g}{m_2 + m_3}$$

Substitute numerical values and evaluate a:

$$a = \frac{[2\,\text{kg} - 0.3(3\,\text{kg})](9.81\,\text{m/s}^2)}{2\,\text{kg} + 3\,\text{kg}} = \boxed{2.16\,\text{m/s}^2}$$

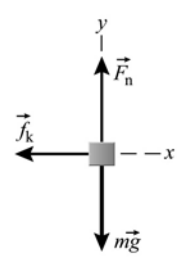
Substitute numerical values in equation (4) and evaluate Δt:

$$\Delta t = \sqrt{\frac{2(2\,\text{m})}{2.16\,\text{m/s}^2}} = \boxed{1.36\,\text{s}}$$

34 ••

Picture the Problem The application of Newton's 2nd law to the block will allow us to express the coefficient of kinetic friction in terms of the acceleration of the block. We can then use a constant-acceleration equation to determine the block's acceleration. The pictorial representation summarizes what we know about the motion.

A free-body diagram showing the forces acting on the block is shown to the right.



Apply $\sum F_x = ma_x$ to the block:

$$-f_k = -\mu_k F_n = ma \quad (1)$$

Apply $\sum F_y = ma_y$ to the block and solve for F_n:

$F_n - mg = 0$ because $a_y = 0$

and

$$F_n = mg \quad (2)$$

Substitute (2) in (1) and solve for μ_k: $\mu_k = -a/g$ (3)

Using a constant-acceleration equation, relate the initial and final velocities of the block to its displacement and acceleration:

$$v_1^2 = v_0^2 + 2a\Delta x$$

or, because $v_1 = 0$, $v_0 = v$, and $\Delta x = d$,

$$0 = v^2 + 2ad$$

Solve for a to obtain:

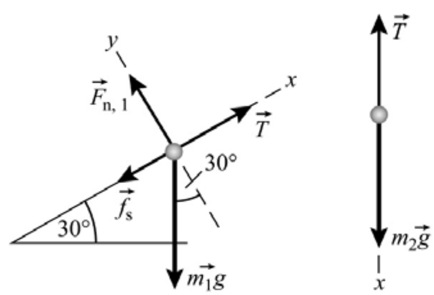
$$a = \frac{-v^2}{2d}$$

Substitute for a in equation (3) to obtain:

$$\mu_k = \boxed{\frac{v^2}{2gd}}$$

***35** ••

Picture the Problem We can find the speed of the system when it has moved a given distance by using a constant-acceleration equation. Under the influence of the forces shown in the free-body diagrams, the blocks will have a common acceleration a. The application of Newton's 2nd law to each block, followed by the elimination of the tension T and the use of the definition of f_k, will allow us to determine the acceleration of the system.



Using a constant-acceleration equation, relate the speed of the system to its acceleration and displacement; solve for its speed:

$$v^2 = v_0^2 + 2a\Delta x$$

and, because $v_0 = 0$,

$$v = \sqrt{2a\Delta x} \qquad (1)$$

Apply $\vec{F}_{net} = m\vec{a}$ to the block whose mass is m_1:

$$\Sigma F_x = T - f_k - m_1 g\sin 30° = m_1 a \qquad (2)$$

and

$$\Sigma F_y = F_{n,1} - m_1 g\cos 30° = 0 \qquad (3)$$

Using $f_k = \mu_k F_n$, substitute (3) in (2) to obtain:

$$T - \mu_k m_1 g\cos 30° - m_1 g\sin 30° = m_1 a$$

Apply $\sum F_x = ma_x$ to the block whose mass is m_2:

$$m_2 g - T = m_2 a$$

Add the last two equations to eliminate T and solve for a to

$$a = \frac{(m_2 - \mu_k m_1\cos 30° - m_1\sin 30°)g}{m_1 + m_2}$$

obtain:

Substitute numerical values and evaluate a:

$$a = 1.16\,\text{m/s}^2$$

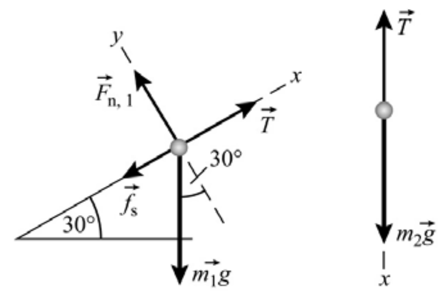
Substitute numerical values in equation (1) and evaluate v:

$$v = \sqrt{2(1.16\,\text{m/s}^2)(0.3\,\text{m})} = 0.835\,\text{m/s}$$

and $\boxed{(a)\text{ is correct.}}$

36 ••

Picture the Problem Under the influence of the forces shown in the free-body diagrams, the blocks are in static equilibrium. While f_s can be either up or down the incline, the free-body diagram shows the situation in which motion is impending up the incline. The application of Newton's 2nd law to each block, followed by the elimination of the tension T and the use of the definition of f_s, will allow us to determine the range of values for m_2.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the block whose mass is m_1:

$$\Sigma F_x = T \pm f_{s,max} - m_1 g\sin 30° = 0 \quad (1)$$

and

$$\Sigma F_y = F_{n,1} - m_1 g\cos 30° = 0 \quad (2)$$

Using $f_{s,max} = \mu_s F_n$, substitute (2) in (1) to obtain:

$$T \pm \mu_s m_1 g\cos 30° - m_1 g\sin 30° = m_1 a \quad (3)$$

Apply $\sum F_x = ma_x$ to the block whose mass is m_2:

$$m_2 g - T = 0 \quad (4)$$

Add equations (3) and (4) to eliminate T and solve for m_2:

$$m_2 = m_1(\pm \mu_s \cos 30° + \sin 30°) = (4\,\text{kg})[\pm(0.4)\cos 30° + \sin 30°] \quad (5)$$

Evaluate (5) denoting the value of m_2 with the plus sign as $m_{2,+}$ and the value of m_2 with the minus sign as $m_{2,-}$ to determine the range of values of m_2 for which the system is in static equilibrium:

$$m_{2,+} = 3.39\,\text{kg and m}_{2,-} = 0.614\,\text{kg}$$

$$\therefore \boxed{0.614\,\text{kg} \le m_2 \le 3.39\,\text{kg}}$$

(b) With $m_2 = 1$ kg, the impending motion is down the incline and the static friction force is up the incline. Apply $\sum F_x = ma_x$ to the block whose mass is m_1:

$$T + f_s - m_1 g\sin 30° = 0 \quad (6)$$

Apply $\sum F_x = ma_x$ to the block whose mass is m_2:

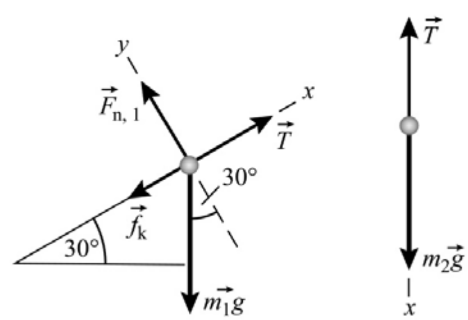
$$m_2 g - T = 0 \quad (7)$$

Add equations (6) and (7) and solve for and evaluate f_s:

$$f_s = (m_1 \sin 30° - m_2)g$$
$$= [(4\text{ kg})\sin 30° - 1\text{ kg}](9.81\text{ m/s}^2)$$
$$= \boxed{9.81\text{N}}$$

37 ••

Picture the Problem Under the influence of the forces shown in the free-body diagrams, the blocks will have a common acceleration a. The application of Newton's 2nd law to each block, followed by the elimination of the tension T and the use of the definition of f_k, will allow us to determine the acceleration of the system. Finally, we can substitute for the tension in either of the motion equations to determine the acceleration of the masses.



Apply $\sum \vec{F} = m\vec{a}$ to the block whose mass is m_1:

$$\Sigma F_x = T - f_k - m_1 g\sin 30° = m_1 a \quad (1)$$

and

$$\Sigma F_y = F_{n,1} - m_1 g\cos 30° = 0 \quad (2)$$

Using $f_k = \mu_k F_n$, substitute (2) in (1) to obtain:

$$T - \mu_k m_1 g\cos 30° - m_1 g\sin 30° = m_1 a \quad (3)$$

Apply $\sum F_x = ma_x$ to the block whose mass is m_2:

$$m_2 g - T = m_2 a \quad (4)$$

Add equations (3) and (4) to eliminate T and solve for a to obtain:

$$a = \frac{(m_2 - \mu_k m_1 \cos 30° - m_1 \sin 30°)g}{m_1 + m_2}$$

Substituting numerical values and evaluating a yields:

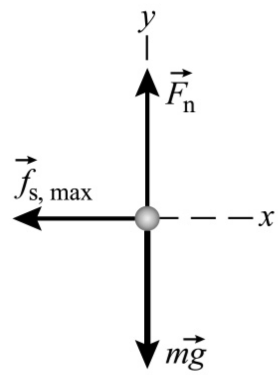
$$a = \boxed{2.36\text{ m/s}^2}$$

Substitute for a in equation (3) to obtain:

$$T = \boxed{37.3\,\text{N}}$$

***38 ••**

Picture the Problem The truck will stop in the shortest possible distance when its acceleration is a maximum. The maximum acceleration is, in turn, determined by the maximum value of the static friction force. The free-body diagram shows the forces acting on the box as the truck brakes to a stop. Assume that the truck is moving in the positive x direction and apply Newton's 2nd law and the definition of $f_{s,max}$ to find the shortest stopping distance.



Using a constant-acceleration equation, relate the truck's stopping distance to its acceleration and initial velocity; solve for the stopping distance:

$$v^2 = v_0^2 + 2a\Delta x$$

or, since $v = 0$,

$$\Delta x_{min} = \sqrt{\frac{-v_0^2}{2a_{max}}}$$

Apply $\vec{F}_{net} = m\vec{a}$ to the block:

$$\Sigma F_x = -f_{s,max} = ma_{max} \qquad (1)$$

and

$$\Sigma F_y = F_n - mg = 0 \qquad (2)$$

Using the definition of $f_{s,max}$, solve equations (1) and (2) simultaneously for a:

$$f_{s,max} \equiv \mu_s F_n$$

and

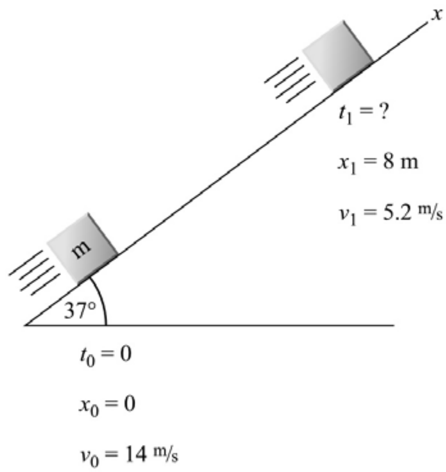
$$a_{max} = -\mu_s g = -(0.3)(9.81\text{ m/s}^2) = -2.943\text{ m/s}^2$$

Substitute numerical values and evaluate Δx_{min}:

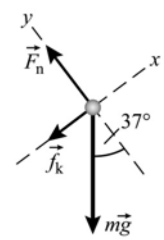
$$\Delta x_{min} = \sqrt{\frac{-(80\,\text{km/h})^2(1000\,\text{km/m})^2(1\,\text{h}/3600\,\text{s})^2}{2(-2.943\,\text{m/s}^2)}} = \boxed{9.16\,\text{m}}$$

39 ••

Picture the Problem We can find the coefficient of friction by applying Newton's 2nd law and determining the acceleration from the given values of displacement and initial velocity. We can find the displacement and speed of the block by using constant-acceleration equations. During its motion up the incline, the sum of the kinetic friction force and a component of the object's weight will combine to bring the object to rest. When it is moving down the incline, the difference between the weight component and the friction force will be the net force.



(*a*) Draw a free-body diagram for the block as it travels up the incline:



Apply $\sum \vec{F} = m\vec{a}$ to the block:

$$\Sigma F_x = -f_k - mg\sin 37° = ma \qquad (1)$$

and

$$\Sigma F_y = F_n - mg\cos 37° = 0 \qquad (2)$$

Substitute $f_k = \mu_k F_n$ and F_n from (2) in (1) and solve for μ_k:

$$\mu_k = \frac{-g\sin 37° - a}{g\cos 37°} = -\tan 37° - \frac{a}{g\cos 37°} \qquad (3)$$

Using a constant-acceleration equation, relate the final velocity of the block to its initial velocity, acceleration, and displacement:

$$v_1^2 = v_0^2 + 2a\Delta x$$

Solving for a yields:

$$a = \frac{v_1^2 - v_0^2}{2\Delta x}$$

Substitute numerical values and evaluate a:

$$a = \frac{(5.2\,\text{m/s})^2 - (14\,\text{m/s})^2}{2(8\,\text{m})} = -10.6\,\text{m/s}^2$$

Substitute for a in (3) to obtain:

$$\mu_k = -\tan 37° - \frac{-10.6\,\text{m/s}^2}{(9.81\,\text{m/s}^2)\cos 37°} = \boxed{0.599}$$

(b) Use the same constant-acceleration equation used above but with $v_1 = 0$ to obtain:

$$0 = v_0^2 + 2a\Delta x$$

Solve for Δx to obtain:

$$\Delta x = \frac{-v_0^2}{2a}$$

Substitute numerical values and evaluate Δx:

$$\Delta x = \frac{-(14\,\text{m/s})^2}{2(-10.6\,\text{m/s}^2)} = \boxed{9.25\,\text{m}}$$

(c) When the block slides down the incline, f_k is in the positive x direction:

$$\Sigma F_x = f_k - mg\sin 37° = ma$$

and

$$\Sigma F_y = F_n - mg\cos 37° = 0$$

Solve for a as in part (a):

$$a = g(\mu_k \cos 37° - \sin 37°) = -1.21\,\text{m/s}^2$$

Use the same constant-acceleration equation used in part (b) to obtain:

$$v^2 = v_0^2 + 2a\Delta x$$

Set $v_0 = 0$ and solve for v:

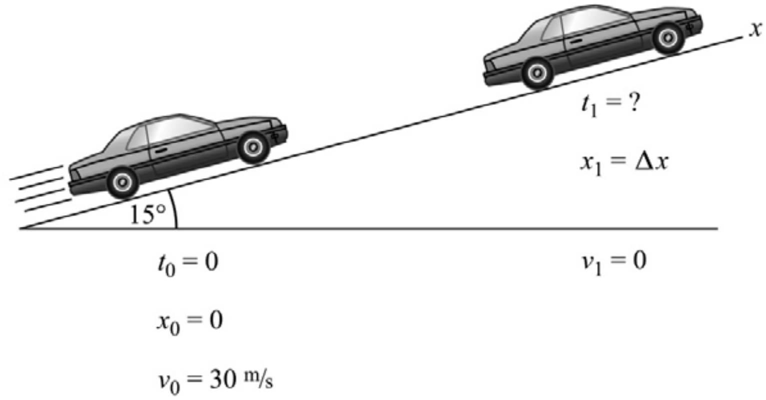
$$v = \sqrt{2a\Delta x}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{2(-1.21\,\text{m/s}^2)(-9.25\,\text{m})} = \boxed{4.73\,\text{m/s}}$$

40 ••

Picture the Problem We can find the stopping distances by applying Newton's 2nd law to the automobile and then using a constant-acceleration equation. The friction force the road exerts on the tires and the component of the car's weight along the incline combine to provide the net force that stops the car. The pictorial representation summarizes what we know about the motion of the car. We can use Newton's 2nd law to determine the acceleration of the car and a constant-acceleration equation to obtain its stopping distance.



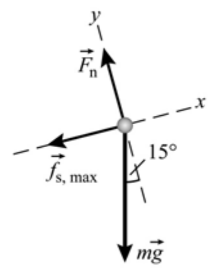
(*a*) Using a constant-acceleration equation, relate the final speed of the car to its initial speed, acceleration, and displacement; solve for its displacement:

$$v_1^2 = v_0^2 + 2a_{\max}\Delta x_{\min}$$

or, because $v_1 = 0$,

$$\Delta x_{\min} = \frac{-v_0^2}{2a_{\max}}$$

Draw the free-body diagram for the car going up the incline:



Apply $\sum \vec{F} = m\vec{a}$ to the car:

$$\Sigma F_x = -f_{s,\max} - mg\sin 15° = ma \quad (1)$$

and

$$\Sigma F_y = F_n - mg\cos 15° = 0 \quad (2)$$

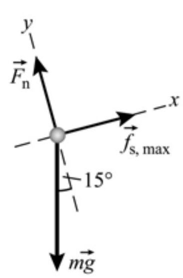
Substitute $f_{s,\max} = \mu_s F_n$ and F_n from (2) in (1) and solve for a:

$$a_{\max} = -g\left(\mu_s \cos 15° + \sin 15°\right) = -9.17\ \text{m/s}^2$$

Substitute numerical values in the expression for $\Delta x_{\min}$ to obtain:

$$\Delta x_{\min} = \frac{-(30\ \text{m/s})^2}{2\left(-9.17\ \text{m/s}^2\right)} = \boxed{49.1\ \text{m}}$$

(*b*) Draw the free-body diagram for the car going down the incline:



Apply $\sum \vec{F} = m\vec{a}$ to the car:

$$\Sigma F_x = f_{s,max} - mg\sin 15° = ma$$
and
$$\Sigma F_y = F_n - mg\cos 15° = 0$$

Proceed as in (*a*) to obtain a_{max}:

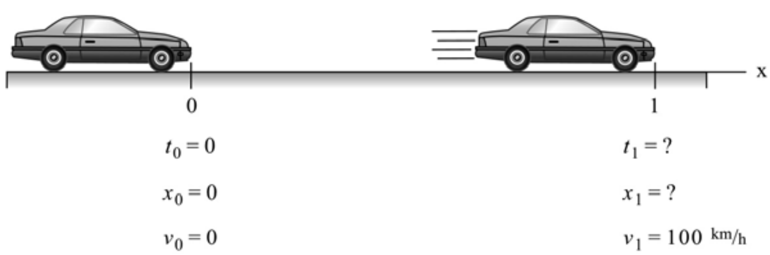
$$a_{max} = g(\mu_s \cos 15° - \sin 15°) = 4.09\,\text{m/s}^2$$

Again, proceed as in (*a*) to obtain the displacement of the car:

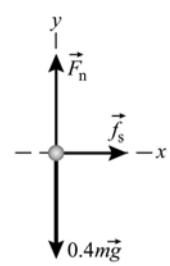
$$\Delta x_{min} = \left|\frac{-v_0^2}{2a_{max}}\right| = \frac{(30\,\text{m/s})^2}{2(4.09\,\text{m/s}^2)} = \boxed{110\,\text{m}}$$

41 ••

Picture the Problem The friction force the road exerts on the tires provides the net force that accelerates the car. The pictorial representation summarizes what we know about the motion of the car. We can use Newton's 2nd law to determine the acceleration of the car and a constant-acceleration equation to calculate how long it takes it to reach 100 km/h.



(*a*) Because 40% of the car's weight is on its two drive wheels and the accelerating friction forces act just on these wheels, the free-body diagram shows just the forces acting on the drive wheels.



Apply $\sum \vec{F} = m\vec{a}$ to the car:

$$\Sigma F_x = f_{s,max} = ma \qquad (1)$$
and
$$\Sigma F_y = F_n - 0.4mg = 0 \qquad (2)$$

Use the definition of $f_{s,max}$ in equation (1) and eliminate F_n between the two equations to obtain:

$$a = 0.4\mu_s g = 0.4(0.7)(9.81\,\text{m/s}^2) = \boxed{2.75\,\text{m/s}^2}$$

(*b*) Using a constant-acceleration equation, relate the initial and final

$$v_1 = v_0 + a\Delta t$$

velocities of the car to its acceleration and the elapsed time; solve for the time:

or, because $v_0 = 0$ and $\Delta t = t_1$,

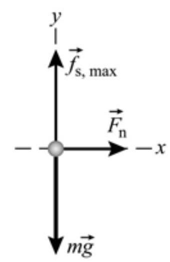
$$t_1 = \frac{v_1}{a}$$

Substitute numerical values and evaluate t_1:

$$t_1 = \frac{(100\,\text{km/h})(1\,\text{h}/3600\,\text{s})(1000\,\text{m/km})}{2.75\,\text{m/s}^2} = \boxed{10.1\,\text{s}}$$

***42 ••**

Picture the Problem To hold the box in place, the acceleration of the cart and box must be great enough so that the static friction force acting on the box will equal the weight of the box. We can use Newton's 2nd law to determine the minimum acceleration required.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the box:

$$\Sigma F_x = F_n = ma_{min} \quad (1)$$

and

$$\Sigma F_y = f_{s,max} - mg = 0 \quad (2)$$

Substitute μF_n for $f_{s,max}$ in equation (2), eliminate F_n between the two equations and solve for and evaluate a_{min}:

$$\mu F_n - mg = 0, \quad \mu(ma_{min}) - mg = 0$$

and

$$a_{min} = \frac{g}{\mu_s} = \frac{9.81\,\text{m/s}^2}{0.6} = \boxed{16.4\,\text{m/s}^2}$$

(*b*) Solve equation (2) for $f_{s,max}$, and substitute numerical values and evaluate $f_{s,max}$:

$$f_{s,max} = mg = (2\text{ kg})(9.81\text{ m/s}^2) = \boxed{19.6\,\text{N}}$$

(*c*) If a is twice that required to hold the box in place, f_s will still have its maximum value given by:

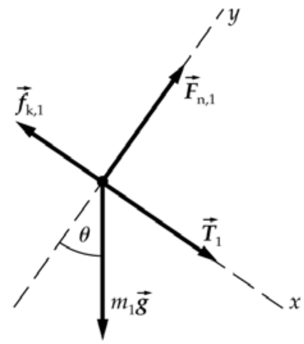
$$f_{s,max} = \boxed{19.6\,\text{N}}$$

(*d*) $\boxed{\text{Because } g/\mu_s \text{ is } a_{min}\text{, the box will not fall if } a \geq g/\mu_s.}$

43 ••

Picture the Problem Note that the blocks have a common acceleration and that the tension in the string acts on both blocks in accordance with Newton's third law of motion. Let down the incline be the positive *x* direction. Draw the free-body diagrams for each block and apply Newton's second law of motion and the definition of the kinetic friction force to each block to obtain simultaneous equations in a_x and T.

Draw the free-body diagram for the block whose mass is m_1:



Apply $\sum \vec{F} = m\vec{a}$ to the upper block:

$$\Sigma F_x = -f_{k,1} + T_1 + m_1 g\sin\theta = m_1 a_x \quad (1)$$

and

$$\Sigma F_y = F_{n,1} - m_1 g\cos\theta = 0 \quad (2)$$

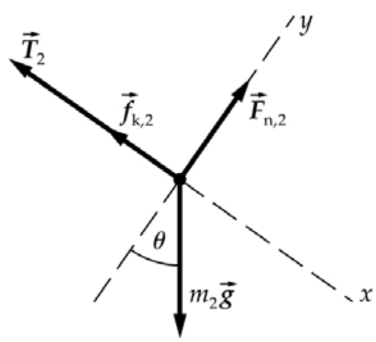
The relationship between $f_{k,1}$ and $F_{n,1}$ is:

$$f_{k,1} = \mu_{k,1} F_{n,1} \quad (3)$$

Eliminate $f_{k,1}$ and $F_{n,1}$ between (1), (2), and (3) to obtain:

$$-\mu_{k,1} m_1 g\cos\theta + T_1 + m_1 g\sin\theta = m_1 a_x \quad (4)$$

Draw the free-body diagram for the block whose mass is m_2:



Apply $\sum \vec{F} = m\vec{a}$ to the block:

$$\Sigma F_x = -f_{k,2} - T_2 + m_2 g\sin\theta = m_2 a_x \quad (5)$$

and

$$\Sigma F_y = F_{n,2} - m_2 g\cos\theta = 0 \quad (6)$$

The relationship between $f_{k,2}$ and $F_{n,2}$ is:

$$f_{k,2} = \mu_{k,2} F_{n,2} \quad (7)$$

Eliminate $f_{k,2}$ and $F_{n,2}$ between (5), (6), and (7) to obtain:

$$-\mu_{k,2} m_2 g\cos\theta - T_2 + m_2 g\sin\theta = m_2 a_x \quad (8)$$

Noting that $T_2 = T_1 = T$, add equations (4) and (8) to eliminate T and solve for a_x:

$$a_x = \left[\sin\theta - \frac{\mu_{k,1}m_1 + \mu_{k,2}m_2}{m_1 + m_2}\cos\theta\right]g$$

Substitute numerical values and evaluate a_x to obtain:

$$a_x = \boxed{-0.965\,\text{m/s}^2}$$ where the minus sign tells us that the acceleration is directed up the incline.

(*b*) Eliminate a_x between equations (4) and (8) and solve for $T = T_1 = T_2$ to obtain:

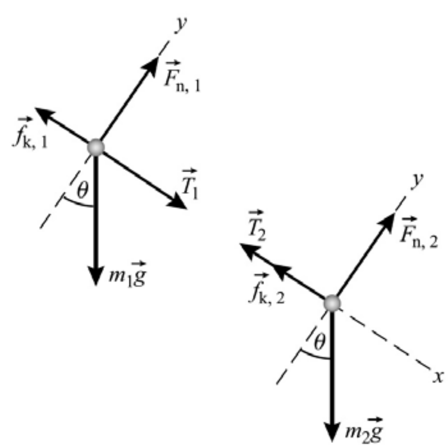
$$T = \frac{m_1 m_2(\mu_{k,2} - \mu_{k,1})g\cos\theta}{m_1 + m_2}$$

Substitute numerical values and evaluate T:

$$T = \boxed{0.184\,\text{N}}$$

***44** ••

Picture the Problem The free-body diagram shows the forces acting on the two blocks as they slide down the incline. Down the incline has been chosen as the positive x direction. T is the force transmitted by the stick; it can be either tensile ($T > 0$) or compressive ($T < 0$). By applying Newton's 2nd law to these blocks, we can obtain equations in T and a from which we can eliminate either by solving them simultaneously. Once we have expressed T, the role of the stick will become apparent.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to block 1:

$$\sum F_x = T_1 + m_1 g\sin\theta - f_{k,1} = m_1 a$$

and

$$\sum F_y = F_{n,1} - m_1 g\cos\theta = 0$$

Apply $\sum \vec{F} = m\vec{a}$ to block 2:

$$\sum F_x = m_2 g\sin\theta - T_2 - f_{k,2} = m_2 a$$

and

$$\sum F_y = F_{n,2} - m_2 g\cos\theta = 0$$

Letting $T_1 = T_2 = T$, use the definition of the kinetic friction force to eliminate $f_{k,1}$ and $F_{n,1}$ between the equations for block 1 and $f_{k,2}$ and $F_{n,1}$ between the equations for block 2 to obtain:

$$m_1 a = m_1 g\sin\theta + T - \mu_1 m_1 g\cos\theta \qquad (1)$$

and

$$m_2 a = m_2 g\sin\theta - T - \mu_2 m_2 g\cos\theta \qquad (2)$$

Add equations (1) and (2) to eliminate T and solve for a:

$$\boxed{a = g\left(\sin\theta - \frac{\mu_1 m_1 + \mu_2 m_2}{m_1 + m_2}\cos\theta\right)}$$

(*b*) Rewrite equations (1) and (2) by dividing both sides of (1) by m_1 and both sides of (2) by m_2 to obtain.

$$a = g\sin\theta + \frac{T}{m_1} - \mu_1 g\cos\theta \qquad (3)$$

and

$$a = g\sin\theta - \frac{T}{m_2} - \mu_2 g\cos\theta \qquad (4)$$

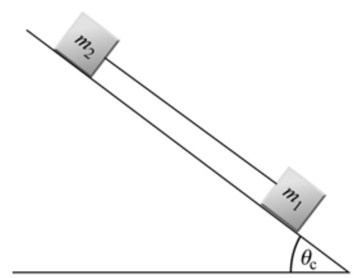
Subtracting (4) from (3) and rearranging yields:

$$\boxed{T = \left(\frac{m_1 m_2}{m_1 - m_2}\right)(\mu_1 - \mu_2)g\cos\theta}$$

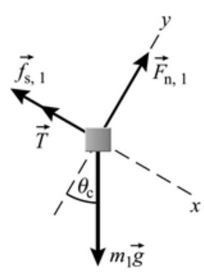
If $\mu_1 = \mu_2, T = 0$ and the blocks move down the incline with the same acceleration of $g(\sin\theta - \mu\cos\theta)$. Inserting a stick between them can't change this; therefore, the stick must exert no force on either block.

45 ••

Picture the Problem The pictorial representation shows the orientation of the two blocks on the inclined surface. Draw the free-body diagrams for each block and apply Newton's 2nd law of motion and the definition of the static friction force to each block to obtain simultaneous equations in θ_c and T.



(*a*) Draw the free-body diagram for the lower block:



Apply $\sum\vec{F} = m\vec{a}$ to the block:

$$\Sigma F_x = m_1 g\sin\theta_c - f_{s,1} - T = 0 \qquad (1)$$

and

$$\Sigma F_y = F_{n,1} - m_1 g\cos\theta_c = 0 \qquad (2)$$

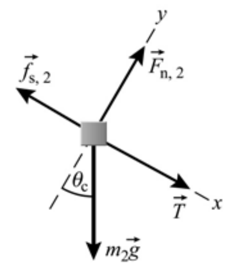
The relationship between $f_{s,1}$ and $F_{n,1}$ is:

$$f_{s,1} = \mu_{s,1}F_{n,1} \qquad (3)$$

Eliminate $f_{s,1}$ and $F_{n,1}$ between (1), (2), and (3) to obtain:

$$m_1 g\sin\theta_c - \mu_{s,1} m_1 g\cos\theta_c - T = 0 \quad (4)$$

Draw the free-body diagram for the upper block:



Apply $\sum \vec{F} = m\vec{a}$ to the block:

$$\Sigma F_x = T + m_2 g\sin\theta_c - f_{s,2} = 0 \quad (5)$$

and

$$\Sigma F_y = F_{n,2} - m_2 g\cos\theta_c = 0 \quad (6)$$

The relationship between $f_{s,2}$ and $F_{n,2}$ is:

$$f_{s,2} = \mu_{s,2} F_{n,2} \quad (7)$$

Eliminate $f_{s,2}$ and $F_{n,2}$ between (5), (6), and (7) to obtain:

$$T + m_2 g\sin\theta_c - \mu_{s,2} m_2 g\cos\theta_c = 0 \quad (8)$$

Add equations (4) and (8) to eliminate T and solve for θ_c:

$$\theta_c = \tan^{-1}\left[\frac{\mu_{s,1}m_1 + \mu_{s,2}m_2}{m_1 + m_2}\right] = \tan^{-1}\left[\frac{(0.4)(0.2\,\text{kg}) + (0.6)(0.1\,\text{kg})}{0.1\,\text{kg} + 0.2\,\text{kg}}\right] = \boxed{25.0°}$$

(*b*) Because θ_c is greater than the angle of repose ($\tan^{-1}(\mu_{s,1}) = \tan^{-1}(0.4) = 21.8°$) for the lower block, it would slide if $T = 0$. Solve equation (4) for T:

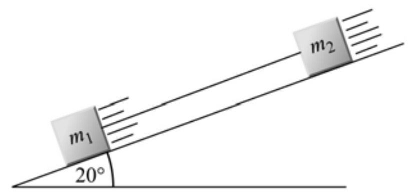
$$T = m_1 g(\sin\theta_C - \mu_{s,1}\cos\theta_C)$$

Substitute numerical values and evaluate T:

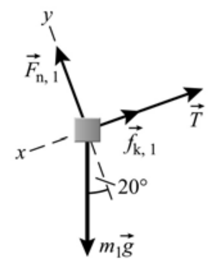
$$T = (0.2\,\text{kg})(9.81\,\text{m/s}^2)[\sin 25° - (0.4)\cos 25°] = \boxed{0.118\,\text{N}}$$

46 ••

Picture the Problem The pictorial representation shows the orientation of the two blocks with a common acceleration on the inclined surface. Draw the free-body diagrams for each block and apply Newton's 2nd law and the definition of the kinetic friction force to each block to obtain simultaneous equations in a and T.



(a) Draw the free-body diagram for the lower block:



Apply $\sum \vec{F} = m\vec{a}$ to the lower block:

$$\Sigma F_x = m_1 g\sin 20° - f_{k,1} - T = m_1 a \quad (1)$$

and

$$\Sigma F_y = F_{n,1} - m_1 g\cos 20° = 0 \quad (2)$$

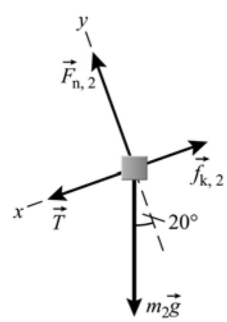
Express the relationship between $f_{k,1}$ and $F_{n,1}$:

$$f_{k,1} = \mu_{k,1} F_{n,1} \quad (3)$$

Eliminate $f_{k,1}$ and $F_{n,1}$ between (1), (2), and (3) to obtain:

$$m_1 g\sin 20° - \mu_{k,1} m_1 g\cos 20° - T = m_1 a \quad (4)$$

Draw the free-body diagram for the upper block:



Apply $\sum \vec{F} = m\vec{a}$ to the upper block:

$$\Sigma F_x = T + m_2 g\sin 20° - f_{k,2} = m_2 a \quad (5)$$

and

$$\Sigma F_y = F_{n,2} - m_2 g\cos 20° = 0 \quad (6)$$

Express the relationship between $f_{k,2}$ and $F_{n,2}$:

$$f_{k,2} = \mu_{k,2} F_{n,2} \quad (7)$$

Eliminate $f_{k,2}$ and $F_{n,2}$ between (5), (2), and (7) to obtain:

$$T + m_2 g \sin 20° - \mu_{k,2} m_2 g \cos 20° = m_2 a \quad (8)$$

Add equations (4) and (8) to eliminate T and solve for a:

$$a = \boxed{g\left(\sin 20° - \frac{\mu_1 m_1 + \mu_2 m_2}{m_1 + m_2}\cos 20°\right)}$$

Substitute the given values and evaluate a:

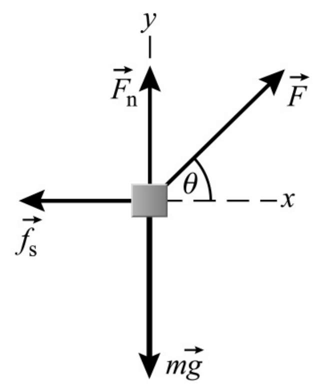
$$a = \boxed{0.944\,\text{m/s}^2}$$

(*b*) Substitute for a in either equation (4) or equation (8) to obtain:

$T = \boxed{-0.426\,\text{N}}$; i.e., the rod is under compression.

***47 ••**

Picture the Problem The vertical component of $\vec{F}$ reduces the normal force; hence, the static friction force between the surface and the block. The horizontal component is responsible for any tendency to move and equals the static friction force until it exceeds its maximum value. We can apply Newton's 2nd law to the box, under equilibrium conditions, to relate F to θ.



(*a*) The static-frictional force opposes the motion of the object, and the maximum value of the static-frictional force is proportional to the normal force F_N. The normal force is equal to the weight minus the vertical component F_V of the force F. Keeping the magnitude F constant while increasing θ from zero results in a decrease in F_V and thus a corresponding decrease in the maximum static-frictional force f_{max}. The object will begin to move if the horizontal component F_H of the force F exceeds f_{max}. An increase in θ results in a decrease in F_H. As θ increases from 0, the decrease in F_N is larger than the decrease in F_H, so the object is more and more likely to slip. However, as θ approaches 90°, F_H approaches zero and no movement will be initiated. If F is large enough and if θ increases from 0, then at some value of θ the block will start to move.

(*b*) Apply $\sum \vec{F} = m\vec{a}$ to the block:

$$\Sigma F_x = F\cos\theta - f_s = 0 \quad (1)$$

and

$$\Sigma F_y = F_n + F\sin\theta - mg = 0 \quad (2)$$

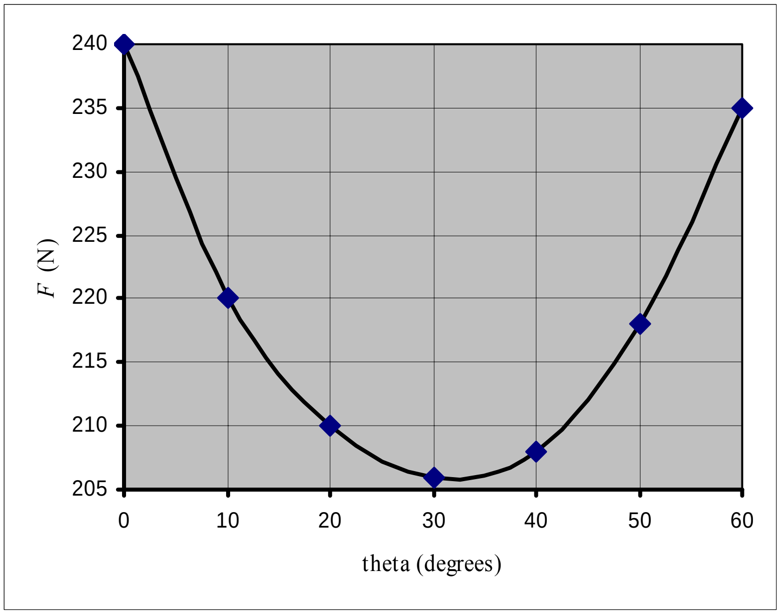
Assuming that $f_s = f_{s,max}$, eliminate f_s and F_n between equations (1) and (2) and solve for F:

$$F = \frac{\mu_s mg}{\cos\theta + \mu_s \sin\theta}$$

Use this function with $mg = 240$ N to generate the table shown below:

θ	(deg)	0	10	20	30	40	50	60
F	(N)	240	220	210	206	208	218	235

The following graph of $F(\theta)$ was plotted using a spreadsheet program.

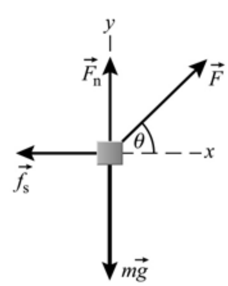


From the graph, we can see that the minimum value for F occurs when $\theta \approx 32°$.

Remarks: An alternative to manually plotting F as a function of θ or using a spreadsheet program is to use a graphing calculator to enter and graph the function.

48 •••

Picture the Problem The free-body diagram shows the forces acting on the block. We can apply Newton's 2nd law, under equilibrium conditions, to relate F to θ and then set its derivative with respect to θ equal to zero to find the value of θ that minimizes F.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the block:

$$\Sigma F_x = F\cos\theta - f_s = 0 \quad (1)$$

and

$$\Sigma F_y = F_n + F\sin\theta - mg = 0 \quad (2)$$

Assuming that $f_s = f_{s,max}$, eliminate f_s and F_n between equations (1) and (2) and solve for F:

$$F = \frac{\mu_s mg}{\cos\theta + \mu_s \sin\theta} \quad (3)$$

To find θ_{min}, differentiate F with respect to θ and set the derivative equal to zero for extrema of the function:

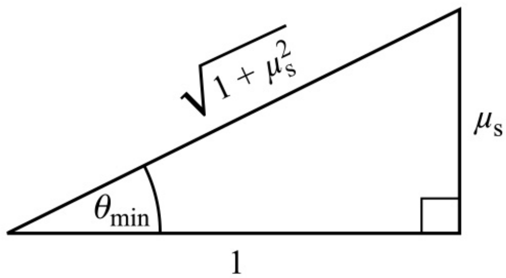
$$\frac{dF}{d\theta} = \frac{(\cos\theta + \mu_s \sin\theta)\frac{d}{d\theta}(\mu_s mg)}{(\cos\theta + \mu_s \sin\theta)^2} - \frac{\mu_s mg \frac{d}{d\theta}(\cos\theta + \mu_s \sin\theta)}{(\cos\theta + \mu_s \sin\theta)^2}$$

$$= \frac{\mu_s mg(-\sin\theta + \mu_s \cos\theta)}{(\cos\theta + \mu_s \sin\theta)^2} = 0 \text{ for extrema}$$

Solve for θ_{min} to obtain:

$$\theta_{min} = \boxed{\tan^{-1}\mu_s}$$

(*b*) Use the reference triangle shown below to substitute for $\cos\theta$ and $\sin\theta$ in equation (3):



$$F_{min} = \frac{\mu_s mg}{\frac{1}{\sqrt{1+\mu_s^2}} + \mu_s \frac{\mu_s}{\sqrt{1+\mu_s^2}}} = \frac{\mu_s mg}{\frac{1+\mu_s^2}{\sqrt{1+\mu_s^2}}} = \boxed{\frac{\mu_s}{\sqrt{1+\mu_s^2}} mg}$$

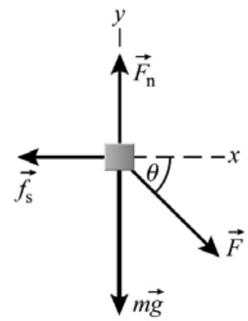
(*c*)

The coefficient of kinetic friction is less than the coefficient of static friction. An analysis identical to the one above shows that the minimum force one should apply to keep the block moving should be applied at an angle given by $\theta_{min} = \tan^{-1}\mu_k$. Therefore, once the block is moving the coefficient of friction will decrease, so the angle can be decreased.

49 ••

Picture the Problem The vertical component of $\vec{F}$ increases the normal force and the static friction force between the surface and the block. The horizontal component is responsible for any tendency to move and equals the static friction force until it exceeds its maximum value. We can apply Newton's 2nd law to the box, under equilibrium conditions, to relate F to θ.

(*a*) As θ increases from zero, F increases the normal force exerted by the surface and the static friction force. As the horizontal component of F decreases with increasing θ, one would expect F to continue to increase.



(*b*) Apply $\sum \vec{F} = m\vec{a}$ to the block:

$$\Sigma F_x = F\cos\theta - f_s = 0 \quad (1)$$

and

$$\Sigma F_y = F_n - F\sin\theta - mg = 0 \quad (2)$$

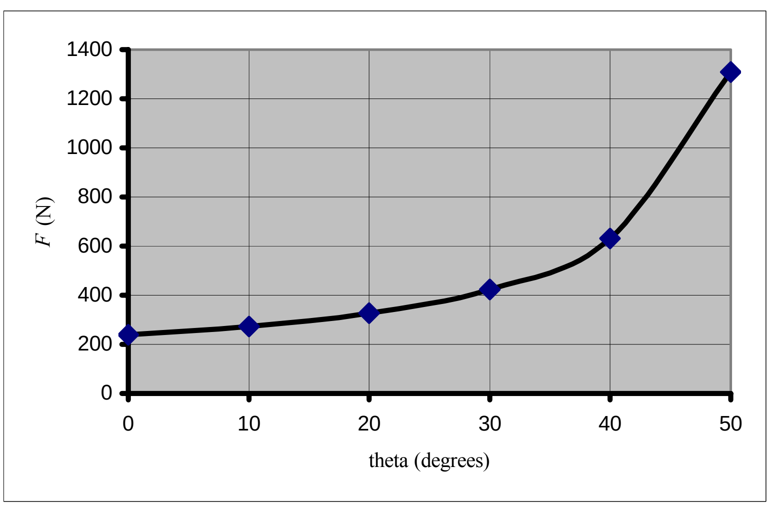
Assuming that $f_s = f_{s,max}$, eliminate f_s and F_n between equations (1) and (2) and solve for F:

$$F = \frac{\mu_s mg}{\cos\theta - \mu_s \sin\theta} \quad (3)$$

Use this function with $mg = 240$ N to generate the table shown below.

θ	(deg)	0	10	20	30	40	50	60
F	(N)	240	273	327	424	631	1310	very large

The graph of F as a function of θ, plotted using a spreadsheet program, confirms our prediction that F continues to increase with θ.



(*a*) From the graph we see that: $\theta_{min} = \boxed{0°}$

(*b*) Evaluate equation (3) for $\theta = 0°$ to obtain:

$$F = \frac{\mu_s mg}{\cos 0° - \mu_s \sin 0°} = \boxed{\mu_s mg}$$

(*c*)

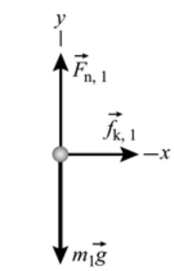
$$\boxed{\text{You should keep the angle at } 0°.}$$

Remarks: An alternative to the use of a spreadsheet program is to use a graphing calculator to enter and graph the function.

50 ••

Picture the Problem The forces acting on each of these masses are shown in the free-body diagrams below. m_1 represents the mass of the 20-kg mass and m_2 that of the 100-kg mass. As described by Newton's 3rd law, the normal reaction force $F_{n,1}$ and the friction force $f_{k,1}$ $(= f_{k,2})$ act on both masses but in opposite directions. Newton's 2nd law and the definition of kinetic friction forces can be used to determine the various forces and the acceleration called for in this problem.

(*a*) Draw a free-body diagram showing the forces acting on the 20-kg mass:



Apply $\sum \vec{F} = m\vec{a}$ to this mass:

$$\Sigma F_x = f_{k,1} = m_1 a_1 \quad (1)$$

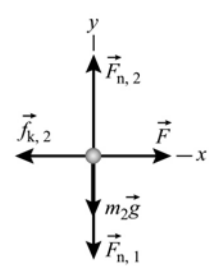
and

$$\Sigma F_y = F_{n,1} - m_1 g = 0 \quad (2)$$

Solve equation (1) for $f_{k,1}$:

$$f_{k,1} = m_1 a_1 = (20\text{ kg})(4\text{ m/s}^2) = \boxed{80.0\text{ N}}$$

(*b*) Draw a free-body diagram showing the forces acting on the 100-kg mass:



Apply $\sum F_x = ma_x$ to the 100-kg object and evaluate F_{net}:

$$F_{net} = m_2 a_2$$
$$= (100\text{ kg})(6\text{ m/s}^2) = \boxed{600\text{ N}}$$

Express F in terms of F_{net} and $f_{k,2}$:

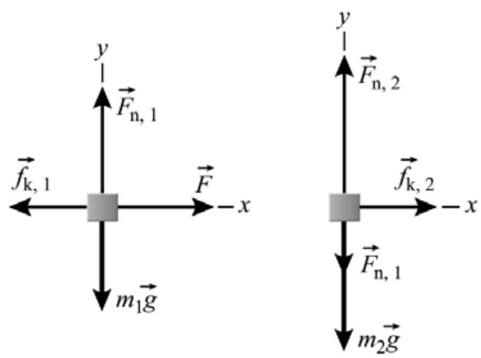
$$F = F_{net} + f_{k,2} = 600\text{ N} + 80\text{ N} = \boxed{680\text{ N}}$$

(c) When the 20-kg mass falls off, the 680-N force acts just on the 100-kg mass and its acceleration is given by Newton's 2nd law:

$$a = \frac{F_{net}}{m} = \frac{680\text{ N}}{100\text{ kg}} = \boxed{6.80\text{ m/s}^2}$$

51 ••

Picture the Problem The forces acting on each of these blocks are shown in the free-body diagrams to the right. m_1 represents the mass of the 60-kg block and m_2 that of the 100-kg block. As described by Newton's 3rd law, the normal reaction force $F_{n,1}$ and the friction force $f_{k,1}$ ($= f_{k,2}$) act on both objects but in opposite directions. Newton's 2nd law and the definition of kinetic friction forces can be used to determine the coefficient of kinetic friction and acceleration of the 100-kg block.



(a) Apply $\sum \vec{F} = m\vec{a}$ to the 60-kg block:

$$\Sigma F_x = F - f_{k,1} = m_1 a_1 \qquad (1)$$

and

$$\Sigma F_y = F_{n,1} - m_1 g = 0 \qquad (2)$$

Apply $\sum F_x = ma_x$ to the 100-kg block:

$$f_{k,2} = m_2 a_2 \qquad (3)$$

Using equation (2), express the relationship between the kinetic friction forces $\vec{f}_{k,1}$ and $\vec{f}_{k,2}$:

$$f_{k,1} = f_{k,2} = f_k = \mu_k F_{n,1} = \mu_k m_1 g \quad (4)$$

Substitute equation (4) into equation (1) and solve for μ_k:

$$\mu_k = \frac{F - m_1 a_1}{m_1 g}$$

Substitute numerical values and evaluate μ_k:

$$\mu_k = \frac{320\text{ N} - (60\text{ kg})(3\text{ m/s}^2)}{(60\text{ kg})(9.81\text{ m/s}^2)} = \boxed{0.238}$$

(b) Substitute equation (4) into equation (3) and solve for a_2:

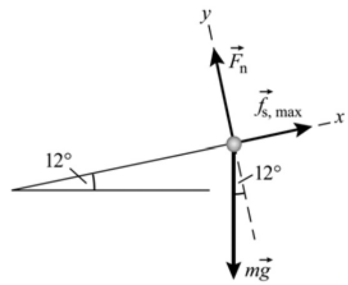
$$a_2 = \frac{\mu_k m_1 g}{m_2}$$

Substitute numerical values and evaluate a_2:

$$a_2 = \frac{(0.238)(60\,\text{kg})(9.81\,\text{m/s}^2)}{100\,\text{kg}} = \boxed{1.40\,\text{m/s}^2}$$

***52 ••**

Picture the Problem The accelerations of the truck can be found by applying Newton's 2nd law of motion. The free-body diagram for the truck climbing the incline with maximum acceleration is shown to the right.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the truck when it is climbing the incline:

$$\Sigma F_x = f_{\text{s,max}} - mg\sin 12° = ma \quad (1)$$

and

$$\Sigma F_y = F_\text{n} - mg\cos 12° = 0 \quad (2)$$

Solve equation (2) for F_n and use the definition of $f_{\text{s,max}}$ to obtain:

$$f_{\text{s,max}} = \mu_\text{s} mg\cos 12° \quad (3)$$

Substitute equation (3) into equation (1) and solve for a:

$$a = g(\mu_\text{s}\cos 12° - \sin 12°)$$

Substitute numerical values and evaluate a:

$$a = (9.81\,\text{m/s}^2)[(0.85)\cos 12° - \sin 12°] = \boxed{6.12\,\text{m/s}^2}$$

(*b*) When the truck is descending the incline with maximum acceleration, the static friction force points down the incline; i.e., its direction is reversed on the FBD. Apply $\sum F_x = ma_x$ to the truck under these conditions:

$$-f_{\text{s,max}} - mg\sin 12° = ma \quad (4)$$

Substitute equation (3) into equation (4) and solve for a:

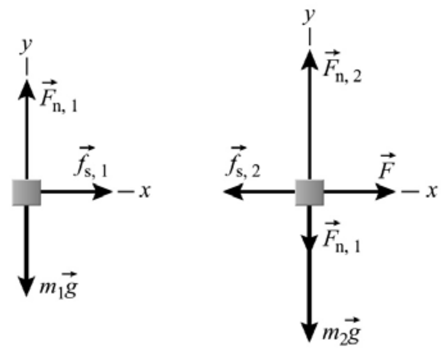
$$a = -g(\mu_\text{s}\cos 12° + \sin 12°)$$

Substitute numerical values and evaluate a:

$$a = (-9.81\,\text{m/s}^2)[(0.85)\cos 12° + \sin 12°] = \boxed{-10.2\,\text{m/s}^2}$$

53 ••

Picture the Problem The forces acting on each of the blocks are shown in the free-body diagrams to the right. m_1 represents the mass of the 2-kg block and m_2 that of the 4-kg block. As described by Newton's 3rd law, the normal reaction force $F_{n,1}$ and the friction force $f_{s,1}$ $(= f_{s,2})$ act on both objects but in opposite directions. Newton's 2nd law and the definition of the maximum static friction force can be used to determine the maximum force acting on the 4-kg block for which the 2-kg block does not slide.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the 2-kg block:

$\Sigma F_x = f_{s,1,max} = m_1 a_{max}$ (1)

and

$\Sigma F_y = F_{n,1} - m_1 g = 0$ (2)

Apply $\sum \vec{F} = m\vec{a}$ to the 4-kg block:

$\Sigma F_x = F - f_{s,2,max} = m_2 a_{max}$ (3)

and

$\Sigma F_y = F_{n,2} - F_{n,1} - m_2 g = 0$ (4)

Using equation (2), express the relationship between the static friction forces $\vec{f}_{s,1,max}$ and $\vec{f}_{s,2,max}$:

$f_{s,1,max} = f_{s,2,max} = \mu_s m_1 g$ (5)

Substitute (5) in (1) and solve for a_{max}:

$a_{max} = \mu_s g = (0.3)g = 2.94\text{ m/s}^2$

Solve equation (3) for $F = F_{max}$:

$$F_{max} = m_2 a_{max} + \mu_s m_1 g$$

Substitute numerical values and evaluate F_{max}:

$$F_{max} = (4\text{ kg})(2.94\text{ m/s}^2) + (0.3)(2\text{ kg}) \times (9.81\text{ m/s}^2) = \boxed{17.7\text{ N}}$$

(*b*) Use Newton's 2nd law to express the acceleration of the blocks moving as a unit:

$$a = \frac{F}{m_1 + m_2}$$

Substitute numerical values and evaluate a:

$$a = \frac{\frac{1}{2}(17.7\text{ N})}{2\text{ kg} + 4\text{ kg}} = \boxed{1.47\text{ m/s}^2}$$

Because the friction forces are an action-reaction pair, the friction force acting on each block is given by:

$f_s = m_1 a = (2\text{ kg})(1.47\text{ m/s}^2)$
$= \boxed{2.94\text{ N}}$

(*c*) If $F = 2F_{max}$, then m_1 slips on m_2 and the friction force (now kinetic) is given by:

$f = f_k = \mu_k m_1 g$

Use $\sum F_x = ma_x$ to relate the acceleration of the 2-kg block to the net force acting on it and solve for a_1:

$f_k = \mu_k m_1 g = m_1 a_1$
and
$a_1 = \mu_k g = (0.2)g = \boxed{1.96\text{ m/s}^2}$

Use $\sum F_x = ma_x$ to relate the acceleration of the 4-kg block to the net force acting on it:

$F - \mu_k m_1 g = m_2 a_2$

Solve for a_2:

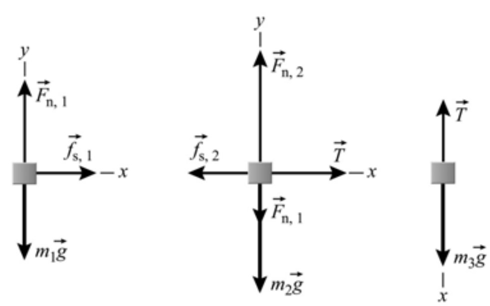
$$a_2 = \frac{F - \mu_k m_1 g}{m_2}$$

Substitute numerical values and evaluate a_2:

$$a_2 = \frac{2(17.7\text{ N}) - (0.2)(2\text{ kg})(9.81\text{ m/s}^2)}{4\text{ kg}}$$
$$= \boxed{7.87\text{ m/s}^2}$$

54 ••

Picture the Problem Let the positive *x* direction be the direction of motion of these blocks. The forces acting on each of the blocks are shown, for the static friction case, on the free-body diagrams to the right. As described by Newton's 3rd law, the normal reaction force $F_{n,1}$ and the friction force $f_{s,1}$ ($= f_{s,2}$) act on both objects but in opposite directions. Newton's 2nd law and the definition of the maximum static friction force can be used to determine the maximum acceleration of the block whose mass is m_1.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the 2-kg block:

$\Sigma F_x = f_{s,1,max} = m_1 a_{max}$ (1)
and

$$\Sigma F_y = F_{n,1} - m_1 g = 0 \quad (2)$$

Apply $\sum \vec{F} = m\vec{a}$ to the 4-kg block:

$$\Sigma F_x = T - f_{s,2,max} = m_2 a_{max} \quad (3)$$

and

$$\Sigma F_y = F_{n,2} - F_{n,1} - m_2 g = 0 \quad (4)$$

Using equation (2), express the relationship between the static friction forces $\vec{f}_{s,1,max}$ and $\vec{f}_{s,2,max}$:

$$f_{s,1,max} = f_{s,2,max} = \mu_s m_1 g \quad (5)$$

Substitute (5) in (1) and solve for a_{max}:

$$a_{max} = \mu_s g = (0.6)g = \boxed{5.89\,\text{m/s}^2}$$

(*b*) Use $\sum F_x = ma_x$ to express the acceleration of the blocks moving as a unit:

$$T = (m_1 + m_2)\, a_{max} \quad (6)$$

Apply $\sum F_x = ma_x$ to the object whose mass is m_3:

$$m_3 g - T = m_3 a_{max} \quad (7)$$

Add equations (6) and (7) to eliminate T and then solve for and evaluate m_3:

$$m_3 = \frac{\mu_s(m_1 + m_2)}{1 - \mu_s} = \frac{(0.6)(10\,\text{kg} + 5\,\text{kg})}{1 - 0.6} = \boxed{22.5\,\text{kg}}$$

(*c*) If m_3 = 30 kg, then m_1 will slide on m_2 and the friction force (now kinetic) is given by:

$$f = f_k = \mu_k m_1 g$$

Use $\sum F_x = ma_x$ to relate the acceleration of the 30-kg block to the net force acting on it:

$$m_3 g - T = m_3 a_3 \quad (8)$$

Noting that $a_2 = a_3$ and that the friction force on the body whose mass is m_2 is due to kinetic friction, add equations (3) and (8) and solve for and evaluate the common acceleration:

$$a_2 = a_3 = \frac{g(m_3 - \mu_k m_1)}{m_2 + m_3} = \frac{(9.81\,\text{m/s}^2)[30\,\text{kg} - (0.4)(5\,\text{kg})]}{10\,\text{kg} + 30\,\text{kg}} = \boxed{6.87\,\text{m/s}^2}$$

With block 1 sliding on block 2, the

$$f_k = \mu_k m_1 g = m_1 a_1 \quad (1')$$

friction force acting on each is kinetic and equations (1) and (3) become:

$$T - f_k = T - \mu_k m_1 g = m_2 a_2 \quad (3')$$

Solve equation (1′) for and evaluate a_1:

$$a_1 = \mu_k g = (0.4)(9.81\,\text{m/s}^2) = \boxed{3.92\,\text{m/s}^2}$$

Solve equation (3′) for T:

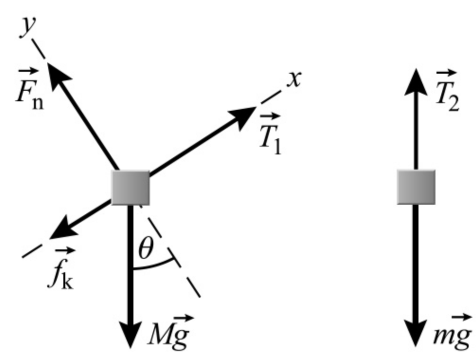
$$T = m_2 a_2 + \mu_k m_1 g$$

Substitute numerical values and evaluate T:

$$T = (10\,\text{kg})(6.87\,\text{m/s}^2) + (0.4)(5\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{88.3\,\text{N}}$$

55 •

Picture the Problem Let the direction of motion be the positive x direction. The free-body diagrams show the forces acting on both the block (M) and the counterweight (m). While $\vec{T}_1 \neq \vec{T}_2$, $T_1 = T_2$. By applying Newton's 2nd law to these blocks, we can obtain equations in T and a from which we can eliminate the tension. Once we know the acceleration of the block, we can use constant-acceleration equations to determine how far it moves in coming to a momentary stop.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the block on the incline:

$$\sum F_x = T_1 - Mg\sin\theta - f_k = Ma$$

and

$$\sum F_y = F_n - Mg\cos\theta = 0$$

Apply $\sum \vec{F} = m\vec{a}$ to the counterweight:

$$\sum F_x = mg - T_2 = ma \quad (1)$$

Letting $T_1 = T_2 = T$ and using the definition of the kinetic friction force, eliminate f_k and F_n between the equations for the block on the incline to obtain:

$$T - Mg\sin\theta - \mu_k Mg\cos\theta = Ma \quad (2)$$

Eliminate T from equations (1) and (2) by adding them and solve for a:

$$a = \frac{m - M(\sin\theta + \mu_k\cos\theta)}{m + M}g$$

Substitute numerical values and evaluate a:

$$a = \frac{550\,\text{kg} - (1600\,\text{kg})(\sin 10° + 0.15\cos 10°)}{550\,\text{kg} + 1600\,\text{kg}}(9.81\,\text{m/s}^2) = \boxed{0.163\,\text{m/s}^2}$$

(*b*) Using a constant-acceleration equation, relate the speed of the block at the instant the rope breaks to its acceleration and displacement as it slides to a stop. Solve for its displacement:

$$v_f^2 = v_i^2 + 2a\Delta x$$

or, because $v_f = 0$,

$$\Delta x = \frac{-v_i^2}{2a} \qquad (3)$$

The block had been accelerating up the incline for 3 s before the rope broke, so it has an initial speed of :

$$(0.163\text{ m/s}^2)(3\text{ s}) = 0.489\text{ m/s}$$

From equation (2) we can see that, when the rope breaks ($T = 0$) and:

$$\begin{aligned} a &= -g(\sin\theta + \mu_k \cos\theta) \\ &= -(9.81\,\text{m/s}^2)[\sin 10° + (0.15)\cos 10°] \\ &= -3.15\,\text{m/s}^2 \end{aligned}$$

where the minus sign indicates that the block is being accelerated down the incline, although it is still sliding up the incline.

Substitute in equation (3) and evaluate Δx:

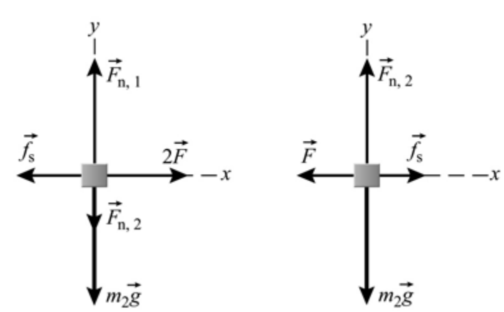
$$\Delta x = \frac{-(0.489\,\text{m/s})^2}{2(-3.15\,\text{m/s}^2)} = \boxed{0.0380\,\text{m}}$$

(*c*) When the block is sliding down the incline, the kinetic friction force will be up the incline. Express the block's acceleration:

$$\begin{aligned} a &= -g(\sin\theta - \mu_k \cos\theta) \\ &= -(9.81\,\text{m/s}^2)[\sin 10° - (0.15)\cos 10°] \\ &= \boxed{-0.254\,\text{m/s}^2} \end{aligned}$$

56 •••

Picture the Problem If the 10-kg block is not to slide on the bracket, the maximum value for $\vec{F}$ must be equal to the maximum value of f_s and will produce the maximum acceleration of this block and the bracket. We can apply Newton's 2nd law and the definition of $f_{s,max}$ to first calculate the maximum acceleration and then the maximum value of F.



(*a*) and (*b*) Apply $\sum \vec{F} = m\vec{a}$ to the 10-kg block when it is experiencing its maximum acceleration:

$$\Sigma F_x = f_{s,max} - F = m_2 a_{2,max} \qquad (1)$$

and

$$\Sigma F_y = F_{n,2} - m_2 g = 0 \qquad (2)$$

Express the static friction force acting on the 10-kg block:

$$f_{s,max} = \mu_s F_{n,2} \quad (3)$$

Eliminate $f_{s,max}$ and $F_{n,2}$ from equations (1), (2) and (3) to obtain:

$$\mu_s m_2 g - F = m_2 a_{2,max} \quad (4)$$

Apply $\sum F_x = ma_x$ to the bracket to obtain:

$$2F - \mu_s m_2 g = m_1 a_{1,max} \quad (5)$$

Because $a_{1,max} = a_{2,max}$, denote this acceleration by a_{max}. Eliminate F from equations (4) and (5) and solve for a_{max}:

$$a_{max} = \frac{\mu_s m_2 g}{m_1 + 2m_2}$$

Substitute numerical values and evaluate a_{max}:

$$a_{max} = \frac{(0.4)(10\,\text{kg})(9.81\,\text{m/s}^2)}{5\,\text{kg} + 2(10\,\text{kg})} = \boxed{1.57\,\text{m/s}^2}$$

Solve equation (4) for $F = F_{max}$:

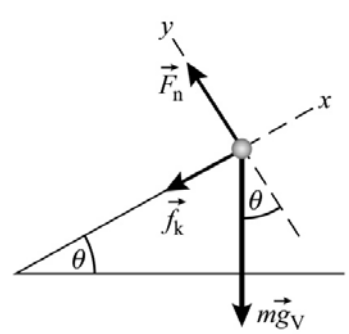
$$F = \mu_s m_2 g - m_2 a_{max} = m_2(\mu_s g - a_{max})$$

Substitute numerical values and evaluate F:

$$F = (10\,\text{kg})\left[(0.4)(9.81\,\text{m/s}^2) - 1.57\,\text{m/s}^2\right] = \boxed{23.5\,\text{N}}$$

***57** ••

Picture the Problem The free-body diagram shows the forces acting on the block as it is moving up the incline. By applying Newton's 2nd law, we can obtain expressions for the accelerations of the block up and down the incline. Adding and subtracting these equations, together with the data found in the notebook, will lead to values for g_V and μ_k.



Apply $\sum_i \vec{F}_i = m\vec{a}$ to the block when it is moving up the incline:

$$\sum F_x = -f_k - mg_V \sin\theta = ma_{up}$$

and

$$\sum F_y = F_n - mg_V \cos\theta = 0$$

Using the definition of f_k, eliminate F_n between the two equations to obtain:

$$a_{up} = -\mu_k g_V \cos\theta - g_V \sin\theta \quad (1)$$

When the block is moving down the incline, f_k is in the positive x direction, and its acceleration is:

$$a_{down} = \mu_k g_V \cos\theta - g_V \sin\theta \qquad (2)$$

Add equations (1) and (2) to obtain:

$$a_{up} + a_{down} = -2g_V \sin\theta \qquad (3)$$

Solve equation (3) for g_V:

$$g_V = \frac{a_{up} + a_{down}}{-2\sin\theta} \qquad (4)$$

Determine θ from the figure:

$$\theta = \tan^{-1}\left[\frac{0.73\,\text{glapp}}{3.82\,\text{glapp}}\right] = 10.8°$$

Substitute the data from the notebook in equation (4) to obtain:

$$g_V = \frac{1.73\,\text{glapp/plipp}^2 + 1.42\,\text{glapp/plipp}^2}{-2\sin 10.8°} = \boxed{-8.41\,\text{glapp/plipp}^2}$$

Subtract equation (1) from equation (2) to obtain:

$$a_{down} - a_{up} = 2\mu_k g_V \cos\theta$$

Solve for μ_k:

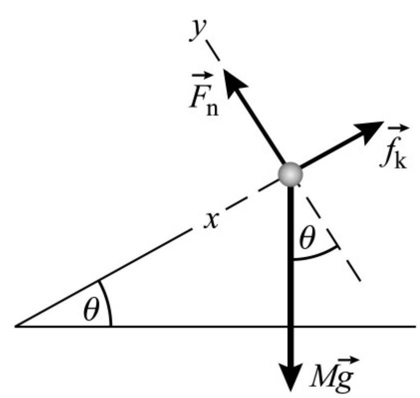
$$\mu_k = \frac{a_{down} - a_{up}}{2g_V \cos\theta}$$

Substitute numerical values and evaluate μ_k:

$$\mu_k = \frac{-1.42\,\text{glapp/plipp}^2 - 1.73\,\text{glapp/plipp}^2}{2\left(-8.41\,\text{glapp/plipp}^2\right)\cos 10.8°} = \boxed{0.191}$$

***58 ••**

Picture the Problem The free-body diagram shows the block sliding down the incline under the influence of a friction force, its weight, and the normal force exerted on it by the inclined surface. We can find the range of values for m for the two situations described in the problem statement by applying Newton's 2nd law of motion to, first, the conditions under which the block will not move or slide if pushed, and secondly, if pushed, the block will move up the incline.



(*a*) Assume that the block is sliding down the incline with a constant velocity and with no hanging weight (m = 0) and apply $\sum \vec{F} = m\vec{a}$ to

$$\sum F_x = -f_k + Mg\sin\theta = 0$$

and

$$\sum F_y = F_n - Mg\cos\theta = 0$$

the block:

Using $f_k = \mu_k F_n$, eliminate F_n between the two equations and solve for the net force acting on the block:

$$F_{net} = -\mu_k Mg\cos\theta + Mg\sin\theta$$

If the block is moving, this net force must be nonnegative and:

$$(-\mu_k \cos\theta + \sin\theta)Mg \geq 0$$

This condition requires that:

$$\mu_k \leq \tan\theta = \tan 18° = 0.325$$

Because $\mu_k = 0.2$, this condition is satisfied and:

$$m_{min} = 0$$

To find the maximum value, note that the maximum possible value for the tension in the rope is mg. For the block to move down the incline, the component of the block's weight parallel to the incline minus the frictional force must be greater than or equal to the tension in the rope:

$$Mg\sin\theta - \mu_k Mg\cos\theta \geq mg$$

Solve for m_{max}:

$$m_{max} \leq M(\sin\theta - \mu_k \cos\theta)$$

Substitute numerical values and evaluate m_{max}:

$$m_{max} \leq (100\,\text{kg})[\sin 18° - (0.2)\cos 18°] = 11.9\,\text{kg}$$

The range of values for m is:

$$\boxed{0 \leq m \leq 11.9\,\text{kg}}$$

(*b*) If the block is being dragged up the incline, the frictional force will point down the incline, and:

$$Mg\sin\theta + \mu_k Mg\cos\theta < mg$$

Solve for and evaluate m_{min}:

$$m_{min} > M(\sin\theta + \mu_k \cos\theta) = (100\text{ kg})[\sin 18° + (0.2)\cos 18°] = 49.9\,\text{kg}$$

If the block is not to move unless pushed:

$$Mg\sin\theta + \mu_s Mg\cos\theta > mg$$

Solve for and evaluate m_{max}:

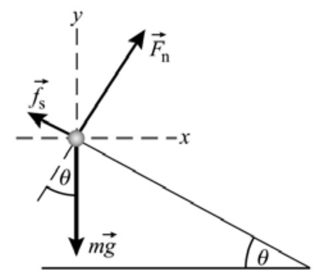
$$m_{max} < M(\sin\theta + \mu_s \cos\theta) = (100\text{ kg})[\sin 18° + (0.4)\cos 18°] = 68.9\,\text{kg}$$

The range of values for m is:

$$\boxed{49.9\,\text{kg} \leq m \leq 68.9\,\text{kg}}$$

59 •••

Picture the Problem The free-body diagram shows the forces acting on the 0.5 kg block when the acceleration is a minimum. Note the choice of coordinate system is consistent with the direction of $\vec{F}$. Apply Newton's 2nd law to the block and solve the resulting equations for a_{min} and a_{max}.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the 0.5-kg block:

$$\Sigma F_x = F_n \sin\theta - f_s \cos\theta = ma \qquad (1)$$

and

$$\Sigma F_y = F_n \cos\theta + f_s \sin\theta - mg = 0 \qquad (2)$$

Under minimum acceleration, $f_s = f_{s,max}$. Express the relationship between $f_{s,max}$ and F_n:

$$f_{s,max} = \mu_s F_n \qquad (3)$$

Substitute $f_{s,max}$ for f_s in equation (2) and solve for F_n:

$$F_n = \frac{mg}{\cos\theta + \mu_s \sin\theta}$$

Substitute for F_n in equation (1) and solve for $a = a_{min}$:

$$a_{min} = g\frac{\sin\theta - \mu_s \cos\theta}{\cos\theta + \mu_s \sin\theta}$$

Substitute numerical values and evaluate a_{min}:

$$a_{min} = \left(9.81\,\text{m/s}^2\right)\frac{\sin 35° - (0.8)\cos 35°}{\cos 35° + (0.8)\sin 35°} = -0.627\,\text{m/s}^2$$

Treat the block and incline as a single object to determine F_{min}:

$$F_{min} = m_{tot} a_{min} = (2.5\text{ kg})(-0.627\text{ m/s}^2) = \boxed{-1.57\,\text{N}}$$

To find the maximum acceleration, reverse the direction of $\vec{f}_s$ and apply $\sum \vec{F} = m\vec{a}$ to the block:

$$\Sigma F_x = F_n \sin\theta + f_s \cos\theta = ma \qquad (4)$$

and

$$\Sigma F_y = F_n \cos\theta - f_s \sin\theta - mg = 0 \qquad (5)$$

Proceed as above to obtain:

$$a_{max} = g\frac{\sin\theta + \mu_s \cos\theta}{\cos\theta - \mu_s \sin\theta}$$

Substitute numerical values and evaluate a_{max}:

$$a_{max} = \left(9.81\,\text{m/s}^2\right)\frac{\sin 35° + (0.8)\cos 35°}{\cos 35° - (0.8)\sin 35°} = 33.5\,\text{m/s}^2$$

Treat the block and incline as a single object to determine F_{max}:

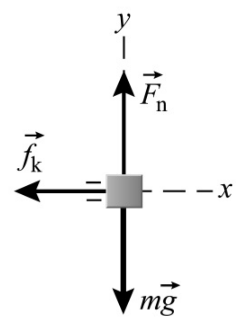
$$F_{max} = m_{tot}a_{max} = (2.5\text{ kg})(33.5\text{ m/s}^2) = \boxed{83.8\text{ N}}$$

(*b*) Repeat (*a*) with $\mu_s = 0.4$ to obtain:

$$F_{min} = \boxed{5.75\text{ N}} \text{ and } F_{max} = \boxed{37.5\text{ N}}$$

60 •

Picture the Problem The kinetic friction force f_k is the product of the coefficient of sliding friction μ_k and the normal force F_n the surface exerts on the sliding object. By applying Newton's 2nd law in the vertical direction, we can see that, on a horizontal surface, the normal force is the weight of the sliding object. Note that the acceleration of the block is opposite its direction of motion.



(*a*) Relate the force of kinetic friction to μ_k and the normal force acting on the sliding wooden object:

$$f_k = \mu_k F_n = \frac{0.11}{\left(1 + 2.3\times10^{-4}v^2\right)^2}mg$$

Substitute v = 10 m/s and evaluate f_k:

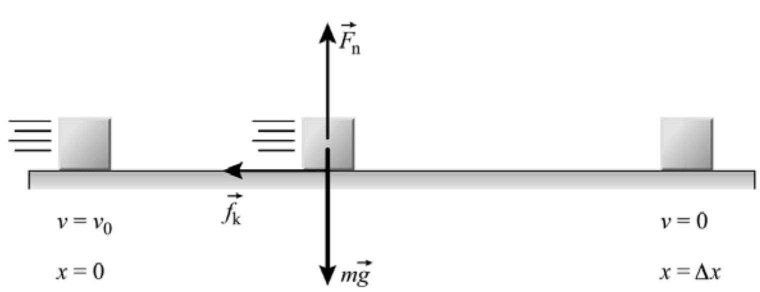
$$f_k = \frac{0.11(100\text{ kg})(9.81\text{ m/s}^2)}{\left(1 + 2.3\times10^{-4}(10\text{ m/s})^2\right)^2} = \boxed{103\text{ N}}$$

(*b*) Substitute v = 20 m/s and evaluate f_k:

$$f_k = \frac{0.11(100\text{ kg})(9.81\text{ m/s}^2)}{\left(1 + 2.3\times10^{-4}(20\text{ m/s})^2\right)^2} = \boxed{90.5\text{ N}}$$

61 ••

Picture the Problem The pictorial representation shows the block sliding from left to right and coming to rest when it has traveled a distance Δx. Note that the direction of the motion is opposite that of the block's acceleration. The acceleration and stopping distance of the blocks can be found from constant-acceleration equations. Let the direction of motion of the sliding blocks be the positive x direction. Because the surface is horizontal, the normal force acting on the sliding block is the block's weight.



(*a*) Using a constant-acceleration equation, relate the block's stopping distance to its initial speed and acceleration; solve for the stopping distance:

$$v^2 = v_0^2 + 2a\Delta x$$

or, because $v = 0$,

$$\Delta x = \frac{-v_0^2}{2a} \qquad (1)$$

Apply $\sum F_x = ma_x$ to the sliding block, introduce Konecny's empirical expression, and solve for the block's acceleration:

$$a = \frac{F_{\text{net},x}}{m} = \frac{-f_\text{k}}{m} = -\frac{0.4F_\text{n}^{0.91}}{m} = -\frac{0.4(mg)^{0.91}}{m}$$

Evaluate a with $m = 10$ kg:

$$a = -\frac{(0.4)[(10\,\text{kg})(9.81\,\text{m/s}^2)]^{0.91}}{10\,\text{kg}} = \boxed{-2.60\,\text{m/s}^2}$$

Substitute in equation (1) and evaluate the stopping distance when $v_0 = 10$ m/s:

$$\Delta x = \frac{-(10\,\text{m/s})^2}{2(-2.60\,\text{m/s}^2)} = \boxed{19.2\,\text{m}}$$

(*b*) Proceed as in (*a*) with $m = 100$ kg to obtain:

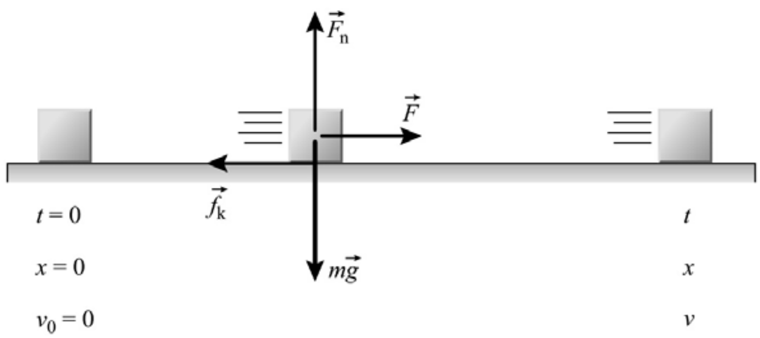
$$a = -\frac{(0.4)[(100\,\text{kg})(9.81\,\text{m/s}^2)]^{0.91}}{100\,\text{kg}} = \boxed{-2.11\,\text{m/s}^2}$$

Find the stopping distance as in (*a*):

$$\Delta x = \frac{-(10\,\text{m/s})^2}{2(-2.11\,\text{m/s}^2)} = \boxed{23.7\,\text{m}}$$

***62** •••

Picture the Problem The kinetic friction force f_k is the product of the coefficient of sliding friction μ_k and the normal force F_n the surface exerts on the sliding object. By applying Newton's 2nd law in the vertical direction, we can see that, on a horizontal surface, the normal force is the weight of the sliding object. We can apply Newton's 2nd law in the horizontal (x) direction to relate the block's acceleration to the net force acting on it. In the spreadsheet program, we'll find the acceleration of the block from this net force (which is velocity dependent), calculate the increase in the block's speed from its acceleration and the elapsed time and add this increase to its speed at end of the previous time interval, determine how far it has moved in this time interval, and add this distance to its previous position to find its current position. We'll also calculate the position of the block x_2, under the assumption that $\mu_\text{k} = 0.11$, using a constant-acceleration equation.



The spreadsheet solution is shown below. The formulas used to calculate the quantities in the columns are as follows:

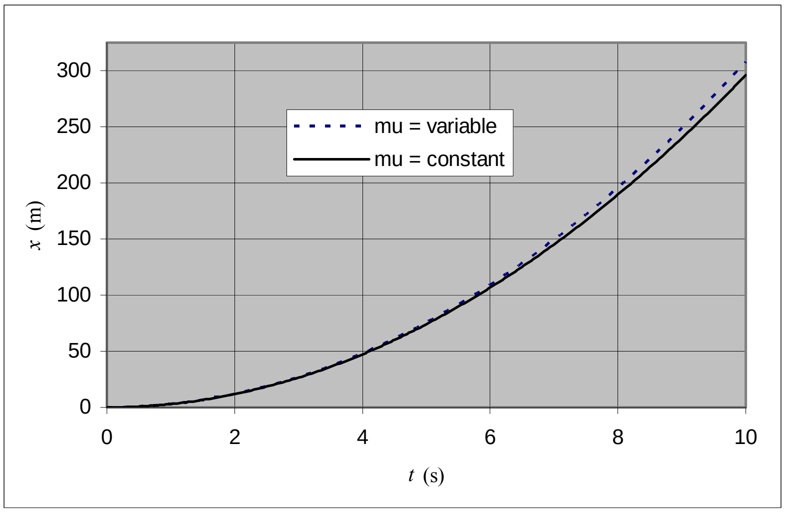
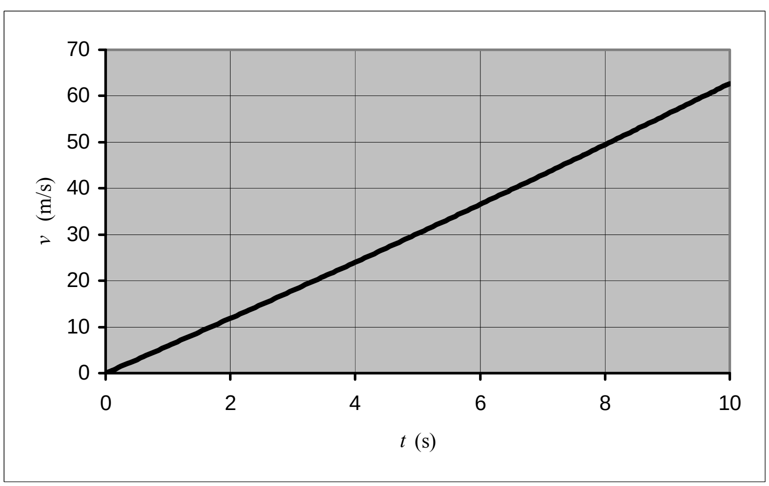
The displacement of the block as a function of time, for a constant coefficient of friction ($\mu_k = 0.11$) is shown as a solid line on the graph and for a variable coefficient of friction, is shown as a dotted line. Because the coefficient of friction decreases with increasing particle speed, the particle travels slightly farther when the coefficient of friction is variable.

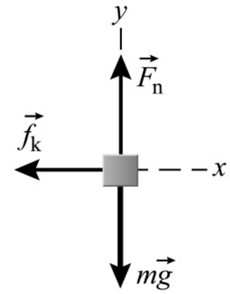


The velocity of the block, with variable coefficient of kinetic friction, is shown below.



63 ••

Picture the Problem The free-body diagram shows the forces acting on the block as it moves to the right. The kinetic friction force will slow the block and, eventually, bring it to rest. We can relate the coefficient of kinetic friction to the stopping time and distance by applying Newton's 2nd law and then using constant-acceleration equations.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the block of wood:

$$\sum F_x = -f_k = ma$$

and

$$\sum F_y = F_n - mg = 0$$

Using the definition of f_k, eliminate F_n between the two equations to obtain:

$$a = -\mu_k g \qquad (1)$$

Use a constant-acceleration equation to relate the acceleration of the block to its displacement and its stopping time:

$$\Delta x = v_0 \Delta t + \tfrac{1}{2} a (\Delta t)^2 \qquad (2)$$

Relate the initial speed of the block, v_0, to its displacement and stopping distance:

$$\Delta x = v_{av} \Delta t = \frac{v_0 + v}{2} \Delta t = \tfrac{1}{2} v_0 \Delta t \text{ since } v = 0. \qquad (3)$$

Use this result to eliminate v_0 in equation (2):

$$\Delta x = -\tfrac{1}{2} a (\Delta t)^2 \qquad (4)$$

Substitute equation (1) in equation (4) and solve for μ_k:

$$\mu_k = \frac{2\Delta x}{g(\Delta t)^2}$$

Substitute for Δx = 1.37 m and Δt = 0.97 s to obtain:

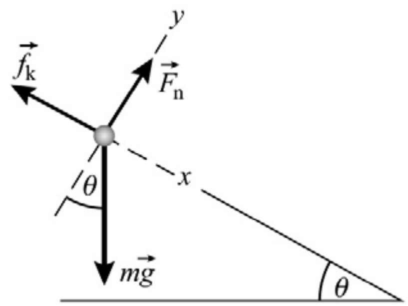
$$\mu_k = \frac{2(1.37\,\text{m})}{(9.81\,\text{m/s}^2)(0.97\,\text{s})^2} = \boxed{0.297}$$

(*b*) Use equation (3) to find v_0:

$$v_0 = \frac{2\Delta x}{\Delta t} = \frac{2(1.37\,\text{m})}{0.97\,\text{s}} = \boxed{2.82\,\text{m/s}}$$

***64** ••

Picture the Problem The free-body diagram shows the forces acting on the block as it slides down an incline. We can apply Newton's 2nd law to these forces to obtain the acceleration of the block and then manipulate this expression algebraically to show that a graph of $a/\cos\theta$ versus $\tan\theta$ will be linear with a slope equal to the acceleration due to gravity and an intercept whose absolute value is the coefficient of kinetic friction.



(*a*) Apply $\sum\vec{F} = m\vec{a}$ to the block as it slides down the incline:

$$\sum F_x = mg\sin\theta - f_k = ma$$

and

$$\sum F_y = F_n - mg\cos\theta = 0$$

Substitute $\mu_k F_n$ for f_k and eliminate F_n between the two equations to obtain:

$$a = g(\sin\theta - \mu_k\cos\theta)$$

Divide both sides of this equation by $\cos\theta$ to obtain:

$$\frac{a}{\cos\theta} = g\tan\theta - g\mu_k$$

Note that this equation is of the form $y = mx + b$:

Thus, if we graph $a/\cos\theta$ versus $\tan\theta$, we should get a straight line with slope g and y-intercept $-g\mu_k$.

(*b*) A spreadsheet solution is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
C7	θ	
D7	a	
E7	TAN(C7*PI()/180)	$\tan\left(\theta\times\frac{\pi}{180}\right)$
F7	D7/COS(C7*PI()/180)	$\frac{a}{\cos\left(\theta\times\frac{\pi}{180}\right)}$

	C	D	E	F
6	theta	a	tan(theta)	a/cos(theta)
7	25	1.691	0.466	1.866

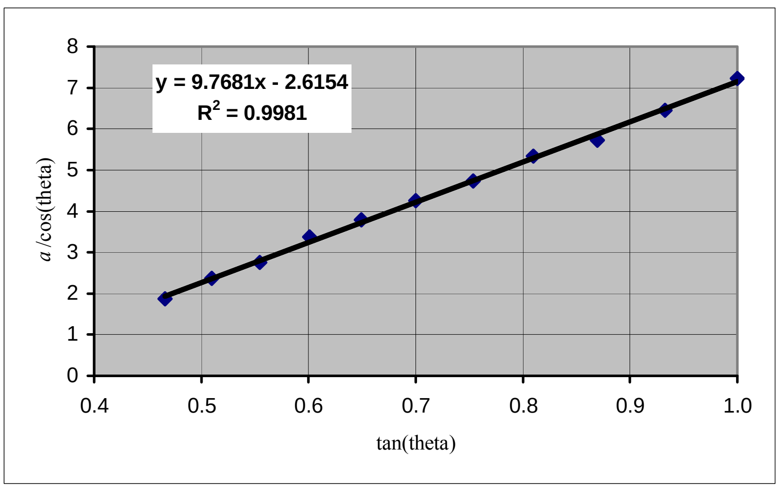
12	35	3.489	0.700	4.259
13	37	3.781	0.754	4.735
14	39	4.149	0.810	5.338
15	41	4.326	0.869	5.732
16	43	4.718	0.933	6.451
17	45	5.106	1.000	7.220

A graph of $a/\cos\theta$ versus $\tan\theta$ is shown below. From the curve fit (Excel's Trendline was used), $g = 9.77$ m/s^2 and $\mu_k = \dfrac{2.62\text{ m/s}^2}{9.77\text{ m/s}^2} = 0.268.$

The percentage error in g from the commonly accepted value of 9.81 m/s^2 is

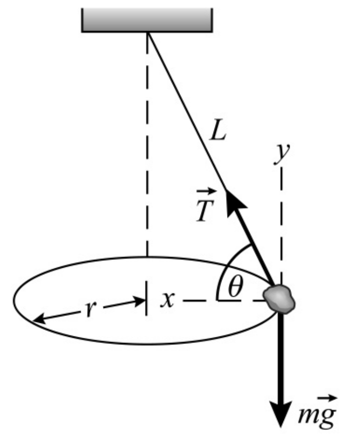
$$100\left(\frac{9.81\text{ m/s}^2 - 9.77\text{ m/s}^2}{9.81\text{ m/s}^2}\right) = \boxed{0.408\%}$$



Motion Along a Curved Path

65 •

Picture the Problem The free-body diagram showing the forces acting on the stone is superimposed on a sketch of the stone rotating in a horizontal circle. The only forces acting on the stone are the tension in the string and the gravitational force. The centripetal force required to maintain the circular motion is a component of the tension. We'll solve the problem for the general case in which the angle with the horizontal is θ by applying Newton's 2nd law of motion to the forces acting on the stone.



Apply $\sum \vec{F} = m\vec{a}$ to the stone:

$\Sigma F_x = T\cos\theta = ma_c = mv^2/r$ (1)

and

$\Sigma F_y = T\sin\theta - mg = 0$ (2)

Use the right triangle in the diagram to relate r, L, and θ:

$r = L\cos\theta$ (3)

Eliminate T and r between equations (1), (2) and (3) and solve for v_2:

$v^2 = gL\cot\theta\cos\theta$ (4)

Express the velocity of the stone in terms of its period:

$$v = \frac{2\pi r}{t_{1\,\text{rev}}} \quad (5)$$

Eliminate v between equations (4) and (5) and solve for θ:

$$\theta = \sin^{-1}\left(\frac{gt_{1\,\text{rev}}^2}{4\pi^2 L}\right)$$

Substitute numerical values and evaluate θ:

$$\theta = \sin^{-1}\left[\frac{(9.81\,\text{m/s}^2)(1.22\,\text{s})^2}{4\pi^2(0.85\,\text{m})}\right] = 25.8°$$

and $\boxed{(c)\text{ is correct.}}$

66 •

(*b*) Solve equation (2) for T:

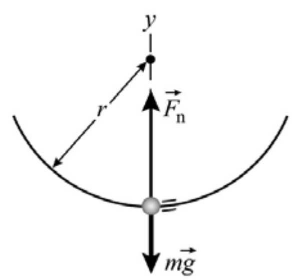
$$T = \frac{mg}{\cos\theta}$$

Substitute numerical values and evaluate T:

$$T = \frac{(0.75\,\text{kg})(9.81\,\text{m/s}^2)}{\cos 30°} = \boxed{8.50\,\text{N}}$$

***68** ••

Picture the Problem The sketch shows the forces acting on the pilot when her plane is at the lowest point of its dive. $\vec{F}_n$ is the force the airplane seat exerts on her. We'll apply Newton's 2nd law for circular motion to determine F_n and the radius of the circular path followed by the airplane.



(*a*) Apply $\sum F_y = ma_y$ to the pilot:

$$F_n - mg = ma_c$$

Solve for and evaluate F_n:

$$F_n = mg + ma_c = m(g + a_c) = m(g + 8.5g) = 9.5mg = (9.5)(50\text{ kg})(9.81\text{ m/s}^2) = \boxed{4.66\,\text{kN}}$$

(*b*) Relate her acceleration to her velocity and the radius of the circular arc and solve for the radius:

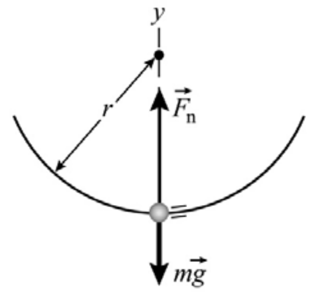
$$a_c = \frac{v^2}{r} \Rightarrow r = \frac{v^2}{a_c}$$

Substitute numerical values and evaluate r :

$$r = \frac{[(345\,\text{km/h})(1\,\text{h}/3600\,\text{s})(1000\,\text{m/km})]^2}{8.5(9.81\,\text{m/s}^2)} = \boxed{110\,\text{m}}$$

69 ••

Picture the Problem The diagram shows the forces acting on the pilot when her plane is at the lowest point of its dive. $\vec{F}_n$ is the force the airplane seat exerts on her. We'll use the definitions of centripetal acceleration and centripetal force and apply Newton's 2nd law to calculate these quantities and the normal force acting on her.



(*a*) Her acceleration is centripetal and given by:

$$a_c = \frac{v^2}{r}\text{, upward}$$

Substitute numerical values and evaluate a_c:

$$a_c = \frac{[(180\,\text{km/h})(1\,\text{h}/3600\,\text{s})(10^3\,/\text{km})]^2}{300\,\text{m}}$$

$$= \boxed{8.33\,\text{m/s}^2\text{, upward}}$$

(*b*) The net force acting on her at the bottom of the circle is the force responsible for her centripetal acceleration:

$$F_{net} = ma_c = (65\,\text{kg})(8.33\,\text{m/s}^2)$$

$$= \boxed{541\,\text{N, upward}}$$

(*c*) Apply $\sum F_y = ma_y$ to the pilot:

$$F_n - mg = ma_c$$

Solve for F_n:

$$F_n = mg + ma_c = m(g + a_c)$$

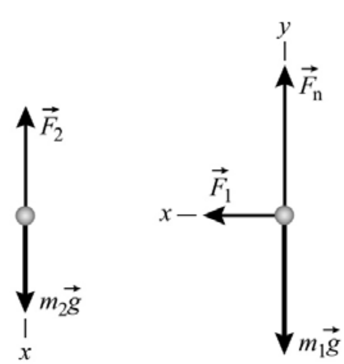
Substitute numerical values and evaluate F_n:

$$F_n = (65\text{ kg})(9.81\text{ m/s}^2 + 8.33\text{ m/s}^2)$$

$$= \boxed{1.18\,\text{kN, upward}}$$

70 ••

Picture the Problem The free-body diagrams for the two objects are shown to the right. The hole in the table changes the direction the tension in the string (which provides the centripetal force required to keep the object moving in a circular path) acts. The application of Newton's 2nd law and the definition of centripetal force will lead us to an expression for r as a function of m_1, m_2, and the time T for one revolution.



Apply $\sum F_x = ma_x$ to both objects and use the definition of centripetal acceleration to obtain:

$m_2g - F_2 = 0$
and
$F_1 = m_1a_c = m_1v^2/r$

Because $F_1 = F_2$ we can eliminate both of them between these equations to obtain:

$$m_2g - m_1\frac{v^2}{r} = 0$$

Express the speed v of the object in terms of the distance it travels each revolution and the time T for one revolution:

$$v = \frac{2\pi r}{T}$$

Substitute to obtain:

$$m_2g - m_1\frac{4\pi^2r^2}{rT^2} = 0$$

or

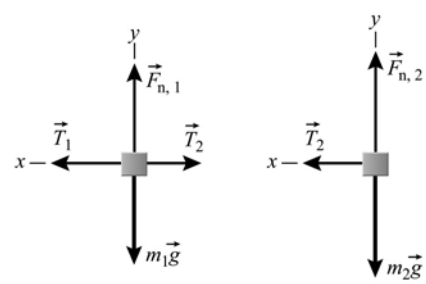
$$m_2g - m_1\frac{4\pi^2r}{T^2} = 0$$

Solve for r:

$$r = \boxed{\frac{m_2gT^2}{4\pi^2m_1}}$$

***71** ••

Picture the Problem The free-body diagrams show the forces acting on each block. We can use Newton's 2nd law to relate these forces to each other and to the masses and accelerations of the blocks.



Apply $\sum F_x = ma_x$ to the block whose mass is m_1:

$$T_1 - T_2 = m_1\frac{v_1^2}{L_1}$$

Apply $\sum F_x = ma_x$ to the block whose mass is m_2:

$$T_2 = m_2\frac{v_2^2}{L_1 + L_2}$$

Relate the speeds of each block to their common period and their distance from the center of the

$$v_1 = \frac{2\pi L_1}{T} \text{ and } v_2 = \frac{2\pi(L_1 + L_2)}{T}$$

circle:

Solve the first force equation for T_2, substitute for v_2, and simplify to obtain:

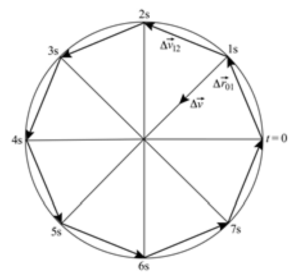
$$\boxed{T_2 = [m_2(L_1 + L_2)]\left(\frac{2\pi}{T}\right)^2}$$

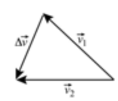
Substitute for T_2 and v_1 in the first force equation to obtain:

$$\boxed{T_1 = [m_2(L_1 + L_2) + m_1L_1]\left(\frac{2\pi}{T}\right)^2}$$

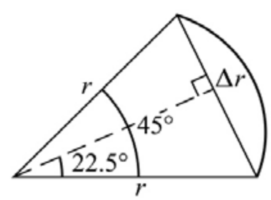
***72 ••**

Picture the Problem The path of the particle and its position at 1-s intervals are shown. The displacement vectors are also shown. The velocity vectors for the average velocities in the first and second intervals are along $\vec{r}_{01}$ and $\vec{r}_{12}$, respectively, and are shown in the lower diagram. $\Delta\vec{v}$ points toward the center of the circle.





Use the diagram to the right to find Δr:



$\Delta r = 2r\sin 22.5° = 2(4\text{ cm})\sin 22.5°$
$= 3.06\text{ cm}$

Find the average velocity of the particle along the chords:

$v_{av} = \Delta r/\Delta t = (3.06\text{ cm})/(1\text{ s})$
$= 3.06\text{ cm/s}$

Using the lower diagram and the fact that the angle between $\vec{v}_1$ and $\vec{v}_2$ is 45°, express Δv in terms of v_1 ($= v_2$):

$\Delta v = 2v_1\sin 22.5°$

Evaluate Δv using v_{av} as v_1:

$\Delta v = 2(3.06\text{ cm/s})\sin 22.5° = 2.34\text{ cm/s}$

Now we can determine $a = \Delta v/\Delta t$:

$$a = \frac{2.34\text{ cm/s}}{1\text{ s}} = \boxed{2.34\text{ cm/s}^2}$$

Find the speed v (= $v_1 = v_2$ …) of the particle along its circular path:

$$v = \frac{2\pi r}{T} = \frac{2\pi(4\,\text{cm})}{8\,\text{s}} = 3.14\,\text{cm/s}$$

Calculate the radial acceleration of the particle:

$$a_c = \frac{v^2}{r} = \frac{(3.14\,\text{cm/s})^2}{4\,\text{cm}} = \boxed{2.46\,\text{cm/s}^2}$$

Compare a_c and a by taking their ratio:

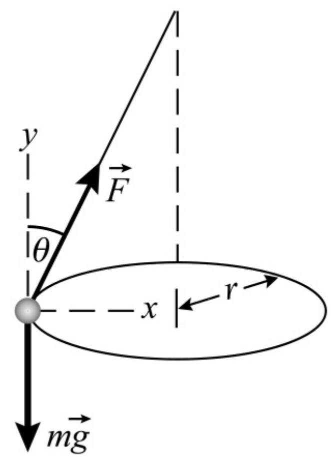
$$\frac{a_c}{a} = \frac{2.46\,\text{cm/s}^2}{2.34\,\text{cm/s}^2} = 1.05$$

or

$$\boxed{a_c = 1.05a}$$

73 ••

Picture the Problem The diagram to the right has the free-body diagram for the child superimposed on a pictorial representation of her motion. The force her father exerts is $\vec{F}$ and the angle it makes with respect to the direction we've chosen as the positive y direction is θ. We can infer her speed from the given information concerning the radius of her path and the period of her motion. Applying Newton's 2nd law as it describes circular motion will allow us to find both the direction and magnitude of $\vec{F}$.



Apply $\sum\vec{F} = m\vec{a}$ to the child:

$$\Sigma F_x = F\sin\theta = mv^2/r$$

and

$$\Sigma F_y = F\cos\theta - mg = 0$$

Eliminate F between these equations and solve for θ:

$$\theta = \tan^{-1}\left[\frac{v^2}{rg}\right]$$

Express v in terms of the radius and period of the child's motion:

$$v = \frac{2\pi r}{T}$$

Substitute for v in the expression for θ to obtain:

$$\theta = \tan^{-1}\left[\frac{4\pi^2 r}{gT^2}\right]$$

Substitute numerical values and evaluate θ:

$$\theta = \tan^{-1}\left[\frac{4\pi^2(0.75\,\text{m})}{(9.81\,\text{m/s}^2)(1.5\,\text{s})^2}\right] = \boxed{53.3°}$$

Solve the y equation for F:

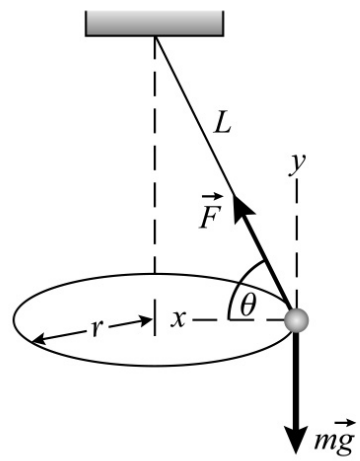
$$F = \frac{mg}{\cos\theta}$$

Substitute numerical values and evaluate F:

$$F = \frac{(25\,\text{kg})(9.81\,\text{m/s}^2)}{\cos 53.3°} = \boxed{410\,\text{N}}$$

74 ••

Picture the Problem The diagram to the right has the free-body diagram for the bob of the conical pendulum superimposed on a pictorial representation of its motion. The tension in the string is $\vec{F}$ and the angle it makes with respect to the direction we've chosen as the positive x direction is θ. We can find θ from the y equation and the information provided about the tension. Then, by using the definition of the speed of the bob in its orbit and applying Newton's 2nd law as it describes circular motion, we can find the period T of the motion.



Apply $\sum\vec{F} = m\vec{a}$ to the pendulum bob:

$$\Sigma F_x = F\cos\theta = mv^2/r$$
and
$$\Sigma F_y = F\sin\theta - mg = 0$$

Using the given information that $F = 6mg$, solve the y equation for θ:

$$\theta = \sin^{-1}\left(\frac{mg}{F}\right) = \sin^{-1}\left(\frac{mg}{6mg}\right) = 9.59°$$

With $F = 6mg$, solve the x equation for v:

$$v = \sqrt{6rg\cos\theta}$$

Relate the period T of the motion to the speed of the bob and the radius of the circle in which it moves:

$$T = \frac{2\pi r}{v} = \frac{2\pi r}{\sqrt{6rg\cos\theta}}$$

From the diagram, one can see that:

$$r = L\cos\theta$$

Substitute for r in the expression for the period to obtain:

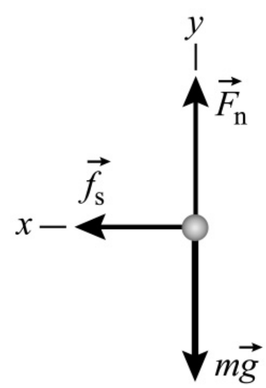
$$T = 2\pi\sqrt{\frac{L}{6g}}$$

Substitute numerical values and evaluate T:

$$T = 2\pi\sqrt{\frac{0.5\,\text{m}}{6(9.81\,\text{m/s}^2)}} = \boxed{0.579\,\text{s}}$$

75 ••

Picture the Problem The static friction force f_s is responsible for keeping the coin from sliding on the turntable. Using Newton's 2nd law of motion, the definition of the period of the coin's motion, and the definition of the maximum static friction force, we can find the magnitude of the friction force and the value of the coefficient of static friction for the two surfaces.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the coin:

$$\sum F_x = f_s = m\frac{v^2}{r}$$

and

$$\sum F_y = F_n - mg = 0$$

If T is the period of the coin's motion, its speed is given by:

$$v = \frac{2\pi r}{T}$$

Substitute for v in the force equation and simplify to obtain:

$$f_s = \frac{4\pi^2 mr}{T^2}$$

Substitute numerical values and evaluate f_s:

$$f_s = \frac{4\pi^2((0.1\,\text{kg})(0.1\,\text{m})}{(1\,\text{s})^2} = \boxed{0.395\,\text{N}}$$

(*b*) Determine F_n from the y equation:

$$F_n = mg$$

If the coin is about to slide at $r = 16$ cm, $f_s = f_{s,\text{max}}$. Solve for μ_s in terms of $f_{s,\text{max}}$ and F_n:

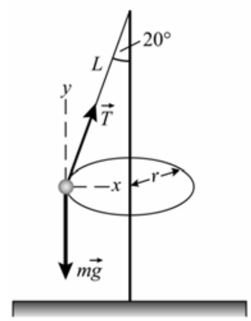
$$\mu_s = \frac{f_{s,\text{max}}}{F_n} = \frac{\frac{4\pi^2 mr}{T^2}}{mg} = \frac{4\pi^2 r}{gT^2}$$

Substitute numerical values and evaluate μ_s:

$$\mu_s = \frac{4\pi^2(0.16\,\text{m})}{(9.81\,\text{m/s}^2)(1\,\text{s})^2} = \boxed{0.644}$$

76 ••

Picture the Problem The forces acting on the tetherball are shown superimposed on a pictorial representation of the motion. The horizontal component of $\vec{T}$ is the centripetal force. Applying Newton's 2nd law of motion and solving the resulting equations will yield both the tension in the cord and the speed of the ball.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the tetherball:

$$\sum F_x = T\sin 20° = m\frac{v^2}{r}$$

and

$$\sum F_y = T\cos 20° - mg = 0$$

Solve the *y* equation for *T*:

$$T = \frac{mg}{\cos 20°}$$

Substitute numerical values and evaluate *T*:

$$T = \frac{(0.25\,\text{kg})(9.81\,\text{m/s}^2)}{\cos 20°} = \boxed{2.61\,\text{N}}$$

(*b*) Eliminate *T* between the force equations and solve for *v*:

$$v = \sqrt{rg\tan 20°}$$

Note from the diagram that:

$$r = L\sin 20°$$

Substitute for *r* in the expression for *v* to obtain:

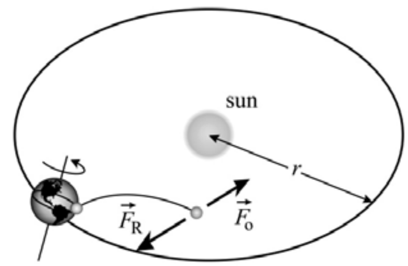
$$v = \sqrt{gL\sin 20°\tan 20°}$$

Substitute numerical values and evaluate *v*:

$$v = \sqrt{(9.81\,\text{m/s}^2)(1.2\,\text{m})\sin 20°\tan 20°} = \boxed{1.21\,\text{m/s}}$$

***77 ••**

Picture the Problem The diagram includes a pictorial representation of the earth in its orbit about the sun and a force diagram showing the force on an object at the equator that is due to the earth's rotation, $\vec{F}_R$, and the force on the object due to the orbital motion of the earth about the sun, $\vec{F}_o$. Because these are centripetal forces, we can calculate the accelerations they require from the speeds and radii associated with the two circular motions.



Express the radial acceleration due to the rotation of the earth:

$$a_R = \frac{v_R^2}{R}$$

Express the speed of the object on the equator in terms of the radius of the earth R and the period of the earth's rotation T_R:

$$v_R = \frac{2\pi R}{T_R}$$

Substitute for v_R in the expression for a_R to obtain:

$$a_R = \frac{4\pi^2 R}{T_R^2}$$

Substitute numerical values and evaluate a_R:

$$a_R = \frac{4\pi^2(6370\,\text{km})(1000\,\text{m/km})}{\left[(24\,\text{h})\left(\frac{3600\,\text{s}}{1\,\text{h}}\right)\right]^2}$$

$$= 3.37\times10^{-2}\,\text{m/s}^2$$

$$= \boxed{3.44\times10^{-3}\,g}$$

Express the radial acceleration due to the orbital motion of the earth:

$$a_o = \frac{v_o^2}{r}$$

Express the speed of the object on the equator in terms of the earth-sun distance r and the period of the earth's motion about the sun T_o:

$$v_o = \frac{2\pi r}{T_o}$$

Substitute for v_o in the expression for a_o to obtain:

$$a_o = \frac{4\pi^2 r}{T_o^2}$$

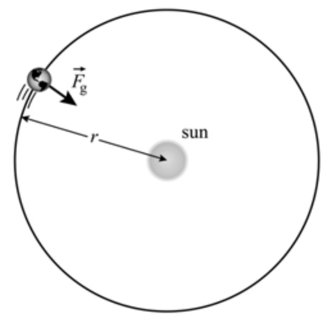
Substitute numerical values and evaluate a_c:

$$a_o = \frac{4\pi^2(1.5\times10^{11}\text{ m})}{\left[(365\text{ d})\left(\frac{24\text{ h}}{1\text{ d}}\right)\left(\frac{3600\text{ s}}{1\text{ h}}\right)\right]^2}$$

$$= 5.95\times10^{-3}\text{ m/s}^2 = \boxed{6.07\times10^{-4}\,g}$$

78 •

Picture the Problem The most significant force acting on the earth is the gravitational force exerted by the sun. More distant or less massive objects exert forces on the earth as well, but we can calculate the net force by considering the radial acceleration of the earth in its orbit. Similarly, we can calculate the net force acting on the moon by considering its radial acceleration in its orbit about the earth.



(*a*) Apply $\sum F_r = ma_r$ to the earth:

$$F_{\text{on earth}} = m\frac{v^2}{r}$$

Express the orbital speed of the earth in terms of the time it takes to make one trip around the sun (i.e., its period) and its average distance from the sun:

$$v = \frac{2\pi r}{T}$$

Substitute for v to obtain:

$$F_{\text{on earth}} = \frac{4\pi^2 mr}{T^2}$$

Substitute numerical values and evaluate $F_{\text{on earth}}$:

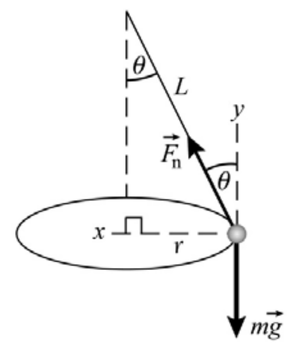
$$F_{\text{on earth}} = \frac{4\pi^2(5.98\times10^{24}\text{ kg})(1.496\times10^{11}\text{ m})}{\left(365.24\text{ d}\times\frac{24\text{ h}}{\text{d}}\times\frac{3600\text{ s}}{\text{h}}\right)^2} = \boxed{3.55\times10^{22}\text{ N}}$$

(*b*) Proceed as in (*a*) to obtain:

$$F_{\text{on moon}} = \frac{4\pi^2(7.35\times10^{22}\text{ kg})(3.844\times10^{8}\text{ m})}{\left(27.32\text{ d}\times\frac{24\text{ h}}{\text{d}}\times\frac{3600\text{ s}}{\text{h}}\right)^2} = \boxed{2.00\times10^{20}\text{ N}}$$

79 ••

Picture the Problem The semicircular wire of radius 10 cm limits the motion of the bead in the same manner as would a 10-cm string attached to the bead and fixed at the center of the semicircle. The horizontal component of the normal force the wire exerts on the bead is the centripetal force. The application of Newton's 2nd law, the definition of the speed of the bead in its orbit, and the relationship of the frequency of a circular motion to its period will yield the angle at which the bead will remain stationary relative to the rotating wire.



Apply $\sum \vec{F} = m\vec{a}$ to the bead:

$$\sum F_x = F_n \sin\theta = m\frac{v^2}{r}$$

and

$$\sum F_y = F_n \cos\theta - mg = 0$$

Eliminate F_n from the force equations to obtain:

$$\tan\theta = \frac{v^2}{rg}$$

The frequency of the motion is the reciprocal of its period T. Express the speed of the bead as a function of the radius of its path and its period:

$$v = \frac{2\pi r}{T}$$

Using the diagram, relate r to L and θ:

$$r = L\sin\theta$$

Substitute for r and v in the expression for $\tan\theta$ and solve for θ:

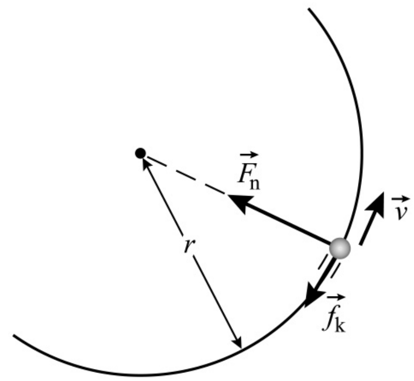
$$\theta = \cos^{-1}\left[\frac{gT^2}{4\pi^2 L}\right]$$

Substitute numerical values and evaluate θ:

$$\theta = \cos^{-1}\left[\frac{(9.81\,\text{m/s}^2)(0.5\,\text{s})^2}{4\pi^2(0.1\,\text{m})}\right] = \boxed{51.6^\circ}$$

80 •••

Picture the Problem Note that the acceleration of the bead has two components, the radial component perpendicular to $\vec{v}$, and a tangential component due to friction that is opposite to $\vec{v}$. The application of Newton's 2nd law will result in a differential equation with separable variables. Its integration will lead to an expression for the speed of the bead as a function of time.



Apply $\sum \vec{F} = m\vec{a}$ to the bead in the radial and tangential directions:

$$\sum F_r = F_n = m\frac{v^2}{r}$$

and

$$\sum F_t = -f_k = ma_t = m\frac{dv}{dt}$$

Express f_k in terms of μ_k and F_n:

$$f_k = \mu_k F_n$$

Substitute for F_n and f_k in the tangential equation to obtain the differential equation:

$$\frac{dv}{dt} = -\frac{\mu_k}{r}v^2$$

Separate the variables to obtain:

$$\frac{dv}{v^2} = -\frac{\mu_k}{r}dt$$

Express the integral of this equation with the limits of integration being from v_0 to v on the left-hand side and from 0 to t on the right-hand side:

$$\int_{v_0}^{v} \frac{1}{v'^2}dv' = -\frac{\mu_k}{r}\int_0^t dt'$$

Evaluate these integrals to obtain:

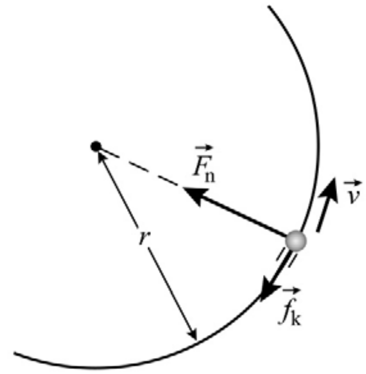
$$-\left(\frac{1}{v} - \frac{1}{v_0}\right) = -\left(\frac{\mu_k}{r}\right)t$$

Solve this equation for v:

$$\boxed{v = v_0\left(\frac{1}{1+\left(\frac{\mu_k v_0}{r}\right)t}\right)}$$

81 •••

Picture the Problem Note that the acceleration of the bead has two components–the radial component perpendicular to $\vec{v}$, and a tangential component due to friction that is opposite to $\vec{v}$. The application of Newton's 2nd law will result in a differential equation with separable variables. Its integration will lead to an expression for the speed of the bead as a function of time.



(*a*) In Problem 81 it was shown that:

$$v = v_0\left(\frac{1}{1+\left(\frac{\mu_k v_0}{r}\right)t}\right)$$

Express the centripetal acceleration of the bead:

$$a_c = \frac{v^2}{r} = \boxed{\frac{v_0^2}{r}\left(\frac{1}{1+\left(\frac{\mu_k v_0}{r}\right)t}\right)^2}$$

(*b*) Apply Newton's 2nd law to the bead:

$$\sum F_r = F_n = m\frac{v^2}{r}$$

and

$$\sum F_t = -f_k = ma_t = m\frac{dv}{dt}$$

Eliminate F_n and f_k to rewrite the radial force equation and solve for a_t:

$$a_t = -\mu_k\frac{v^2}{r} = \boxed{-\mu_k a_c}$$

(*c*) Express the resultant acceleration in terms of its radial and tangential components:

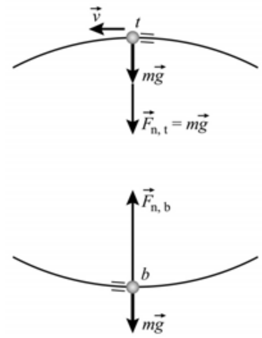
$$a = \sqrt{a_t^2 + a_c^2} = \sqrt{(-\mu_k a_c)^2 + a_c^2}$$

$$= \boxed{a_c\sqrt{1+\mu_k^2}}$$

Concepts of Centripetal Force

***82 •**

Picture the Problem The diagram depicts a seat at its highest and lowest points. Let "t" denote the top of the loop and "b" the bottom of the loop. Applying Newton's 2nd law to the seat at the top of the loop will establish the value of mv^2/r; this can then be used at the bottom of the loop to determine $F_{\text{n,b}}$.



Apply $\sum F_r = ma_r$ to the seat at the top of the loop:

$$mg + F_{\text{n,t}} = 2mg = ma_{\text{r}} = mv^2/r$$

Apply $\sum F_r = ma_r$ to the seat at the bottom of the loop:

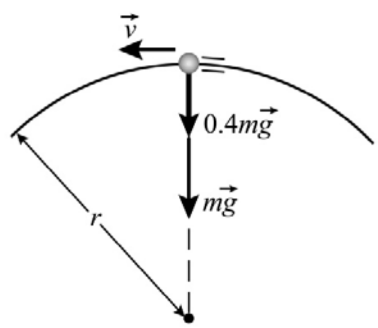
$$F_{\text{n,b}} - mg = mv^2/r$$

Solve for $F_{\text{n,b}}$ and substitute for mv^2/r to obtain:

$$F_{\text{n,b}} = 3mg \text{ and } \boxed{(d) \text{ is correct.}}$$

83 •

Picture the Problem The speed of the roller coaster is imbedded in the expression for its radial acceleration. The radial acceleration is determined by the net radial force acting on the passenger. We can use Newton's 2nd law to relate the net force on the passenger to the speed of the roller coaster.



Apply $\sum F_{\text{radial}} = ma_{\text{radial}}$ to the passenger:

$$mg + 0.4mg = mv^2/r$$

Solve for v:

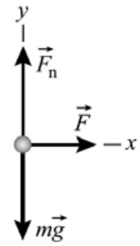
$$v = \sqrt{1.4gr}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{1.4(9.81\,\text{m/s}^2)(12.0\,\text{m})} = \boxed{12.8\,\text{m/s}}$$

84 •

Picture the Problem The force F the passenger exerts on the armrest of the car door is the radial force required to maintain the passenger's speed around the curve and is related to that speed through Newton's 2nd law of motion.



Apply $\sum F_x = ma_x$ to the forces acting on the passenger:

$$F = m\frac{v^2}{r}$$

Solve this equation for v:

$$v = \sqrt{\frac{rF}{m}}$$

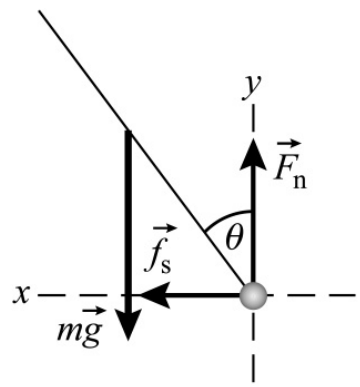
Substitute numerical values and evaluate v:

$$v = \sqrt{\frac{(80\,\text{m})(220\,\text{N})}{70\,\text{kg}}} = 15.9\,\text{m/s}$$

and $\boxed{(a)\text{ is correct.}}$

***85** •••

Picture the Problem The forces acting on the bicycle are shown in the force diagram. The static friction force is the centripetal force exerted by the surface on the bicycle that allows it to move in a circular path. $\vec{F}_n + \vec{f}_s$ makes an angle θ with the vertical direction. The application of Newton's 2nd law will allow us to relate this angle to the speed of the bicycle and the coefficient of static friction.



(a) Apply $\sum \vec{F} = m\vec{a}$ to the bicycle:

$$\sum F_x = f_s = \frac{mv^2}{r}$$

and

$$\sum F_y = F_n - mg = 0$$

Relate F_n and f_s to θ:

$$\tan\theta = \frac{f_s}{F_n} = \frac{\frac{mv^2}{r}}{mg} = \frac{v^2}{rg}$$

Solve for v:

$$v = \sqrt{rg\tan\theta}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{(20\,\text{m})(9.81\,\text{m/s}^2)\tan 15°} = \boxed{7.25\,\text{m/s}}$$

(b) Relate f_s to μ_s and F_n:

$$f_s = \tfrac{1}{2}f_{s,max} = \tfrac{1}{2}\mu_s mg$$

Solve for μ_s and substitute for f_s to obtain:

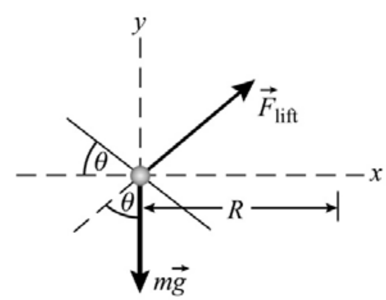
$$\mu_s = \frac{2f_s}{mg} = \frac{2v^2}{rg}$$

Substitute numerical values and evaluate μ_s

$$\mu_s = \frac{2(7.25\,\text{m/s})^2}{(20\,\text{m})(9.81\,\text{m/s}^2)} = \boxed{0.536}$$

86 ••

Picture the Problem The diagram shows the forces acting on the plane as it flies in a horizontal circle of radius R. We can apply Newton's 2nd law to the plane and eliminate the lift force in order to obtain an expression for R as a function of v and θ.



Apply $\sum \vec{F} = m\vec{a}$ to the plane:

$$\sum F_x = F_{lift}\sin\theta = m\frac{v^2}{R}$$

and

$$\sum F_y = F_{lift}\cos\theta - mg = 0$$

Eliminate F_{lift} between these equations to obtain:

$$\tan\theta = \frac{v^2}{Rg}$$

Solve for R:

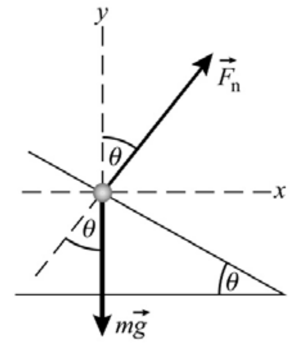
$$R = \frac{v^2}{g\tan\theta}$$

Substitute numerical values and evaluate R:

$$R = \frac{\left(480\frac{\text{km}}{\text{h}} \times \frac{1\,\text{h}}{3600\,\text{s}}\right)^2}{(9.81\,\text{m/s}^2)\tan 40°} = \boxed{2.16\,\text{km}}$$

87 •

Picture the Problem Under the conditions described in the problem statement, the only forces acting on the car are the normal force exerted by the road and the gravitational force exerted by the earth. The horizontal component of the normal force is the centripetal force. The application of Newton's 2nd law will allow us to express θ in terms of v, r, and g.



Apply $\sum \vec{F} = m\vec{a}$ to the car:

$$\sum F_x = F_n \sin\theta = m\frac{v^2}{r}$$

and

$$\sum F_y = F_n \cos\theta - mg = 0$$

Eliminate F_n from the force equations to obtain:

$$\tan\theta = \frac{v^2}{rg}$$

Solve for θ:

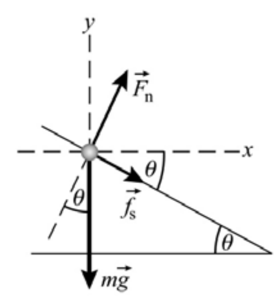
$$\theta = \tan^{-1}\left[\frac{v^2}{rg}\right]$$

Substitute numerical values and evaluate θ:

$$\theta = \tan^{-1}\left\{\frac{[(90\,\text{km/h})(1\,\text{h}/3600\,\text{s})(1000\,\text{m/km})]^2}{(160\,\text{m})(9.81\,\text{m/s}^2)}\right\} = \boxed{21.7°}$$

***88** ••

Picture the Problem Both the normal force and the static friction force contribute to the centripetal force in the situation described in this problem. We can apply Newton's 2nd law to relate f_s and F_n and then solve these equations simultaneously to determine each of these quantities.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the car:

$$\sum F_x = F_n \sin\theta + f_s \cos\theta = m\frac{v^2}{r}$$

and

$$\sum F_y = F_n \cos\theta - f_s \sin\theta - mg = 0$$

Multiply the *x* equation by $\sin\theta$ and the *y* equation by $\cos\theta$ to obtain:

$$f_s \sin\theta\cos\theta + F_n \sin^2\theta = m\frac{v^2}{r}\sin\theta$$

and

$$F_n \cos^2\theta - f_s \sin\theta\cos\theta - mg\cos\theta = 0$$

Add these equations to eliminate f_s:

$$F_n - mg\cos\theta = m\frac{v^2}{r}\sin\theta$$

Solve for F_n:

$$F_n = mg\cos\theta + m\frac{v^2}{r}\sin\theta = m\left(g\cos\theta + \frac{v^2}{r}\sin\theta\right)$$

Substitute numerical values and evaluate F_n:

$$F_n = (800\,\text{kg})\left[(9.81\,\text{m/s}^2)\cos10° + \frac{(85\,\text{km/h})^2(1000\,\text{m/km})^2(1\,\text{h}/3600\,\text{s})^2}{150\,\text{m}}\sin10°\right] = \boxed{8.25\,\text{kN}}$$

(*b*) Solve the *y* equation for f_s:

$$f_s = \frac{F_n\cos\theta - mg}{\sin\theta}$$

Substitute numerical values and evaluate f_s:

$$f_s = \frac{(8.25\,\text{kN})\cos10° - (800\,\text{kg})(9.81\,\text{m/s}^2)}{\sin10°} = \boxed{1.59\,\text{kN}}$$

(*c*) Express $\mu_{s,\min}$ in terms of f_s and F_n:

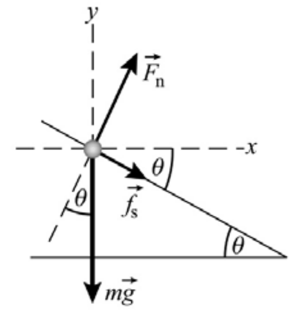
$$\mu_{s,\min} = \frac{f_s}{F_n}$$

Substitute numerical values and evaluate $\mu_{s,\min}$:

$$\mu_{s,\min} = \frac{1.59\ \text{kN}}{8.25\,\text{kN}} = \boxed{0.193}$$

89 ••

Picture the Problem Both the normal force and the static friction force contribute to the centripetal force in the situation described in this problem. We can apply Newton's 2nd law to relate f_s and F_n and then solve these equations simultaneously to determine each of these quantities.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the car:

$$\sum F_x = F_n \sin\theta + f_s \cos\theta = m\frac{v^2}{r}$$

$$\sum F_y = F_n \cos\theta - f_s \sin\theta - mg = 0$$

Multiply the x equation by $\sin\theta$ and the y equation by $\cos\theta$:

$$f_s \sin\theta\cos\theta + F_n \sin^2\theta = m\frac{v^2}{r}\sin\theta$$

$$F_n \cos^2\theta - f_s \sin\theta\cos\theta - mg\cos\theta = 0$$

Add these equations to eliminate f_s:

$$F_n - mg\cos\theta = m\frac{v^2}{r}\sin\theta$$

Solve for F_n:

$$F_n = mg\cos\theta + m\frac{v^2}{r}\sin\theta = m\left(g\cos\theta + \frac{v^2}{r}\sin\theta\right)$$

Substitute numerical values and evaluate F_n:

$$F_n = (800\,\text{kg})\left[(9.81\,\text{m/s}^2)\cos10° + \frac{(38\,\text{km/h})^2(1000\,\text{m/km})^2(1\,\text{h}/3600\,\text{s})^2}{150\,\text{m}}\sin10°\right] = \boxed{7.832\,\text{kN}}$$

(*b*) Solve the y equation for f_s:

$$f_s = \frac{F_n\cos\theta - mg}{\sin\theta} = F_n\cot\theta - \frac{mg}{\sin\theta}$$

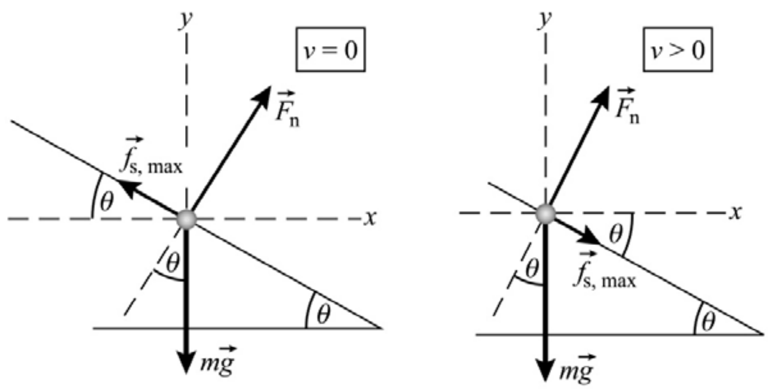
Substitute numerical values and evaluate f_s:

$$f_s = (7.832\,\text{kN})\cot 10° - \frac{(800\,\text{kg})(9.81\,\text{m/s}^2)}{\sin 10°} = \boxed{-777\,\text{N}}$$

The negative sign tells us that f_s points upward along the inclined plane rather than as shown in the force diagram.

***90 •••**

Picture the Problem The free-body diagram to the left is for the car at rest. The static friction force up the incline balances the downward component of the car's weight and prevents it from sliding. In the free-body diagram to the right, the static friction force points in the opposite direction as the tendency of the moving car is to slide toward the outside of the curve.



Apply $\sum \vec{F} = m\vec{a}$ to the car that is at rest:

$$\sum F_y = F_n \cos\theta + f_s \sin\theta - mg = 0 \quad (1)$$

and

$$\sum F_x = F_n \sin\theta - f_s \cos\theta = 0 \quad (2)$$

Substitute $f_s = f_{s,max} = \mu_s F_n$ in equation (2) and solve for and evaluate the maximum allowable value of θ:

$$\theta = \tan^{-1}(\mu_s) = \tan^{-1}(0.08) = \boxed{4.57°}$$

Apply $\sum \vec{F} = m\vec{a}$ to the car that is moving with speed v:

$$\sum F_y = F_n \cos\theta - f_s \sin\theta - mg = 0 \quad (3)$$

$$\sum F_x = F_n \sin\theta + f_s \cos\theta = m\frac{v^2}{r} \quad (4)$$

Substitute $f_s = \mu_s F_n$ in equations (3) and (4) and simplify to obtain:

$$F_n(\cos\theta - \mu_s \sin\theta) = mg \quad (5)$$

$$F_n(\mu_s \cos\theta + \sin\theta) = m\frac{v^2}{r} \quad (6)$$

Substitute numerical values into (5)

$$0.9904 F_n = mg$$

and (6) to obtain:

and

$$0.1595F_n = m\frac{v^2}{r}$$

Eliminate F_n and solve for r:

$$r = \frac{v^2}{0.1610g}$$

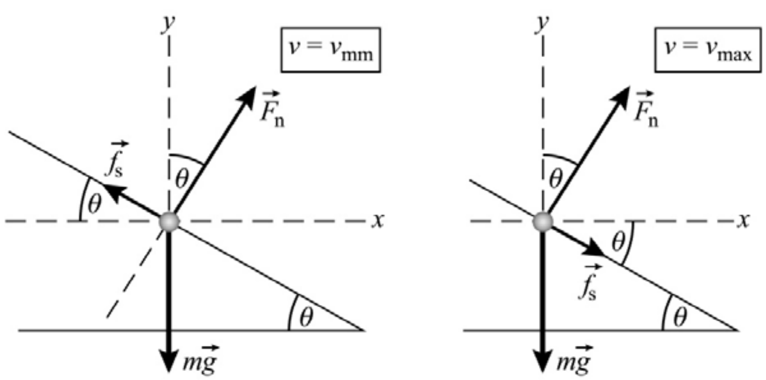
Substitute numerical values and evaluate r:

$$r = \frac{(60\,\text{km/h}\times 1\,\text{h}/3600\,\text{s}\times 1000\,\text{m/km})^2}{0.1610(9.81\,\text{m/s}^2)}$$

$$= \boxed{176\,\text{m}}$$

91 •••

Picture the Problem The free-body diagram to the left is for the car rounding the curve at the minimum (not sliding down the incline) speed. The static friction force up the incline balances the downward component of the car's weight and prevents it from sliding. In the free-body diagram to the right, the static friction force points in the opposite direction as the tendency of the car moving with the maximum safe speed is to slide toward the outside of the curve. Application of Newton's 2nd law and the simultaneous solution of the force equations will yield v_{min} and v_{max}.



Apply $\sum \vec{F} = m\vec{a}$ to a car traveling around the curve when the coefficient of static friction is zero:

$$\sum F_x = F_n \sin\theta = m\frac{v_{min}^2}{r}$$

and

$$\sum F_y = F_n \cos\theta - mg = 0$$

Divide the first of these equations by the second to obtain:

$$\tan\theta = \frac{v^2}{rg} \text{ or } \theta = \tan^{-1}\left(\frac{v^2}{rg}\right)$$

Substitute numerical values and evaluate the banking angle:

$$\theta = \tan^{-1}\left[\frac{(40\,\text{km/h})^2(1000\,\text{m/km})^2(1\text{h}/3600\,\text{s}^2)}{(30\,\text{m})(9.81\,\text{m/s}^2)}\right] = 22.8°$$

Apply $\sum \vec{F} = m\vec{a}$ to the car traveling around the curve at minimum speed:

$$\sum F_x = F_n \sin\theta - f_s \cos\theta = m\frac{v_{\text{min}}^2}{r}$$

and

$$\sum F_y = F_n \cos\theta + f_s \sin\theta - mg = 0$$

Substitute $f_s = f_{s,\text{max}} = \mu_s F_n$ in the force equations and simplify to obtain:

$$F_n(\mu_s \cos\theta - \sin\theta) = m\frac{v_{\text{min}}^2}{r}$$

and

$$F_n(\cos\theta + \mu_s \sin\theta) = mg$$

Evaluate these equations for $\theta = 22.8°$ and $\mu_s = 0.3$:

$$0.1102 F_n = m\frac{v_{\text{min}}^2}{r}$$

and

$$1.038 F_n = mg$$

Eliminate F_n between these two equations and solve for v_{min}:

$$v_{\text{min}} = \sqrt{0.106 rg}$$

Substitute numerical values and evaluate v_{min}:

$$v_{\text{min}} = \sqrt{0.106(30\,\text{m})(9.81\,\text{m/s}^2)} = \boxed{5.59\,\text{m/s} = 20.1\,\text{km/h}}$$

Apply $\sum \vec{F} = m\vec{a}$ to the car traveling around the curve at maximum speed:

$$\sum F_x = F_n \sin\theta + f_s \cos\theta = m\frac{v_{\text{max}}^2}{r}$$

and

$$\sum F_y = F_n \cos\theta - f_s \sin\theta - mg = 0$$

Substitute $f_s = f_{s,\text{max}} = \mu_s F_n$ in the force equations and simplify to obtain:

$$F_n(\mu_s \cos\theta + \sin\theta) = m\frac{v_{\text{max}}^2}{r}$$

and

$$F_n(\cos\theta - \mu_s \sin\theta) = mg$$

Evaluate these equations for $\theta = 22.8°$ and $\mu_s = 0.3$:

$$0.6641 F_n = m\frac{v_{\text{max}}^2}{r}$$

and

$$0.8056 F_n = mg$$

Eliminate F_n between these two equations and solve for v_{max}:

$$v_{max} = \sqrt{0.8243rg}$$

Substitute numerical values and evaluate v_{max}:

$$v_{max} = \sqrt{(0.8243)(30\,\text{m})(9.81\,\text{m/s}^2)} = \boxed{15.6\,\text{m/s} = 56.1\,\text{km/h}}$$

Drag Forces

92 •

Picture the Problem We can apply Newton's 2nd law to the particle to obtain its equation of motion. Applying terminal speed conditions will yield an expression for b that we can evaluate using the given numerical values.

Apply $\sum F_y = ma_y$ to the particle:

$$mg - bv = ma_y$$

When the particle reaches its terminal speed $v = v_t$ and $a_y = 0$:

$$mg - bv_t = 0$$

Solve for b to obtain:

$$b = \frac{mg}{v_t}$$

Substitute numerical values and evaluate b:

$$b = \frac{(10^{-13}\,\text{kg})(9.81\,\text{m/s}^2)}{3\times 10^{-4}\,\text{m/s}} = \boxed{3.27\times 10^{-9}\,\text{kg/s}}$$

93 •

Picture the Problem We can apply Newton's 2nd law to the Ping-Pong ball to obtain its equation of motion. Applying terminal speed conditions will yield an expression for b that we can evaluate using the given numerical values.

Apply $\sum F_y = ma_y$ to the Ping-Pong ball:

$$mg - bv^2 = ma_y$$

When the Ping-Pong ball reaches its terminal speed $v = v_t$ and $a_y = 0$:

$$mg - bv_t^2 = 0$$

Solve for b to obtain:

$$b = \frac{mg}{v_t^2}$$

Substitute numerical values and evaluate b:

$$b = \frac{(2.3\times10^{-3}\,\text{kg})(9.81\,\text{m/s}^2)}{(9\,\text{m/s})^2} = \boxed{2.79\times10^{-4}\,\text{kg/m}}$$

***94 •**

Picture the Problem Let the upward direction be the positive y direction and apply Newton's 2nd law to the sky diver.

(*a*) Apply $\sum F_y = ma_y$ to the sky diver:

$$F_\text{d} - mg = ma_y$$

or, because $a_y = 0$,

$$F_\text{d} = mg \qquad (1)$$

Substitute numerical values and evaluate F_d:

$$F_\text{d} = (60\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{589\,\text{N}}$$

(*b*) Substitute $F_\text{d} = bv_\text{t}^2$ in equation (1) to obtain:

$$bv_\text{t}^2 = mg$$

Solve for b:

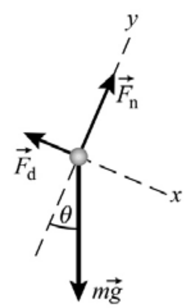
$$b = \frac{mg}{v_\text{t}^2} = \frac{F_\text{d}}{v_\text{t}^2}$$

Substitute numerical values and evaluate b:

$$b = \frac{589\,\text{N}}{(25\,\text{m/s})^2} = \boxed{0.942\,\text{kg/m}}$$

95 ••

Picture the Problem The free-body diagram shows the forces acting on the car as it descends the grade with its terminal velocity. The application of Newton's 2nd law with $a = 0$ and F_d equal to the given function will allow us to solve for the terminal velocity of the car.



Apply $\sum F_x = ma_x$ to the car:

$$mg\sin\theta - F_\text{d} = ma_x$$

or, because $v = v_\text{t}$ and $a_x = 0$,

$$mg\sin\theta - F_\text{d} = 0$$

Substitute for F_d to obtain:

$$mg\sin\theta - 100\,\text{N} - (1.2\,\text{N}\cdot\text{s}^2/\text{m}^2)v_\text{t}^2 = 0$$

Solve for v_t:

$$v_t = \sqrt{\frac{mg\sin\theta - 100\,\text{N}}{1.2\,\text{N}\cdot\text{s}^2/\text{m}^2}}$$

Substitute numerical values and evaluate v_t:

$$v_t = \sqrt{\frac{(800\,\text{kg})(9.81\,\text{m/s}^2)\sin 6° - 100\,\text{N}}{1.2\,\text{N}\cdot\text{s}^2/\text{m}^2}}$$

$$= 24.5\,\text{m/s} = \boxed{88.2\,\text{km/h}}$$

96 •••

Picture the Problem Let the upward direction be the positive *y* direction and apply Newton's 2nd law to the particle to obtain an equation from which we can find the particle's terminal speed.

(*a*) Apply $\sum F_y = ma_y$ to a pollution particle:

$$mg - 6\pi\eta r v = ma_y$$

or, because $a_y = 0$,

$$mg - 6\pi\eta r v_t = 0$$

Solve for v_t to obtain:

$$v_t = \frac{mg}{6\pi\eta r}$$

Express the mass of a sphere in terms of its volume:

$$m = \rho V = \rho\left(\frac{4\pi r^3}{3}\right)$$

Substitute for *m* to obtain:

$$v_t = \frac{2r^2\rho g}{9\eta}$$

Substitute numerical values and evaluate v_t:

$$v_t = \frac{2(10^{-5}\,\text{m})^2(2000\,\text{kg/m}^3)(9.81\,\text{m/s}^2)}{9(1.8\times10^{-5}\,\text{N}\cdot\text{s/m}^2)}$$

$$= \boxed{2.42\,\text{cm/s}}$$

(*b*) Use distance equals average speed times the fall time to find the time to fall 100 m at 2.42 cm/s:

$$t = \frac{10^4\,\text{cm}}{2.42\,\text{cm/s}} = 4.13\times10^3\,\text{s} = \boxed{1.15\,\text{h}}$$

***97 •••**

Picture the Problem The motion of the centrifuge will cause the pollution particles to migrate to the end of the test tube. We can apply Newton's 2nd law and Stokes' law to derive an expression for the terminal speed of the sedimentation particles. We can then use this terminal speed to calculate the sedimentation time. We'll use the 12 cm distance from the center of the centrifuge as the average radius of the pollution particles as they settle in the test tube. Let R represent the radius of a particle and r the radius of the particle's circular path in the centrifuge.

Express the sedimentation time in terms of the sedimentation speed v_t:

$$\Delta t_{\text{sediment}} = \frac{\Delta x}{v_t}$$

Apply $\sum F_{\text{radial}} = ma_{\text{radial}}$ to a pollution particle:

$$6\pi\eta R v_t = ma_c$$

Express the mass of the particle in terms of its radius R and density ρ:

$$m = \rho V = \tfrac{4}{3}\pi R^3 \rho$$

Express the acceleration of the pollution particles due to the motion of the centrifuge in terms of their orbital radius r and period T:

$$a_c = \frac{v^2}{r} = \frac{\left(\frac{2\pi r}{T}\right)^2}{r} = \frac{4\pi^2 r}{T^2}$$

Substitute for m and a_c and simplify to obtain:

$$6\pi\eta R v_t = \tfrac{4}{3}\pi R^3 \rho\left(\frac{4\pi^2 r}{T^2}\right) = \frac{16\pi^3 \rho r R^3}{3T^2}$$

Solve for v_t:

$$v_t = \frac{8\pi^2 \rho r R^2}{9\eta T^2}$$

Find the period T of the motion from the number of revolutions the centrifuge makes in 1 second:

$$T = \frac{1}{800\,\text{rev/min}} = 1.25\times10^{-3}\ \text{min/rev}$$
$$= 1.25\times10^{-3}\ \text{min/rev}\times 60\,\text{s/min}$$
$$= 75.0\times10^{-3}\ \text{s/rev}$$

Substitute numerical values and evaluate v_t:

$$v_t = \frac{8\pi^2\left(2000\,\text{kg/m}^3\right)(0.12\,\text{m})\left(10^{-5}\,\text{m}\right)^2}{9\left(1.8\times10^{-5}\,\text{N}\cdot\text{s/m}^2\right)\left(75\times10^{-3}\,\text{s}\right)^2}$$
$$= 2.08\,\text{m/s}$$

Find the time it takes the particles to move 8 cm as they settle in the test tube:

$$\Delta t_{\text{sediment}} = \frac{\Delta x}{v} = \frac{8\,\text{cm}}{208\,\text{cm/s}}$$
$$= \boxed{38.5\,\text{ms}}$$

In Problem 96 it was shown that the rate of fall of the particles in air is 2.42 cm/s. Find the time required to fall 8 cm in air under the influence of gravity:

$$\Delta t_{air} = \frac{\Delta x}{v} = \frac{8\,\text{cm}}{2.42\,\text{cm/s}} = \boxed{3.31\,\text{s}}$$

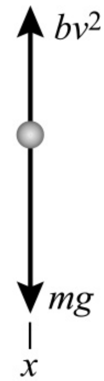
Find the ratio of the two times:

$$\Delta t_{air}/\Delta t_{sediment} \approx \boxed{100}$$

Euler's Method

98 ••

Picture the Problem The free-body diagram shows the forces acting on the baseball sometime after it has been thrown downward but before it has reached its terminal speed. In order to use Euler's method, we'll need to determine how the acceleration of the ball varies with its speed. We can do this by applying Newton's 2nd law to the ball and using its terminal speed to express the constant in the acceleration equation in terms of the ball's terminal speed. We can then use $v_{n+1} = v_n + a_n \Delta t$ to find the speed of the ball at any given time.



Apply Newton's 2nd law to the ball to obtain:

$$mg - bv^2 = m\frac{dv}{dt}$$

Solve for dv/dt to obtain:

$$\frac{dv}{dt} = g - \frac{b}{m}v^2$$

When the ball reaches its terminal speed:

$$0 = g - \frac{b}{m}v_t^2 \Rightarrow \frac{b}{m} = \frac{g}{v_t^2}$$

Substitute to obtain:

$$\frac{dv}{dt} = g\left(1 - \frac{v^2}{v_t^2}\right)$$

Express the position of the ball to obtain:

$$x_{n+1} = x_n + \frac{v_{n+1} + v_n}{2}\Delta t$$

Letting a_n be the acceleration of the ball at time t_n, express its speed when $t = t_n + 1$:

$$v_{n+1} = v_n + a_n \Delta t$$

where

$$a_n = g\left(1 - \frac{v_n^2}{v_t^2}\right)$$

and Δt is an arbitrarily small interval of time.

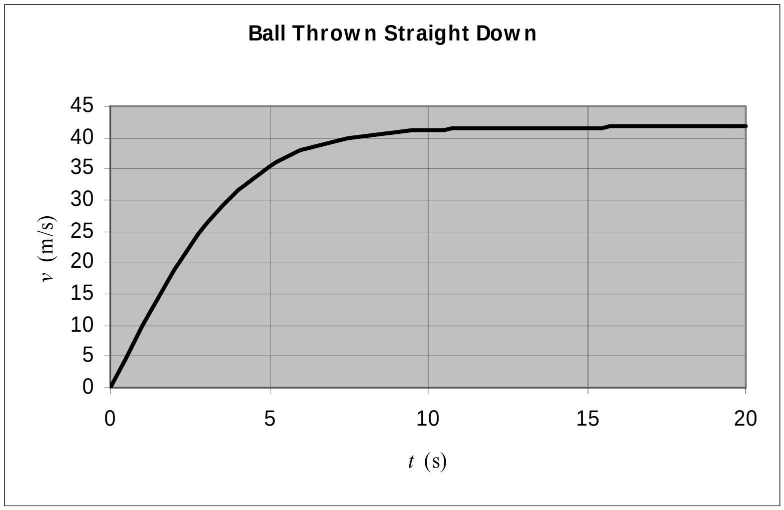
A spreadsheet solution is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
A10	B9+$B$1	$t + \Delta t$
B10	B9+0.5*(C9+C10)*$B$1	$x_{n+1} = x_n + \frac{v_{n+1} + v_n}{2}\Delta t$
C10	C9+D9*$B$1	$v_{n+1} = v_n + a_n\Delta t$
D10	$B$4*(1–C10^2/$B$5^2)	$a_n = g\left(1 - \frac{v_n^2}{v_t^2}\right)$

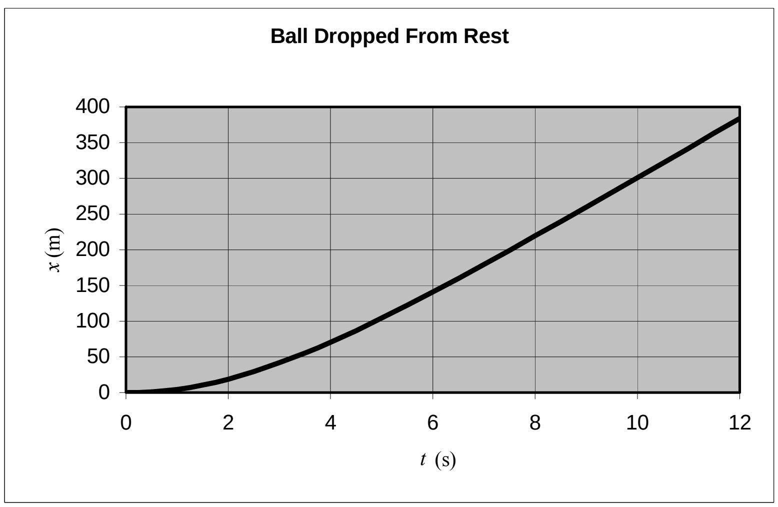
	A	B	C	D
1	Δt=	0.5	s	
2	x0=	0	m	
3	v0=	9.722	m/s	
4	a0=	9.81	m/s^2	
5	vt=	41.67	m/s	
6				
7	t	x	v	a
8	(s)	(m)	(m/s)	(m/s^2)
9	0.0	0	9.7	9.28
10	0.5	6	14.4	8.64
11	1.0	14	18.7	7.84
12	1.5	25	22.6	6.92
28	9.5	317	41.3	0.17
29	10.0	337	41.4	0.13
30	10.5	358	41.5	0.10
38	14.5	524	41.6	0.01
39	15.0	545	41.7	0.01
40	15.5	566	41.7	0.01
41	16.0	587	41.7	0.01
42	16.5	608	41.7	0.00

From the table we can see that the speed of the ball after 10 s is approximately $\boxed{41.4\,\text{m/s.}}$ We can estimate the uncertainty in this result by halving Δt and recalculating the speed of the ball at $t = 10$ s. Doing so yields $v(10\text{ s}) \approx 41.3$ m/s, a difference of about $\boxed{0.02\%.}$

The graph shows the velocity of the ball thrown straight down as a function of time.

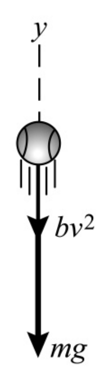


Reset Δt to 0.5 s and set $v_0 = 0$. Ninety-nine percent of 41.67 m/s is approximately 41.3 m/s. Note that the ball will reach this speed in about $\boxed{10.5\,\text{s}}$ and that the distance it travels in this time is about $\boxed{322\,\text{m.}}$ The following graph shows the distance traveled by the ball dropped from rest as a function of time.



***99** ••

Picture the Problem The free-body diagram shows the forces acting on the baseball after it has left your hand. In order to use Euler's method, we'll need to determine how the acceleration of the ball varies with its speed. We can do this by applying Newton's 2nd law to the baseball. We can then use $v_{n+1} = v_n + a_n\Delta t$ and $x_{n+1} = x_n + v_n\Delta t$ to find the speed and



position of the ball.

Apply $\sum F_y = ma_y$ to the baseball:

$$-bv|v| - mg = m\frac{dv}{dt}$$

where $|v| = v$ for the upward part of the flight of the ball and $|v| = -v$ for the downward part of the flight.

Solve for dv/dt:

$$\frac{dv}{dt} = -g - \frac{b}{m}v|v|$$

Under terminal speed conditions ($|v| = -v_t$):

$$0 = -g + \frac{b}{m}v_t^2$$

and

$$\frac{b}{m} = \frac{g}{v_t^2}$$

Substitute to obtain:

$$\frac{dv}{dt} = -g - \frac{g}{v_t^2}v|v| = -g\left(1 + \frac{v|v|}{v_t^2}\right)$$

Letting a_n be the acceleration of the ball at time t_n, express its position and speed when $t = t_n + 1$:

$$y_{n+1} = y_n + \tfrac{1}{2}(v_n + v_{n-1})\Delta t$$

and

$$v_{n+1} = v_n + a_n\Delta t$$

where

$$a_n = -g\left(1 + \frac{v_n|v_n|}{v_t^2}\right)$$

and Δt is an arbitrarily small interval of time.

A spreadsheet solution is shown below. The formulas used to calculate the quantities in the columns are as follows:

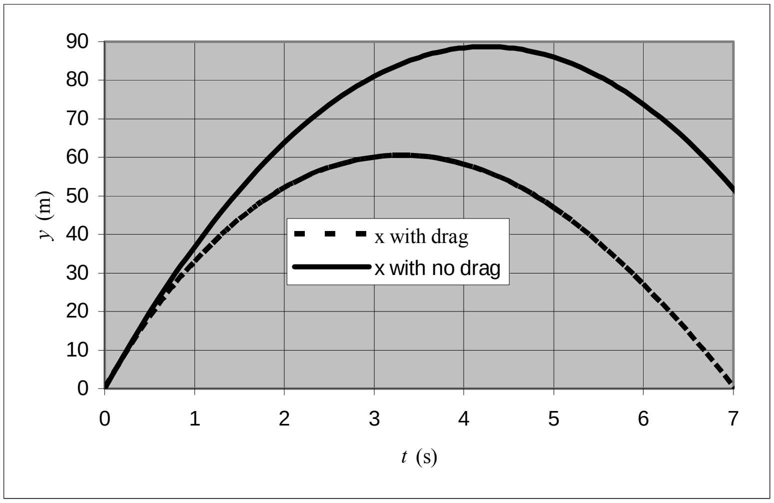
80				7.0	–29.37	0.49	51.80
81				7.1	–29.87	–2.47	49.06

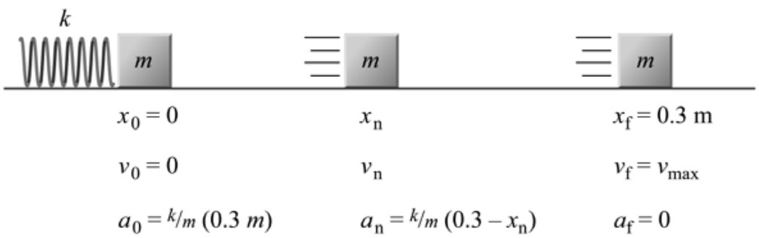
From the table we can see that, after 3.5 s, the ball reaches a height of about $\boxed{60.4\,\text{m.}}$ It reaches its peak a little earlier–at about $\boxed{3.3\,\text{s,}}$ and its height at $t = 3.3$ s is $\boxed{60.6\,\text{m.}}$ The ball hits the ground at about $t = \boxed{7\,\text{s}}$ –so it spends a little longer coming down than going up.

The solid curve on the following graph shows $y(t)$ when there is no drag on the baseball and the dotted curve shows $y(t)$ under the conditions modeled in this problem.



100 ••

Picture the Problem The pictorial representation shows the block in its initial position against the compressed spring, later as the spring accelerates it to the right, and finally when it has reached its maximum speed at $x_f = 0$. In order to use Euler's method, we'll need to determine how the acceleration of the block varies with its position. We can do this by applying Newton's 2nd law to the box. We can then use $v_{n+1} = v_n + a_n\Delta t$ and $x_{n+1} = x_n + v_n\Delta t$ to find the speed and position of the block.



Apply $\sum F_x = ma_x$ to the block:

$$k(0.3\,\text{m} - x_n) = ma_n$$

Solve for a_n:

$$a_n = \frac{k}{m}(0.3\,\text{m} - x_n)$$

Express the position and speed of the block when $t = t_n + 1$:

$$x_{n+1} = x_n + v_n\Delta t$$

and

$$v_{n+1} = v_n + a_n\Delta t$$

where

$$a_n = \frac{k}{m}(0.3\,\text{m} - x_n)$$

and Δt is an arbitrarily small interval of time.

A spreadsheet solution is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
A10	A9+$B$1	$t + \Delta t$
B10	B9+C10*$B$1	$x_n + v_n \Delta t$
C10	C9+D9*$B$1	$v_n + a_n \Delta t$
D10	($B$4/$B$5)*(0.3–B10)	$\frac{k}{m}(0.3 - x_n)$

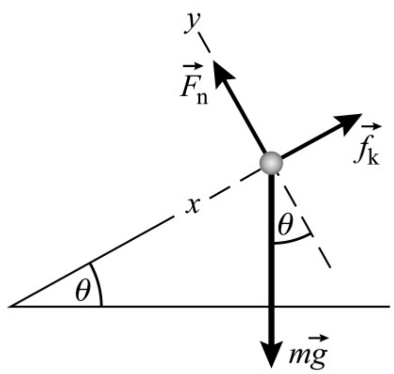
	A	B	C	D
1	Δt=	0.005	s	
2	x0=	0	m	
3	v0=	0	m/s	
4	k =	50	N/m	
5	m =	0.8	kg	
6				
7	t	x	v	a
8	(s)	(m)	(m/s)	(m/s^2)
9	0.000	0.00	0.00	18.75
10	0.005	0.00	0.09	18.72
11	0.010	0.00	0.19	18.69
12	0.015	0.00	0.28	18.63
45	0.180	0.25	2.41	2.85
46	0.185	0.27	2.42	2.10
47	0.190	0.28	2.43	1.34
48	0.195	0.29	2.44	0.58
49	0.200	0.30	2.44	–0.19

From the table we can see that it took about $\boxed{0.200\,\text{s}}$ for the spring to push the block 30 cm and that it was traveling about $\boxed{2.44\,\text{m/s}}$ at that time. We can estimate the uncertainty in this result by halving Δt and recalculating the speed of the ball at t = 10 s. Doing so yields v(0.200 s) ≈ 2.41 m/s, a difference of about $\boxed{1.2\%.}$

General Problems

101 •

Picture the Problem The forces that act on the block as it slides down the incline are shown on the free-body diagram to the right. The acceleration of the block can be determined from the distance-and-time information given in the problem. The application of Newton's 2nd law to the block will lead to an expression for the coefficient of kinetic friction as a function of the block's acceleration and the angle of the incline.



Apply $\sum\vec{F} = m\vec{a}$ to the block:

$$\Sigma F_x = mg\sin\theta - f_k = ma$$
and
$$\Sigma F_y = F_n - mg = 0$$

Set $f_k = \mu_k F_n$, F_n between the two equations, and solve for μ_k:

$$\mu_k = \frac{g\sin\theta - a}{g\cos\theta}$$

Using a constant-acceleration equation, relate the distance the block slides to its sliding time:

$$\Delta x = v_0\Delta t + \tfrac{1}{2}a(\Delta t)^2 \text{ where } v_0 = 0$$

Solve for a:

$$a = \frac{2\Delta x}{(\Delta t)^2}$$

Substitute numerical values and evaluate a:

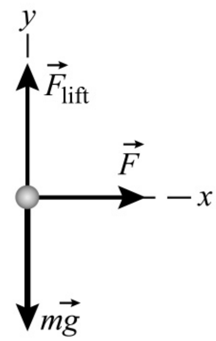
$$a = \frac{2(2.4\,\text{m})}{(5.2\,\text{s})^2} = 0.1775\,\text{m/s}^2$$

Find μ_k for $a = 0.1775$ m/s^2 and $\theta = 28°$:

$$\mu_k = \frac{(9.81\,\text{m/s}^2)\sin 28° - 0.1775\,\text{m/s}^2}{(9.81\,\text{m/s}^2)\cos 28°} = \boxed{0.511}$$

102 •

Picture the Problem The free-body diagram shows the forces acting on the model airplane. The speed of the plane can be calculated from the data concerning the radius of its path and the time it takes to make one revolution. The application of Newton's 2nd law will give us the tension F in the string.



(*a*) Express the speed of the airplane in terms of the circumference of the circle in which it is flying and its period:

$$v = \frac{2\pi r}{T}$$

Substitute numerical values and evaluate v:

$$v = \frac{2\pi(5.7\,\text{m})}{\frac{4}{1.2}\,\text{s}} = \boxed{10.7\,\text{m/s}}$$

(*b*) Apply $\sum F_x = ma_x$ to the model airplane:

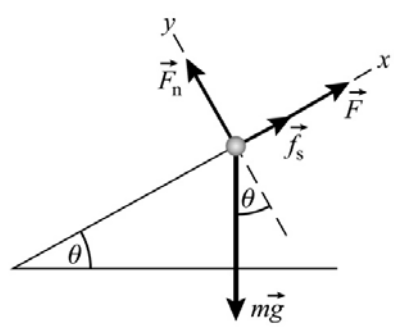
$$F = m\frac{v^2}{r}$$

Substitute numerical values and evaluate F:

$$F = (0.4\,\text{kg})\frac{(10.7\,\text{m/s})^2}{5.7\,\text{m}} = \boxed{8.03\,\text{N}}$$

***103** ••

Picture the Problem The free-body diagram shows the forces acting on the box. If the student is pushing with a force of 200 N and the box is on the verge of moving, the static friction force must be at its maximum value. In part (*b*), the motion is impending up the incline; therefore the direction of $f_{s,max}$ is down the incline.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the box:

$$\sum F_x = f_s + F - mg\sin\theta = 0$$

and

$$\sum F_y = F_n - mg\cos\theta = 0$$

Substitute $f_s = f_{s,max} = \mu_s F_n$, eliminate F_n between the two equations, and solve for μ_s:

$$\mu_s = \tan\theta - \frac{F}{mg\cos\theta}$$

Substitute numerical values and evaluate μ_s:

$$\mu_s = \tan 30° - \frac{200\,\text{N}}{(800\,\text{N})\cos 30°} = \boxed{0.289}$$

(*b*) Find $f_{s,max}$ from the *x*-direction force equation:

$$f_{s,max} = mg\sin\theta - F$$

Substitute numerical values and evaluate $f_{s,max}$:

$$f_{s,max} = (800\,\text{N})\sin 30° - 200\,\text{N} = 200\,\text{N}$$

If the block is on the verge of sliding up the incline, $f_{s,max}$ must act down the incline. The *x*-direction force equation becomes:

$$-f_{s,max} + F - mg\sin\theta = 0$$

Solve the *x*-direction force equation for *F*:

$$F = mg\sin\theta + f_{s,max}$$

Substitute numerical values and evaluate *F*:

$$F = (800\,\text{N})\sin 30° + 200\,\text{N} = \boxed{600\,\text{N}}$$

104 •

Picture the Problem The path of the particle is a circle if *r* is a constant. Once we have shown that it is, we can calculate its value from its components. The direction of the particle's motion can be determined by examining two positions of the particle at times that are close to each other.

(*a*) and (*b*) Express the magnitude of $\vec{r}$ in terms of its components:

$$r = \sqrt{r_x^2 + r_y^2}$$

Evaluate *r* with $r_x = -10$ m cos ωt and $r_y = 10$ m sinωt:

$$r = \sqrt{[(-10\,\text{m})\cos\omega t]^2 + [(10\,\text{m})\sin\omega t]^2} = \sqrt{100(\cos^2\omega t + \sin^2\omega t)}\,\text{m} = \boxed{10.0\,\text{m}}$$

(*c*) Evaluate r_x and r_y at $t = 0$ s:

$$r_x = -(10\,\text{m})\cos 0° = -10\,\text{m}$$
$$r_y = (10\,\text{m})\sin 0° = 0$$

Evaluate r_x and r_y at $t = \Delta t$, where Δt is small:

$$r_x = -(10\,\text{m})\cos\omega\Delta t \approx -(10\,\text{m})\cos 0° = -10\,\text{m}$$
$$r_y = (10\,\text{m})\sin\omega\Delta t = \Delta y \text{ where } \Delta y \text{ is positive}$$

and $\boxed{\text{the motion is clockwise}}$

(*d*) Differentiate $\vec{r}$ with respect to time to obtain $\vec{v}$:

$$\vec{v} = d\vec{r}/dt = [(10\omega\sin\omega t)m]\,\hat{i} + [(10\omega\cos\omega t)m]\,\hat{j}$$

Use the components of $\vec{v}$ to find its speed:

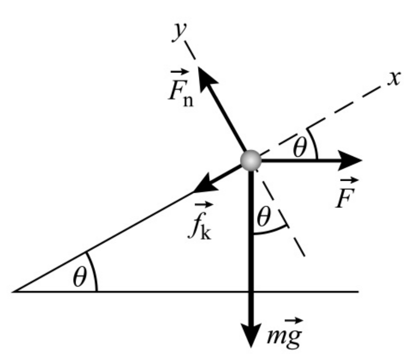
$$v = \sqrt{v_x^2 + v_y^2} = \sqrt{[(10\omega\sin\omega t)\text{m}]^2 + [(10\omega\cos\omega t)\text{m}]^2} = (10\,\text{m})\omega = (10\,\text{m})(2\,\text{s}^{-1}) = \boxed{20.0\,\text{m/s}}$$

(*e*) Relate the period of the particle's motion to the radius of its path and its speed:

$$T = \frac{2\pi r}{v} = \frac{2\pi(10\,\text{m})}{20\,\text{m/s}} = \boxed{\pi\,\text{s}}$$

105 ••

Picture the Problem The free-body diagram shows the forces acting on the crate of books. The kinetic friction force opposes the motion of the crate up the incline. Because the crate is moving at constant speed in a straight line, its acceleration is zero. We can determine F by applying Newton's 2nd law to the crate, substituting for f_k, eliminating the normal force, and solving for the required force.



Apply $\sum\vec{F} = m\vec{a}$ to the crate, with both a_x and a_y equal to zero, to the crate:

$$\sum F_x = F\cos\theta - f_k - mg\sin\theta = 0$$

and

$$\sum F_y = F_n - F\sin\theta - mg\cos\theta = 0$$

Substitute $\mu_s F_n$ for f_k and eliminate F_n to obtain:

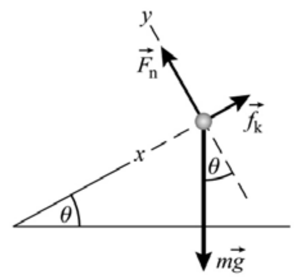
$$F = \frac{mg(\sin\theta + \mu_k \cos\theta)}{\cos\theta - \mu_k \sin\theta}$$

Substitute numerical values and evaluate F:

$$F = \frac{(100\,\text{kg})(9.81\,\text{m/s}^2)(\sin 30° + (0.5)\cos 30°)}{\cos 30° - (0.5)\sin 30°} = \boxed{1.49\,\text{kN}}$$

106 ••

Picture the Problem The free-body diagram shows the forces acting on the object as it slides down the inclined plane. We can calculate its speed at the bottom of the incline from its acceleration and displacement and find its acceleration from Newton's 2nd law.



Using a constant-acceleration equation, relate the initial and final velocities of the object to its acceleration and displacement: solve for the final velocity:

$$v^2 = v_0^2 + 2a\Delta x$$

Because $v_0 = 0$, $v = \sqrt{2a\Delta x}$ (1)

Apply $\sum \vec{F} = m\vec{a}$ to the sliding object:

$$\sum F_x = -f_k + mg\sin\theta = ma$$

and

$$\sum F_y = F_n - mg\cos\theta = 0$$

Solve the y equation for F_n and using $f_k = \mu_k F_n$, eliminate both F_n and f_k from the x equation and solve for a:

$$a = g(\sin\theta - \mu_k \cos\theta) \quad (2)$$

Substitute equation (2) in equation (1) and solve for v:

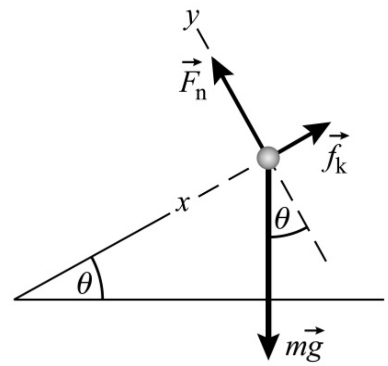
$$v = \sqrt{2g(\sin\theta - \mu_k\cos\theta)\Delta x}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{2(9.81\,\text{m/s}^2)(\sin 30° - (0.35)\cos 30°)(72\,\text{m})} = 16.7\,\text{m/s} \text{ and } \boxed{(d)\text{ is correct.}}$$

***107** ••

Picture the Problem The free-body diagram shows the forces acting on the brick as it slides down the inclined plane. We'll apply Newton's 2nd law to the brick when it is sliding down the incline with constant speed to derive an expression for μ_k in terms of θ_0. We'll apply Newton's 2nd law a second time for $\theta = \theta_1$ and solve the equations simultaneously to obtain an expression for a as a function of θ_0 and θ_1.



Apply $\sum \vec{F} = m\vec{a}$ to the brick when it is sliding with constant speed:

$$\sum F_x = -f_k + mg\sin\theta_0 = 0$$

and

$$\sum F_y = F_n - mg\cos\theta_0 = 0$$

Solve the y equation for F_n and using $f_k = \mu_k F_n$, eliminate both F_n and f_k from the x equation and solve for μ_k:

$$\mu_k = \tan\theta_0$$

Apply $\sum \vec{F} = m\vec{a}$ to the brick when $\theta = \theta_1$:

$$\sum F_x = -f_k + mg\sin\theta_1 = ma$$

and

$$\sum F_y = F_n - mg\cos\theta_1 = 0$$

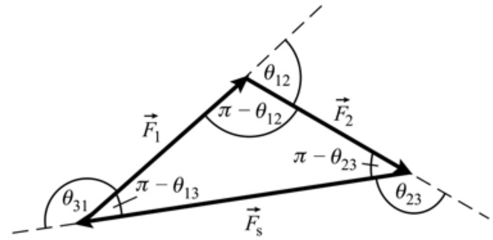
Solve the y equation for F_n, use $f_k = \mu_k F_n$ to eliminate both F_n and f_k from the x equation, and use the expression for μ_k obtained above to obtain:

$$\boxed{a = g(\sin\theta_1 - \tan\theta_0\cos\theta_1)}$$

108 ••

Picture the Problem The fact that the object is in static equilibrium under the influence of the three forces means that $\vec{F}_1 + \vec{F}_2 + \vec{F}_3 = 0$. Drawing the corresponding force triangle will allow us to relate the forces to the angles between them through the law of sines and the law of cosines.

(*a*) Using the fact that the object is in static equilibrium, redraw the force diagram connecting the forces head-to-tail:



Apply the law of sines to the triangle:

$$\frac{F_1}{\sin(\pi-\theta_{23})}=\frac{F_2}{\sin(\pi-\theta_{13})}=\frac{F_3}{\sin(\pi-\theta_{12})}$$

Use the trigonometric identity $\sin(\pi-\alpha)=\sin\alpha$ to obtain:

$$\boxed{\frac{F_1}{\sin\theta_{23}}=\frac{F_2}{\sin\theta_{13}}=\frac{F_3}{\sin\theta_{12}}}$$

(*b*) Apply the law of cosines to the triangle:

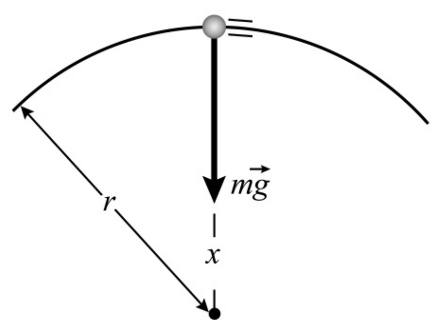
$$F_1^2=F_2^2+F_3^2-2F_2F_3\cos(\pi-\theta_{23})$$

Use the trigonometric identity $\cos(\pi-\alpha)=-\cos\alpha$ to obtain:

$$\boxed{F_1^2=F_2^2+F_3^2+2F_2F_3\cos\theta_{23}}$$

109 ••

Picture the Problem We can calculate the acceleration of the passenger from his/her speed that, in turn, is a function of the period of the motion. To determine the longest period of the motion, we focus our attention on the situation at the very top of the ride when the seat belt is exerting no force on the rider. We can use Newton's 2nd law to relate the period of the motion to the acceleration and speed of the rider.



(*a*) Because the motion is at constant speed, the acceleration is entirely radial and is given by:

$$a_c=\frac{v^2}{r}$$

Express the speed of the motion of the ride as a function of the radius of the circle and the period of its motion:

$$v=\frac{2\pi r}{T}$$

Substitute in the expression for a_c to obtain:

$$a_c = \frac{4\pi^2 r}{T^2}$$

Substitute numerical values and evaluate a_c:

$$a_c = \frac{4\pi^2(5\,\text{m})}{(2\,\text{s})^2} = \boxed{49.3\,\text{m/s}^2}$$

(*b*) Apply $\sum \vec{F} = m\vec{a}$ to the passenger when he/she is at the top of the circular path and solve for a_c:

$$\sum F_r = mg = ma_c$$

and

$a_c = g$

Relate the acceleration of the motion to its radius and speed and solve for v:

$$g = \frac{v^2}{r} \Rightarrow v = \sqrt{gr}$$

Express the period of the motion as a function of the radius of the circle and the speed of the passenger and solve for T_m:

$$T_m = \frac{2\pi r}{v} = 2\pi\sqrt{\frac{r}{g}}$$

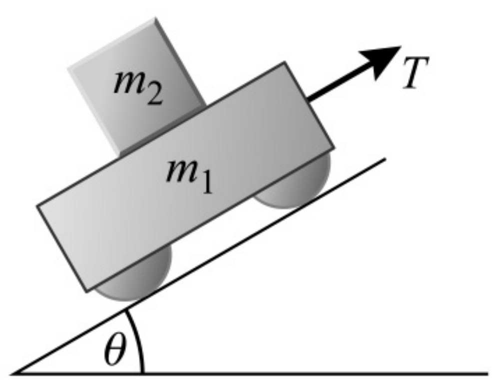
Substitute numerical values and evaluate T_m:

$$T_m = 2\pi\sqrt{\frac{5\,\text{m}}{9.81\,\text{m/s}^2}} = \boxed{4.49\,\text{s}}$$

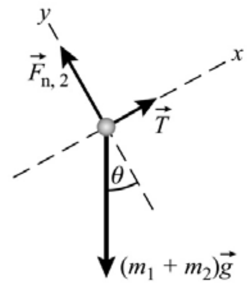
Remarks: The rider is "weightless" under the conditions described in part (*b*).

***110** ••

Picture the Problem The pictorial representation to the right shows the cart and its load on the inclined plane. The load will not slip provided its maximum acceleration is not exceeded. We can find that maximum acceleration by applying Newton's 2nd law to the load. We can then apply Newton's 2nd law to the cart-plus-load system to determine the tension in the rope when the system is experiencing its maximum acceleration.



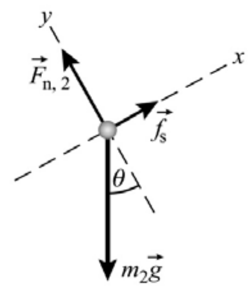
Draw the free-body diagram for the cart and its load:



Apply $\sum F_x = ma_x$ to the cart plus its load:

$$T - (m_1 + m_2)g\sin\theta = (m_1 + m_2)a_{\text{max}} \quad (1)$$

Draw the free-body diagram for the load of mass m_2 on top of the cart:



Apply $\sum \vec{F} = m\vec{a}$ to the load on top of the cart:

$$\sum F_x = f_{\text{s,max}} - m_2 g\sin\theta = m_2 a_{\text{max}}$$

and

$$\sum F_y = F_{\text{n,2}} - m_2 g\cos\theta = 0$$

Using $f_{\text{s,max}} = \mu_s F_{\text{n,2}}$, eliminate $F_{\text{n,2}}$ between the two equations and solve for the maximum acceleration of the load:

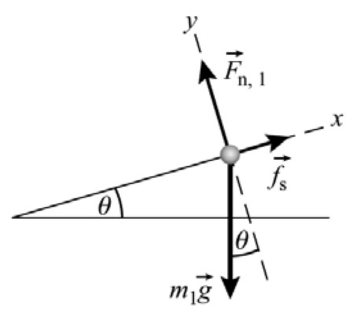
$$a_{\text{max}} = g(\mu_s\cos\theta - \sin\theta) \quad (2)$$

Substitute equation (2) in equation (1) and solve for T:

$$T = \boxed{(m_1 + m_2)g\mu_s\cos\theta}$$

111 ••

Picture the Problem The free-body diagram for the sled while it is held stationary by the static friction force is shown to the right. We can solve this problem by repeatedly applying Newton's 2nd law under the conditions specified in each part of the problem.



(*a*) Apply $\sum F_y = ma_y$ to the sled:

$$F_{n,1} - m_1 g\cos\theta = 0$$

Solve for $F_{n,1}$:

$$F_{n,1} = m_1 g\cos\theta$$

Substitute numerical values and evaluate $F_{n,1}$:

$$F_{n,1} = (200\,\text{N})\cos 15° = \boxed{193\,\text{N}}$$

(*b*) Apply $\sum F_x = ma_x$ to the sled:

$$f_s - m_1 g\sin\theta = 0$$

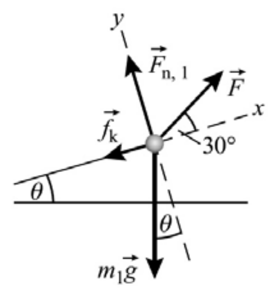
Solve for f_s:

$$f_s = m_1 g\sin\theta$$

Substitute numerical values and evaluate f_s:

$$f_s = (200\,\text{N})\sin 15° = \boxed{51.8\,\text{N}}$$

(*c*) Draw the free-body diagram for the sled when the child is pulling on the rope:



Apply $\sum \vec{F} = m\vec{a}$ to the sled to determine whether it moves:

$$\sum F_x = F_{net} = F\cos 30° - m_1 g\sin\theta - f_{s,max}$$

and

$$\sum F_y = F_{n,1} + F\sin 30° - m_1 g\cos\theta = 0$$

Solve the y-direction equation for $F_{n,1}$:

$$F_{n,1} = -F\sin 30° + m_1 g\cos\theta$$

Substitute numerical values and evaluate $F_{n,1}$:

$$F_{n,1} = -(100\,\text{N})\sin 30° + (200\,\text{N})\cos 15° = 143\,\text{N}$$

Express $f_{s,max}$:

$$f_{s,max} = \mu_s F_{n,1} = (0.5)(143\text{ N}) = 71.5\text{ N}$$

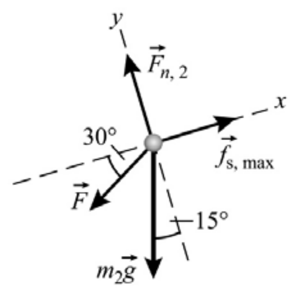
Use the x-direction force equation to evaluate F_{net}:

$$F_{net} = (100\text{ N})\cos 30° - (200\text{ N})\sin 15° - 71.5\text{ N} = -36.7\text{ N}$$

Because the net force is negative, the sled does not move: $\boxed{f_\text{k} \text{ is undetermined}}$

(*d*) Because the sled does not move: $\boxed{\mu_\text{k} \text{ is undetermined}}$

(*e*) Draw the FBD for the child:



Express the net force F_c exerted on the child by the incline:

$$F_\text{c} = \sqrt{F_\text{n2}^2 + f_\text{s,max}^2} \quad (1)$$

Noting that the child is stationary, apply $\sum \vec{F} = m\vec{a}$ to the child:

$$\sum F_x = f_\text{s,max} - F\cos 30° - m_2 g \sin 15° = 0$$

and

$$\sum F_y = F_\text{n2} - m_2 g \sin 15° - F \sin 30° = 0$$

Solve the x equation for $f_{s,max}$ and the y equation for F_n2:

$$f_\text{s,max} = F\cos 30° + m_2 g \sin 15°$$

and

$$F_\text{n2} = m_2 g \sin 15° + F \sin 30°$$

Substitute numerical values and evaluate F_x and F_n2:

$$f_\text{s,max} = (500\,\text{N})\cos 30° + (100\,\text{N})\sin 15° = 459\,\text{N}$$

and

$$F_\text{n2} = (100\,\text{N})\sin 15° + (500\,\text{N})\sin 30° = 276\,\text{N}$$

Substitute numerical values in equation (1) and evaluate F:

$$F_\text{c} = \sqrt{(276\,\text{N})^2 + (459\,\text{N})^2} = \boxed{536\,\text{N}}$$

112 •

Picture the Problem Let *v* represent the speed of rotation of the station, and *r* the distance from the center of the station. Because the O'Neill colony is, presumably, in deep space, the only acceleration one would experience in it would be that due to its rotation.

(*a*) Express the acceleration of anyone who is standing inside the station:

$a = v^2/r$

This acceleration is directed toward the axis of rotation. If someone inside the station drops an apple, the apple will not have any forces acting on it once released, but will move along a straight line at constant speed. However, from the point of view of our observer inside the station, if he views himself as unmoving, the apple is perceived to have an acceleration of mv^2/r directed away from the axis of rotation (a "centrifugal" force).

(*b*) Each deck must rotate the central axis with the same period *T*. Relate the speed of a person on a particular deck to his/her distance *r* from the center:

$$v = \frac{2\pi r}{T}$$

Express the "acceleration of gravity" perceived by someone a distance *r* from the center:

$$\frac{v^2}{r} = \frac{4\pi^2 r}{T^2}$$

$$\boxed{\text{i.e., the "acceleration due to gravity" decreases as } r \text{ decreases.}}$$

(*c*) Relate the desired acceleration to the radius of Babylon 5 and its period:

$$a = \frac{4\pi^2 r}{T^2}$$

Solve for *T*:

$$T = \sqrt{\frac{4\pi^2 r}{a}}$$

Substitute numerical values and evaluate *T*:

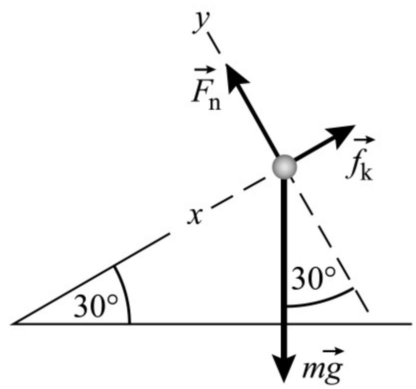
$$T = \sqrt{\frac{4\pi^2\left(0.3\,\text{mi}\times\frac{1.609\,\text{km}}{\text{mi}}\right)}{9.8\,\text{m/s}^2}} = 44.1\,\text{s} = 0.735\,\text{min}$$

Take the reciprocal of this time to find the number of revolutions per minute Babylon 5 has to make in order to provide this "earth-like" acceleration:

$$T^{-1} = \boxed{1.36\,\text{rev/min}}$$

113 ••

Picture the Problem The free-body diagram shows the forces acting on the child as she slides down the incline. We'll first use Newton's 2nd law to derive an expression for μ_k in terms of her acceleration and then use Newton's 2nd law to find her acceleration when riding the frictionless cart. Using a constant-acceleration equation, we'll relate these two accelerations to her descent times and solve for her acceleration when sliding. Finally, we can use this acceleration in the expression for μ_k.



Apply $\sum \vec{F} = m\vec{a}$ to the child as she slides down the incline:

$$\sum F_x = mg\sin 30° - f_k = ma_1$$

and

$$\sum F_y = F_n - mg\cos 30° = 0$$

Using $f_k = \mu_k F_n$, eliminate f_k and F_n between the two equations and solve for μ_k:

$$\mu_k = \tan 30° - \frac{a_1}{g\cos 30°} \qquad (1)$$

Apply $\sum F_x = ma_x$ to the child as she rides the frictionless cart down the incline and solve for her acceleration a_2:

$$mg\sin 30° = ma_2$$

and

$$a_2 = g\sin 30° = 4.91\,\text{m/s}^2$$

Letting s represent the distance she slides down the incline, use a constant-acceleration equation to relate her sliding times to her accelerations and distance traveled down the slide :

$$s = v_0 t_1 + \tfrac{1}{2}a_1 t_1^2 \text{ where } v_0 = 0$$

and

$$s = v_0 t_2 + \tfrac{1}{2}a_2 t_2^2 \text{ where } v_0 = 0$$

Equate these expressions, substitute $t_2 = \frac{1}{2}t_1$ and solve for a_1:

$$a_1 = \tfrac{1}{4}a_2 = \tfrac{1}{4}g\sin 30° = 1.23\,\text{m/s}^2$$

Evaluate equation (1) with $a_1 = 1.23\ \text{m/s}^2$:

$$\mu_k = \tan 30° - \frac{1.23\ \text{m/s}^2}{(9.81\ \text{m/s}^2)\cos 30°} = \boxed{0.433}$$

***114 ••**

Picture the Problem The path of the particle is a circle if *r* is a constant. Once we have shown that it is, we can calculate its value from its components and determine the particle's velocity and acceleration by differentiation. The direction of the net force acting on the particle can be determined from the direction of its acceleration.

(*a*) Express the magnitude of $\vec{r}$ in terms of its components:

$$r = \sqrt{r_x^2 + r_y^2}$$

Evaluate *r* with $r_x = R\sin\omega t$ and $r_y = R\cos\omega t$:

$$r = \sqrt{[R\sin\omega t]^2 + [R\cos\omega t]^2} = \sqrt{R^2(\sin^2\omega t + \cos^2\omega t)} = R = 4.0\ \text{m}$$

$$\boxed{\therefore \text{the path of the particle is a circle centered at the origin.}}$$

(*b*) Differentiate $\vec{r}$ with respect to time to obtain $\vec{v}$:

$$\vec{v} = d\vec{r}/dt = [R\omega\cos\omega t]\,\hat{i} + [-R\omega\sin\omega t]\,\hat{j} = \boxed{[(8\pi\cos 2\pi t)\text{m/s}]\,\hat{i} - [(8\pi\sin 2\pi t)\text{m/s}]\,\hat{j}}$$

Express the ratio $\dfrac{v_x}{v_y}$:

$$\frac{v_x}{v_y} = \frac{8\pi\cos\omega t}{-8\pi\sin\omega t} = -\cot\omega t$$

Express the ratio $-\dfrac{y}{x}$:

$$-\frac{y}{x} = -\frac{R\cos\omega t}{R\sin\omega t} = -\cot\omega t$$

$$\therefore \boxed{\frac{v_x}{v_y} = -\frac{y}{x}}$$

(*c*) Differentiate $\vec{v}$ with respect to time to obtain $\vec{a}$:

$$\vec{a} = d\vec{v}/dt = \boxed{[(-16\pi^2\text{m/s}^2)\sin\omega t]\,\hat{i} + [(-16\pi^2\text{m/s}^2)\cos\omega t]\,\hat{j}}$$

Factor $-4\pi^2/\text{s}^2$ from $\vec{a}$ to obtain:

$$\vec{a} = (-4\pi^2/\text{s}^2)\left[(4\sin\omega t)\hat{i} + (4\cos\omega t)\hat{j}\right]$$
$$= \boxed{(-4\pi^2/\text{s}^2)\vec{r}}$$

Because $\vec{a}$ is in the opposite direction from $\vec{r}$, it is directed toward the center of the circle in which the particle is traveling.

Find the ratio $\dfrac{v^2}{r}$:

$$\frac{v^2}{r} = \frac{(8\pi\ \text{m/s})^2}{4\ \text{m}} = \boxed{16\pi^2\ \text{m/s}^2 = a}$$

(*d*) Apply $\sum\vec{F} = m\vec{a}$ to the particle:

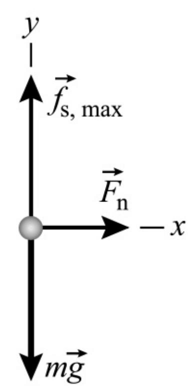
$$F_{\text{net}} = ma = (0.8\ \text{kg})(16\pi^2\ \text{m/s}^2)$$
$$= \boxed{12.8\pi^2\ \text{N}}$$

Because the direction of $\vec{F}_{\text{net}}$ is the same as that of $\vec{a}$:

$\boxed{\vec{F}_{\text{net}}\ \text{is toward the center of the circle.}}$

115 ••

Picture the Problem The free-body diagram showing the forces acting on a rider being held in place by the maximum static friction force is shown to the right. The application of Newton's 2nd law and the definition of the maximum static friction force will be used to determine the period T of the motion. The reciprocal of the period will give us the minimum number of revolutions required per unit time to hold the riders in place.



Apply $\sum\vec{F} = m\vec{a}$ to the riders while they are held in place by friction:

$$\sum F_x = F_{\text{n}} = m\frac{v^2}{r}$$

and

$$\sum F_y = f_{\text{s,max}} - mg = 0$$

Using $f_{\text{s,max}} = \mu_{\text{s}}F_{\text{n}}$ and $v = \dfrac{2\pi r}{T}$, eliminate F_{n} between the force equations and solve for the period of the motion:

$$T = 2\pi\sqrt{\frac{\mu_{\text{s}}r}{g}}$$

Substitute numerical values and evaluate T:

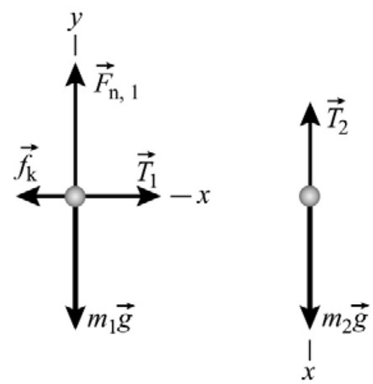
$$T = 2\pi\sqrt{\frac{(0.4)(4\,\text{m})}{9.81\,\text{m/s}^2}} = 2.54\,\text{s} = 0.00423\,\text{min}$$

The number of revolutions per minute is the reciprocal of the period in minutes:

$$\boxed{23.6\,\text{rev/min}}$$

116 ••

Picture the Problem The free-body diagrams to the right show the forces acting on the blocks whose masses are m_1 and m_2. The application of Newton's 2nd law and the use of a constant-acceleration equation will allow us to find a relationship between the coefficient of kinetic friction and m_1. The repetition of this procedure with the additional object on top of the object whose mass is m_1 will lead us to a second equation that, when solved simultaneously with the former equation, leads to a quadratic equation in m_1. Finally, its solution will allow us to substitute in an expression for μ_k and determine its value.



Using a constant-acceleration equation, relate the displacement of the system in its first configuration as a function of its acceleration and fall time:

$$\Delta x = v_0\Delta t + \tfrac{1}{2}a_1(\Delta t)^2$$

or, because $v_0 = 0$,

$$\Delta x = \tfrac{1}{2}a_1(\Delta t)^2$$

Solve for a_1:

$$a_1 = \frac{2\Delta x}{(\Delta t)^2}$$

Substitute numerical values and evaluate a_1:

$$a_1 = \frac{2(1.5\,\text{m})}{(0.82\,\text{s})^2} = 4.46\,\text{m/s}^2$$

Apply $\sum F_x = ma_x$ to the object whose mass is m_2 and solve for T_1:

$$m_2g - T_1 = m_2a_1$$

and

$$T_1 = m_2(g - a)$$

Substitute numerical values and evaluate T_1:

$$T_1 = (2.5\,\text{kg})(9.81\,\text{m/s}^2 - 4.46\,\text{m/s}^2) = 13.375\,\text{N}$$

Apply $\sum \vec{F} = m\vec{a}$ to the object whose mass is m_1:

$$\sum F_x = T_1 - f_k = m_1 a_1$$

and

$$\sum F_y = F_{n,1} - m_1 g = 0$$

Using $f_k = \mu_k F_n$, eliminate F_n between the two equations to obtain:

$$T_1 - \mu_k m_1 g = m_1 a_1 \qquad (1)$$

Find the acceleration a_2 for the second run:

$$a_2 = \frac{2\Delta x}{(\Delta t)^2} = \frac{2(1.5\,\text{m})}{(1.3\,\text{s})^2} = 1.775\,\text{m/s}^2$$

Evaluate T_2:

$$T_2 = m_2(g - a) = (2.5\,\text{kg})(9.81\,\text{m/s}^2 - 1.775\,\text{m/s}^2) = 20.1\,\text{N}$$

Apply $\sum F_x = ma_x$ to the 1.2-kg object in place:

$$T_2 - \mu_k(m_1 + 1.2\,\text{kg})g = (m_1 + 1.2\,\text{kg})a_2 \qquad (2)$$

Solve equation (1) for μ_k:

$$\mu_k = \frac{T_1 - m_1 a_1}{m_1 g} \qquad (3)$$

Substitute for μ_k in equation (2) and simplify to obtain the quadratic equation in m_1:

$$2.685 m_1^2 + 9.947 m_1 - 16.05 = 0$$

Solve the quadratic equation to obtain:

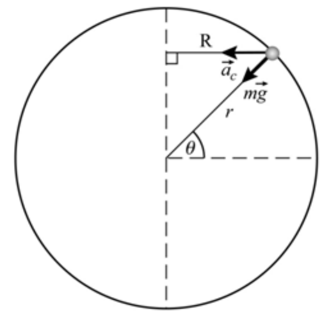
$$m_1 = (-1.85 \pm 3.07)\text{kg} \Rightarrow m_1 = \boxed{1.22\,\text{kg}}$$

Substitute numerical values in equation (3) and evaluate μ_k:

$$\mu_k = \frac{13.375\,\text{N} - (1.22\,\text{kg})(4.66\,\text{m/s}^2)}{(1.22\,\text{kg})(9.81\,\text{m/s}^2)} = \boxed{0.643}$$

***117** •••

Picture the Problem The diagram shows a point on the surface of the earth at latitude θ. The distance R to the axis of rotation is given by $R = r\cos\theta$. We can use the definition of centripetal acceleration to express the centripetal acceleration of a point on the surface of the earth due to the rotation of the earth.



(*a*) Referring to the figure, express a_c for a point on the surface of the earth at latitude θ:

$$a_c = \frac{v^2}{R} \text{ where } R = r\cos\theta$$

Express the speed of the point due to the rotation of the earth:

$$v = \frac{2\pi R}{T}$$

where T is the time for one revolution.

Substitute for v in the expression for a_c and simplify to obtain:

$$a_c = \frac{4\pi^2 r\cos\theta}{T^2}$$

Substitute numerical values and evaluate a_c:

$$a_c = \frac{4\pi^2(6370\,\text{km})\cos\theta}{[(24\,\text{h})(3600\,\text{s/h})]^2}$$

$$= \boxed{(3.37\,\text{cm/s}^2)\cos\theta,\text{ toward the earth's axis.}}$$

(*b*)

A stone dropped from a hand at a location on earth. The effective weight of the stone is equal to $m\vec{a}_{\text{st, surf}}$, where $\vec{a}_{\text{st, surf}}$ is the acceleration of the falling stone (neglecting air resistance) relative to the local surface of the earth. The gravitational force on the stone is equal to $m\vec{a}_{\text{st,iner}}$, where $\vec{a}_{\text{st, iner}}$ is the acceleration of the local surface of the earth relative to the inertial frame (the acceleration of the surface due to the rotation of the earth). Multiplying through this equation by m and rearranging gives $m\vec{a}_{\text{st, surf}} = m\vec{a}_{\text{st, iner}} - m\vec{a}_{\text{surf, iner}}$, which relates the apparent weight to the acceleration due to gravity and the acceleration due to the earth's rotation. A vector addition diagram can be used to show that the magnitude of $m\vec{a}_{\text{st, surf}}$ is slightly less than that of $m\vec{a}_{\text{st, iner}}$.

(*c*) At the equator, the gravitational acceleration and the radial acceleration are both directed toward the center of the earth. Therefore:

$$g = g_{\text{eff}} + a_c$$
$$= 978\,\text{cm/s}^2 + (3.37\,\text{cm/s}^2)\cos 0°$$
$$= \boxed{981.4\,\text{cm/s}^2}$$

At latitude θ the gravitational acceleration points toward the center of the earth whereas the centripetal acceleration points toward the axis of rotation. Use the law of cosines to relate g_{eff}, g, and a_c:

$$g_{\text{eff}}^2 = g^2 + a_c^2 - 2ga_c\cos\theta$$

Substitute for θ, g_{eff}, and a_c and simplify to obtain the quadratic equation:

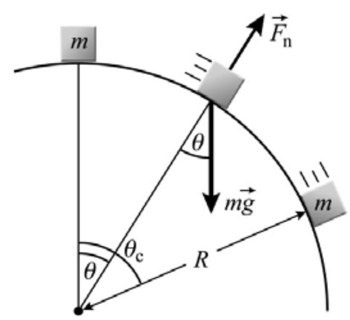
$$g^2 - (4.75\,\text{cm/s}^2)g - 962350\,\text{cm}^2/\text{s}^4 = 0$$

Solve for the physically meaningful (i.e., positive) root to obtain:

$$g = \boxed{983\,\text{cm/s}^2}$$

***118 •••**

Picture the Problem The diagram shows the block in its initial position, an intermediate position, and as it is separating from the sphere. Because the sphere is frictionless, the only forces acting on the block are the normal and gravitational forces. We'll apply Newton's 2nd law and set F_n equal to zero to determine the angle θ_c at which the block leaves the surface.



Taking the inward direction to be positive, apply $\sum F_r = ma_r$ to the block:

$$mg\cos\theta - F_n = m\frac{v^2}{R}$$

Apply the separation condition to obtain:

$$mg\cos\theta_c = m\frac{v^2}{R}$$

Solve for $\cos\theta_c$:

$$\cos\theta_c = \frac{v^2}{gR} \qquad (1)$$

Apply $\sum F_t = ma_t$ to the block:

$$mg\sin\theta = ma_t$$

or

$$a_t = \frac{dv}{dt} = g\sin\theta$$

Note that a is not constant and, hence, we cannot use constant-acceleration equations.

Multiply the left-hand side of the equation by one in the form of $d\theta/d\theta$ and rearrange to obtain:

$$\frac{dv}{dt}\frac{d\theta}{d\theta} = g\sin\theta$$

and

$$\frac{d\theta}{dt}\frac{dv}{d\theta} = g\sin\theta$$

Relate the arc distance s the block travels to the angle θ and the radius R of the sphere:

$$\theta = \frac{s}{R} \text{ and } \frac{d\theta}{dt} = \frac{1}{R}\frac{ds}{dt} = \frac{v}{R}$$

where v is the block's instantaneous speed.

Substitute to obtain:

$$\frac{v}{R}\frac{dv}{d\theta} = g\sin\theta$$

Separate the variables and integrate from $v' = 0$ to v and $\theta = 0$ to θ_c:

$$\int_0^v v'dv' = gR\int_0^{\theta_c} \sin\theta d\theta$$

or

$$v^2 = 2gR(1 - \cos\theta_c)$$

Substitute in equation (1) to obtain:

$$\cos\theta_c = \frac{2gR(1-\cos\theta_c)}{gR} = 2(1-\cos\theta_c)$$

Solve for and evaluate θ_c:

$$\theta_c = \cos^{-1}\left(\frac{2}{3}\right) = \boxed{48.2°}$$

Chapter 6
Work and Energy

Conceptual Problems

***1** •

Determine the Concept A force does work on an object when its point of application moves through some distance and there is a component of the force along the line of motion.

(*a*) False. The *net* force acting on an object is the vector sum of all the forces acting on the object and is responsible for displacing the object. Any or all of the forces contributing to the net force may do work.

(*b*) True. The object could be at rest in one reference frame and moving in another. If we consider only the frame in which the object is at rest, then, because it must undergo a displacement in order for work to be done on it, we would conclude that the statement is true.

(*c*) True. A force that is always perpendicular to the velocity of a particle changes neither it's kinetic nor potential energy and, hence, does no work on the particle.

2 •

Determine the Concept If we ignore the work that you do in initiating the horizontal motion of the box and the work that you do in bringing it to rest when you reach the second table, then neither the kinetic nor the potential energy of the system changed as you moved the box across the room. Neither did any forces acting on the box produce displacements. Hence, we must conclude that the minimum work you did on the box is zero.

3 •

False. While it is true that the person's kinetic energy is not changing due to the fact that she is moving at a constant speed, her gravitational potential energy is continuously changing and so we must conclude that the force exerted by the seat on which she is sitting is doing work on her.

***4** •

Determine the Concept The kinetic energy of any object is proportional to the square of its speed. Because $K = \frac{1}{2}mv^2$, replacing v by $2v$ yields

$K' = \frac{1}{2}m(2v)^2 = 4\left(\frac{1}{2}mv^2\right) = 4K.$ Thus doubling the speed of a car quadruples its kinetic energy.

5 •

Determine the Concept No. The work done on any object by any force $\vec{F}$ is defined as $dW = \vec{F} \cdot d\vec{r}$. The direction of $\vec{F}_{\text{net}}$ is toward the center of the circle in which the object is traveling and $d\vec{r}$ is tangent to the circle. No work is done by the net force because $\vec{F}_{\text{net}}$ and $d\vec{r}$ are perpendicular so the dot product is zero.

6 •

Determine the Concept The kinetic energy of any object is proportional to the square of its speed and is always positive. Because $K = \frac{1}{2}mv^2,$ replacing v by $3v$ yields $K' = \frac{1}{2}m(3v)^2 = 9\left(\frac{1}{2}mv^2\right) = 9K.$ Hence tripling the speed of an object increases its kinetic energy by a factor of 9 and $\boxed{(d) \text{ is correct.}}$

***7** •

Determine the Concept The work required to stretch or compress a spring a distance x is given by $W = \frac{1}{2}kx^2$ where k is the spring's stiffness constant. Because $W \propto x^2$, doubling the distance the spring is stretched will require four times as much work.

8 •

Determine the Concept No. We know that if a *net* force is acting on a particle, the particle must be accelerated. If the *net* force does no work on the particle, then we must conclude that the kinetic energy of the particle is constant and that the *net* force is acting perpendicular to the direction of the motion and will cause a departure from straight-line motion.

9 •

Determine the Concept We can use the definition of power as the scalar product of force and velocity to express the dimension of power.

Power is defined as:	$P \equiv \vec{F} \cdot \vec{v}$
Express the dimension of force:	$[M][L/T^2]$
Express the dimension of velocity:	$[L/T]$
Express the dimension of power in terms of those of force and velocity:	$[M][L/T^2][L/T] = [M][L]^2/[T]^3$ and $\boxed{(d) \text{ is correct.}}$

10 •

Determine the Concept The change in gravitational potential energy, over elevation changes that are small enough so that the gravitational field can be considered constant, is $mg\Delta h$, where Δh is the elevation change. Because Δh is the same for both Sal and Joe, their gains in gravitational potential energy are the same. $\boxed{(c) \text{ is correct.}}$

11 •

(*a*) False. The definition of work is not limited to displacements caused by conservative forces.

(*b*) False. Consider the work done by the gravitational force on an object in freefall.

(*c*) True. This is the definition of work done by a conservative force.

***12** ••

Picture the Problem F_x is defined to be the negative of the derivative of the potential function with respect to *x*; i.e., $F_x = -dU/dx$.

(*a*) Examine the slopes of the curve at each of the lettered points, remembering that F_x is the negative of the slope of the potential energy graph, to complete the table:

Point	dU/dx	F_x
A	+	–
B	0	0
C	–	+
D	0	0
E	+	–
F	0	0

(*b*) Find the point where the slope is steepest:

$\boxed{\text{At point } C \left|F_x\right| \text{ is greatest.}}$

(*c*) If $d^2U/dx^2 < 0$, then the curve is concave downward and the equilibrium is *unstable*.

$\boxed{\text{At point } B \text{ the equilibrium is unstable.}}$

If $d^2U/dx^2 > 0$, then the curve is concave upward and the equilibrium is *stable*.

$\boxed{\text{At point } D \text{ the equilibrium is stable.}}$

Remarks: At point *F*, $d^2U/dx^2 = 0$ and the equilibrium is neither *stable* nor *unstable*; it is said to be *neutral*.

13 •

(*a*) False. Any force acting on an object may do work depending on whether the force produces a displacement … or is displaced as a consequence of the object's motion.

(*b*) False. Consider an element of area under a force-versus-time graph. Its units are N·s whereas the units of work are N·m.

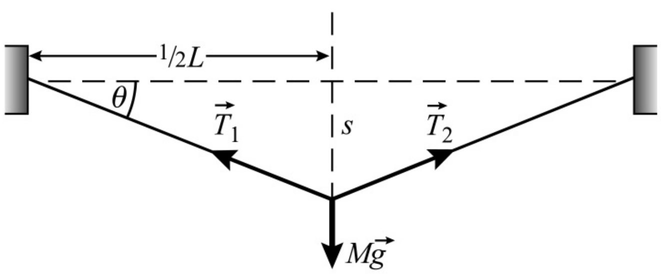
14 •

Determine the Concept Work $dW\left(=\vec{F}\cdot d\vec{s}\right)$ is done when a force $\vec{F}$ produces a displacement $d\vec{s}$. Because $\vec{F}\cdot d\vec{s} \equiv Fds\cos\theta = \left(F\cos\theta\right)ds$, W will be negative if the value of θ is such that $F\cos\theta$ is negative. $\boxed{(d)\text{ is correct.}}$

Estimation and Approximation

***15** ••

Picture the Problem The diagram depicts the situation when the tightrope walker is at the center of rope. M represents her mass and the vertical components of tensions $\vec{T}_1$ and $\vec{T}_2$, equal in magnitude, support her weight. We can apply a condition for static equilibrium in the vertical direction to relate the tension in the rope to the angle θ and use trigonometry to find s as a function of θ.



(*a*) Use trigonometry to relate the sag s in the rope to its length L and θ:

$$\tan\theta = \frac{s}{\frac{1}{2}L} \text{ and } s = \frac{L}{2}\tan\theta$$

Apply $\sum F_y = 0$ to the tightrope walker when she is at the center of the rope to obtain:

$2T\sin\theta - Mg = 0$ where T is the magnitude of $\vec{T}_1$ and $\vec{T}_2$.

Solve for θ to obtain:

$$\theta = \sin^{-1}\left(\frac{Mg}{2T}\right)$$

Substitute numerical values and evaluate θ:

$$\theta = \sin^{-1}\left[\frac{(50\,\text{kg})(9.81\,\text{m/s}^2)}{2(5000\,\text{N})}\right] = 2.81°$$

Substitute to obtain:

$$s=\frac{10\,\text{m}}{2}\tan 2.81^\circ=\boxed{0.245\,\text{m}}$$

(*b*) Express the change in the tightrope walker's gravitational potential energy as the rope sags:

$$\Delta U=U_{\text{at center}}-U_{\text{end}}=Mg\Delta y$$

Substitute numerical values and evaluate ΔU:

$$\Delta U=(50\,\text{kg})(9.81\,\text{m/s}^2)(-0.245\,\text{m})=\boxed{-120\,\text{J}}$$

16 •

Picture the Problem You can estimate your change in potential energy due to this change in elevation from the definition of ΔU. You'll also need to estimate the height of one story of the Empire State building. We'll assume your mass is 70 kg and the height of one story to be 3.5 m. This approximation gives us a height of 1170 ft (357 m), a height that agrees to within 7% with the actual height of 1250 ft from the ground floor to the observation deck. We'll also assume that it takes 3 min to ride non-stop to the top floor in one of the high-speed elevators.

(*a*) Express the change in your gravitational potential energy as you ride the elevator to the 102nd floor:

$$\Delta U=mg\Delta h$$

Substitute numerical values and evaluate ΔU:

$$\Delta U=(70\,\text{kg})(9.81\,\text{m/s}^2)(357\,\text{m})=\boxed{245\,\text{kJ}}$$

(*b*) Ignoring the acceleration intervals at the beginning and the end of your ride, express the work done on you by the elevator in terms of the change in your gravitational potential energy:

$$W=Fh=\Delta U$$

Solve for and evaluate F:

$$F=\frac{\Delta U}{h}=\frac{245\,\text{kJ}}{357\,\text{m}}=\boxed{686\,\text{N}}$$

(*c*) Assuming a 3 minute ride to the top, express and evaluate the average power delivered to the elevator:

$$P=\frac{\Delta U}{\Delta t}=\frac{245\,\text{kJ}}{(3\,\text{min})(60\,\text{s/min})}=\boxed{1.36\,\text{kW}}$$

17 •

Picture the Problem We can find the kinetic energy K of the spacecraft from its definition and compare its energy to the annual consumption in the U.S. W by examining the ratio K/W.

Using its definition, express and evaluate the kinetic energy of the spacecraft:

$$K = \tfrac{1}{2}mv^2 = \tfrac{1}{2}(10000\,\text{kg})\left(3\times10^7\text{ m/s}\right)^2$$
$$= 4.50\times10^{18}\text{ J}$$

Express this amount of energy as a percentage of the annual consumption in the United States:

$$\frac{K}{E} \approx \frac{4.50\times10^{18}\text{ J}}{5\times10^{20}\text{ J}} \approx \boxed{1\%}$$

***18** ••

Picture the Problem We can find the orbital speed of the Shuttle from the radius of its orbit and its period and its kinetic energy from $K = \tfrac{1}{2}mv^2$. We'll ignore the variation in the acceleration due to gravity to estimate the change in the potential energy of the orbiter between its value at the surface of the earth and its orbital value.

(*a*) Express the kinetic energy of the orbiter:

$$K = \tfrac{1}{2}mv^2$$

Relate the orbital speed of the orbiter to its radius r and period T:

$$v = \frac{2\pi r}{T}$$

Substitute and simplify to obtain:

$$K = \tfrac{1}{2}m\left(\frac{2\pi r}{T}\right)^2 = \frac{2\pi^2 mr^2}{T^2}$$

Substitute numerical values and evaluate K:

$$K = \frac{2\pi^2\left(8\times10^4\text{ kg}\right)\left[(200\text{ mi}+3960\text{ mi})(1.609\text{ km/mi})\right]^2}{\left[(90\text{ min})(60\text{ s/min})\right]^2} = \boxed{2.43\text{ TJ}}$$

(*b*) Assuming the acceleration due to gravity to be constant over the 200 mi and equal to its value at the surface of the earth (actually, it is closer to 9 m/s^2 at an elevation of 200 mi), express the change in gravitational potential energy of the orbiter, relative to the surface of the earth, as the Shuttle goes into orbit:

$$\Delta U = mgh$$

Substitute numerical values and evaluate ΔU:

$$\Delta U = \left(8\times10^4\ \text{kg}\right)\left(9.81\,\text{m/s}^2\right)\times\left(200\,\text{mi}\right)\left(1.609\,\text{km/mi}\right) = \boxed{0.253\,\text{TJ}}$$

(*c*) No, they shouldn't be equal because there is more than just the force of gravity to consider here. When the shuttle is resting on the surface of the earth, it is supported against the force of gravity by the normal force the earth exerts upward on it. We would need to take into consideration the change in potential energy of the surface of earth in its deformation under the weight of the shuttle to find the actual change in potential energy.

19 •

Picture the Problem Let's assume that the width of the driveway is 18 ft. We'll also assume that you lift each shovel full of snow to a height of 1 m, carry it to the edge of the driveway, and drop it. We'll ignore the fact that you must slightly accelerate each shovel full as you pick it up and as you carry it to the edge of the driveway. While the density of snow depends on the extent to which it has been compacted, one liter of freshly fallen snow is approximately equivalent to 100 mL of water.

Express the work you do in lifting the snow a distance *h*:

$$W = \Delta U = mgh = \rho_{\text{snow}} V_{\text{snow}} gh$$

where ρ is the density of the snow.

Using its definition, express the densities of water and snow:

$$\rho_{\text{snow}} = \frac{m_{\text{snow}}}{V_{\text{snow}}} \text{ and } \rho_{\text{water}} = \frac{m_{\text{water}}}{V_{\text{water}}}$$

Divide the first of these equations by the second to obtain:

$$\frac{\rho_{\text{snow}}}{\rho_{\text{water}}} = \frac{V_{\text{water}}}{V_{\text{snow}}} \text{ or } \rho_{\text{snow}} = \rho_{\text{water}} \frac{V_{\text{water}}}{V_{\text{snow}}}$$

Substitute and evaluate the ρ_{snow}:

$$\rho_{\text{snow}} = \left(10^3\ \text{kg/m}^3\right)\frac{100\,\text{mL}}{\text{L}} = 100\,\text{kg/m}^3$$

Calculate the volume of snow covering the driveway:

$$V_{\text{snow}} = \left(50\,\text{ft}\right)\left(18\,\text{ft}\right)\left(\frac{10}{12}\,\text{ft}\right) = 750\,\text{ft}^3 \times \frac{28.32\,\text{L}}{\text{ft}^3} \times \frac{10^{-3}\,\text{m}^3}{\text{L}} = 21.2\,\text{m}^3$$

Substitute numerical values in the expression for *W* to obtain an estimate (a lower bound) for the work you would do on the snow in removing it:

$$W = \left(100\,\text{kg/m}^3\right)\left(21.2\,\text{m}^3\right)\left(9.81\,\text{m/s}^2\right)\left(1\,\text{m}\right) = \boxed{20.8\,\text{kJ}}$$

Work and Kinetic Energy

***20 •**

Picture the Problem We can use $\frac{1}{2}mv^2$ to find the kinetic energy of the bullet.

(*a*) Use the definition of *K*:

$$K = \tfrac{1}{2}mv^2 = \tfrac{1}{2}(0.015\,\text{kg})(1.2\times10^3\,\text{m/s})^2 = \boxed{10.8\,\text{kJ}}$$

(*b*) Because $K \propto v^2$:

$$K' = \tfrac{1}{4}K = \boxed{2.70\,\text{kJ}}$$

(*c*) Because $K \propto v^2$:

$$K' = 4K = \boxed{43.2\,\text{kJ}}$$

21 •

Picture the Problem We can use $\frac{1}{2}mv^2$ to find the kinetic energy of the baseball and the jogger.

(*a*) Use the definition of *K*:

$$K = \tfrac{1}{2}mv^2 = \tfrac{1}{2}(0.145\,\text{kg})(45\,\text{m/s})^2 = \boxed{147\,\text{J}}$$

(*b*) Convert the jogger's pace of 9 min/mi into a speed:

$$v = \left(\frac{1\,\text{mi}}{9\,\text{min}}\right)\left(\frac{1\,\text{min}}{60\,\text{s}}\right)\left(\frac{1609\,\text{m}}{1\,\text{mi}}\right) = 2.98\,\text{m/s}$$

Use the definition of *K*:

$$K = \tfrac{1}{2}mv^2 = \tfrac{1}{2}(60\,\text{kg})(2.98\,\text{m/s})^2 = \boxed{266\,\text{J}}$$

22 •

Picture the Problem The work done in raising an object a given distance is the product of the force producing the displacement and the displacement of the object. Because the weight of an object is the gravitational force acting on it and this force acts downward, the work done by gravity is the negative of the weight of the object multiplied by its displacement. The change in kinetic energy of an object is equal to the work done by the *net* force acting on it.

(*a*) Use the definition of *W*:

$$W = \vec{F}\cdot\Delta\vec{y} = F\Delta y$$

$= (80\text{ N})(3\text{ m}) = \boxed{240\text{ J}}$

(*b*) Use the definition of *W*:

$W = \vec{F}\cdot\Delta\vec{y} = -mg\Delta y$, because $\vec{F}$ and $\Delta\vec{y}$ are in opposite directions.

$\therefore\ W = -(6\text{ kg})(9.81\text{ m/s}^2)(3\text{ m})$
$= \boxed{-177\text{ J}}$

(*c*) According to the work-kinetic energy theorem:

$K = W + W_g = 240\text{ J} + (-177\text{ J})$
$= \boxed{63.0\text{ J}}$

23 •

Picture the Problem The constant force of 80 N is the net force acting on the box and the work it does is equal to the *change* in the kinetic energy of the box.

Using the work-kinetic energy theorem, relate the work done by the constant force to the *change* in the kinetic energy of the box:

$$W = K_f - K_i = \tfrac{1}{2}m\left(v_f^2 - v_i^2\right)$$

Substitute numerical values and evaluate *W*:

$$W = \tfrac{1}{2}(5\text{ kg})\left[(68\text{ m/s})^2 - (20\text{ m/s})^2\right] = \boxed{10.6\text{ kJ}}$$

***24** ••

Picture the Problem We can use the definition of kinetic energy to find the mass of your friend.

Using the definition of kinetic energy and letting ″1″ denote your mass and speed and ″2″ your girlfriend's, express the equality of your kinetic energies and solve for your girlfriend's mass as a function of both your masses and speeds:

$$\tfrac{1}{2}m_1v_1^2 = \tfrac{1}{2}m_2v_2^2$$

and

$$m_2 = m_1\left(\frac{v_1}{v_2}\right)^2 \qquad (1)$$

Express the condition on your speed that enables you to run at the same speed as your girlfriend:

$$v_2 = 1.25v_1 \qquad (2)$$

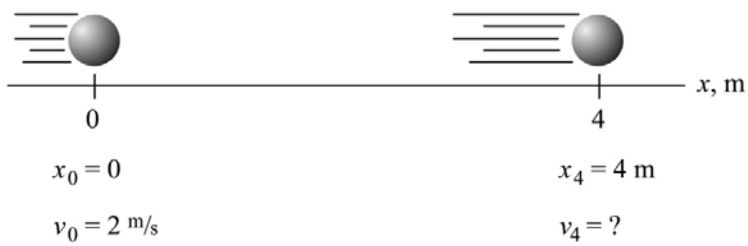
Substitute equation (2) in equation (1) to obtain:

$$m_2 = m_1\left(\frac{v_1}{v_2}\right)^2 = (85\,\text{kg})\left(\frac{1}{1.25}\right)^2 = \boxed{54.4\,\text{kg}}$$

Work Done by a Variable Force

25 ••

Picture the Problem The pictorial representation shows the particle as it moves along the positive x axis. The particle's kinetic energy increases because work is done on it. We can calculate the work done on it from the graph of F_x vs. x and relate its kinetic energy when it is at x = 4 m to its kinetic energy when it was at the origin and the work done on it by using the work-kinetic energy theorem.



(*a*) Calculate the kinetic energy of the particle when it is at x = 0:

$$K_0 = \tfrac{1}{2}mv^2 = \tfrac{1}{2}(3\,\text{kg})(2\,\text{m/s})^2 = \boxed{6.00\,\text{J}}$$

(*b*) Because the force and displacement are parallel, the work done is the area under the curve. Use the formula for the area of a triangle to calculate the area under the F as a function of x graph:

$$W_{0\to4} = \tfrac{1}{2}(\text{base})(\text{altitude}) = \tfrac{1}{2}(4\,\text{m})(6\,\text{N}) = \boxed{12.0\,\text{J}}$$

(*c*) Express the kinetic energy of the particle at x = 4 m in terms of its speed and mass and solve for its speed:

$$v_4 = \sqrt{\frac{2K_4}{m}} \qquad (1)$$

Using the work-kinetic energy theorem, relate the work done on the particle to its *change* in kinetic energy and solve for the particle's kinetic energy at x = 4 m:

$$W_{0\to4} = K_4 - K_0$$

$$K_4 = K_0 + W_{0\to4} = 6.00\,\text{J} + 12.0\,\text{J} = 18.0\,\text{J}$$

Substitute numerical values in equation (1) and evaluate v_4:

$$v_4=\sqrt{\frac{2(18.0\,\text{J})}{3\,\text{kg}}}=\boxed{3.46\,\text{m/s}}$$

***26 ••**

Picture the Problem The work done by this force as it displaces the particle is the area under the curve of *F* as a function of *x*. Note that the constant *C* has units of N/m^3.

Because *F* varies with position non-linearly, express the work it does as an integral and evaluate the integral between the limits *x* = 1.5 m and *x* = 3 m:

$$\begin{aligned}W&=\left(C\,\text{N/m}^3\right)\int_{1.5\,\text{m}}^{3\,\text{m}}x'^3\,dx'\\&=\left(C\,\text{N/m}^3\right)\left[\tfrac{1}{4}x'^4\right]_{1.5\,\text{m}}^{3\,\text{m}}\\&=\frac{\left(C\,\text{N/m}^3\right)}{4}\left[(3\,\text{m})^4-(1.5\,\text{m})^4\right]\\&=\boxed{19C\,\text{J}}\end{aligned}$$

27 ••

Picture the Problem The work done on the dog by the leash as it stretches is the area under the curve of *F* as a function of *x*. We can find this area (the work Lou does holding the leash) by integrating the force function.

Because *F* varies with position non-linearly, express the work it does as an integral and evaluate the integral between the limits *x* = 0 and $x = x_1$:

$$\begin{aligned}W&=\int_0^{x_1}\left(-kx'-ax'^2\right)dx'\\&=\left[-\tfrac{1}{2}kx'^2-\tfrac{1}{3}ax'^3\right]_0^{x_1}\\&=\boxed{-\tfrac{1}{2}kx_1^2-\tfrac{1}{3}ax_1^3}\end{aligned}$$

28 ••

Picture the Problem The work done on an object can be determined by finding the area bounded by its graph of F_x as a function of *x* and the *x* axis. We can find the kinetic energy and the speed of the particle at any point by using the work-kinetic energy theorem.

(*a*) Express *W*, the area under the curve, in terms of the area of one square, A_{square}, and the number of squares *n*:

$$W = n\,A_{\text{square}}$$

Determine the work equivalent of one square:

$$W = (0.5\text{ N})(0.25\text{ m}) = 0.125\text{ J}$$

Estimate the number of squares under the curve between $x = 0$ and $x = 2$ m:

$n \approx 22$

Substitute to determine W:

$$W = 22(0.125\text{ J}) = \boxed{2.75\text{ J}}$$

(b) Relate the kinetic energy of the object at $x = 2$ m, K_2, to its initial kinetic energy, K_0, and the work that was done on it between $x = 0$ and $x = 2$ m:

$$K_2 = K_0 + W_{0\to2}$$
$$= \tfrac{1}{2}(3\text{ kg})(2.40\text{ m/s})^2 + 2.75\text{ J}$$
$$= \boxed{11.4\text{ J}}$$

(c) Calculate the speed of the object at $x = 2$ m from its kinetic energy at the same location:

$$v = \sqrt{\frac{2K_2}{m}} = \sqrt{\frac{2(11.4\text{ J})}{3\text{ kg}}} = \boxed{2.76\text{ m/s}}$$

(d) Estimate the number of squares under the curve between $x = 0$ and $x = 4$ m:

$n \approx 26$

Substitute to determine W:

$$W = 26(0.125\text{ J}) = \boxed{3.25\text{ J}}$$

(e) Relate the kinetic energy of the object at $x = 4$ m, K_4, to its initial kinetic energy, K_0, and the work that was done on it between $x = 0$ and $x = 4$ m:

$$K_4 = K_0 + W_{0\to4}$$
$$= \tfrac{1}{2}(3\text{ kg})(2.40\text{ m/s})^2 + 3.25\text{ J}$$
$$= 11.9\text{ J}$$

Calculate the speed of the object at $x = 4$ m from its kinetic energy at the same location:

$$v = \sqrt{\frac{2K_4}{m}} = \sqrt{\frac{2(11.9\text{ J})}{3\text{ kg}}} = \boxed{2.82\text{ m/s}}$$

***29** ••

Picture the Problem We can express the mass of the water in Margaret's bucket as the difference between its initial mass and the product of the rate at which it loses water and her position during her climb. Because Margaret must do work against gravity in lifting and carrying the bucket, the work she does is the integral of the product of the gravitational field and the mass of the bucket as a function of its position.

(a) Express the mass of the bucket and the water in it as a function of

$$m(y) = 40\text{ kg} - ry$$

its initial mass, the rate at which it is losing water, and Margaret's position, y, during her climb:

Find the rate, $r=\frac{\Delta m}{\Delta y}$, at which Margaret's bucket loses water:

$$r=\frac{\Delta m}{\Delta y}=\frac{20\,\text{kg}}{20\,\text{m}}=1\,\text{kg/m}$$

Substitute to obtain:

$$m(y)=40\,\text{kg}-ry=\boxed{40\,\text{kg}-\frac{1\,\text{kg}}{\text{m}}y}$$

(b) Integrate the force Margaret exerts on the bucket, $m(y)g$, between the limits of $y = 0$ and $y = 20$ m:

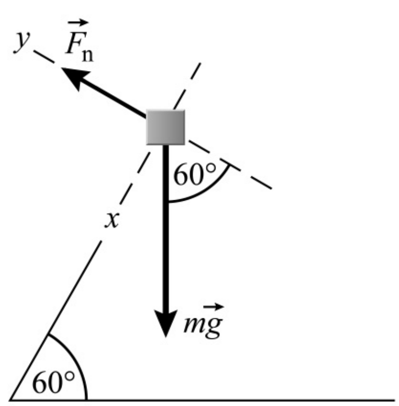
$$W=g\int_0^{20\,\text{m}}\left(40\,\text{kg}-\frac{1\,\text{kg}}{\text{m}}y'\right)dy'=\left(9.81\,\text{m/s}^2\right)\left[(40\,\text{kg})y'-\tfrac{1}{2}(1\,\text{kg/m})y'^2\right]_0^{20\,\text{m}}=\boxed{5.89\,\text{kJ}}$$

Remarks: We could also find the work Margaret did on the bucket, at least approximately, by plotting a graph of *m*(*y*)*g* and finding the area under this curve between *y* = 0 and *y* = 20 m.

Work, Energy, and Simple Machines

30 •

Picture the Problem The free-body diagram shows the forces that act on the block as it slides down the frictionless incline. We can find the work done by these forces as the block slides 2 m by finding their components in the direction of, or opposite to, the motion. When we have determined the work done on the block, we can use the work-kinetic energy theorem or a constant-acceleration equation to calculate its kinetic energy and its speed at any given location.



(*a*) From the free-body diagram, we see that the forces acting on the block are a gravitational force that acts downward and the normal force that the incline exerts perpendicularly to the incline.

Identify the component of *mg* that acts down the incline and calculate the work done by it:

$F_x = mg \sin 60°$

Express the work done by this force:

$W = F_x \Delta x = mg\Delta x \sin 60°$

Substitute numerical values and evaluate *W*:

$$W = (6\,\text{kg})(9.81\,\text{m/s}^2)(2\,\text{m})\sin 60° = \boxed{102\ \text{J}}$$

Remarks: F_n and mgcos60°, being perpendicular to the motion, do no work on the block

(*b*) The total work done on the block is the work done by the net force:

$$W = F_{\text{net}}\Delta x = mg\Delta x \sin 60° = (6\,\text{kg})(9.81\,\text{m/s}^2)(2\,\text{m})\sin 60° = \boxed{102\ \text{J}}$$

(*c*) Express the change in the kinetic energy of the block in terms of the distance, Δx, it has moved down the incline:

$\Delta K = K_f - K_i = W = (mg\sin 60°)\Delta x$

or, because $K_i = 0$,

$K_f = W = (mg\sin 60°)\Delta x$

Relate the speed of the block when it has moved a distance Δx down the incline to its kinetic energy at that location:

$$v = \sqrt{\frac{2K}{m}} = \sqrt{\frac{2mg\Delta x \sin 60°}{m}} = \sqrt{2g\Delta x \sin 60°}$$

Determine this speed when $\Delta x = 1.5$ m:

$$v = \sqrt{2(9.81\,\text{m/s}^2)(1.5\,\text{m})\sin 60°} = \boxed{5.05\,\text{m/s}}$$

(*d*) As in part (*c*), express the change in the kinetic energy of the block in terms of the distance, Δx, it has moved down the incline and

$\Delta K = K_f - K_i$

$= W$

$= (mg \sin 60°)\Delta x$

and

solve for K_f: $K_f = (mg\sin 60°)\Delta x + K_i$

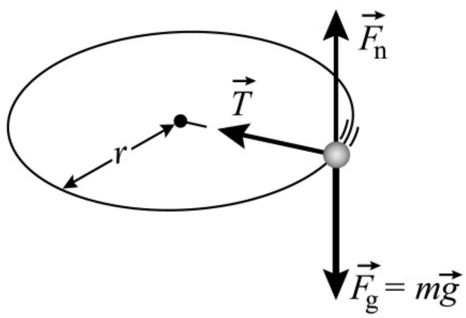
Substitute for the kinetic energy terms and solve for v_f to obtain: $v_f = \sqrt{2g\sin 60°\Delta x + v_i^2}$

Substitute numerical values and evaluate v_f:

$$v_f = \sqrt{2(9.81\,\text{m/s}^2)(1.5\,\text{m})\sin 60° + (2\,\text{m/s})^2} = \boxed{5.43\,\text{m/s}}$$

31 •

Picture the Problem The free-body diagram shows the forces acting on the object as in moves along its circular path on a frictionless horizontal surface. We can use Newton's 2nd law to obtain an expression for the tension in the string and the definition of work to determine the amount of work done by each force during one revolution.



(*a*) Apply $\sum F_r = ma_r$ to the 2-kg object and solve for the tension:

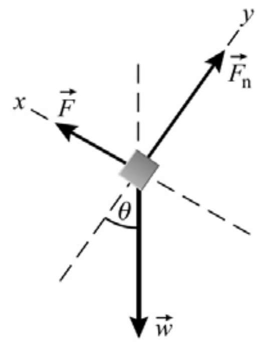
$$T = m\frac{v^2}{r} = (2\,\text{kg})\frac{(2.5\,\text{m/s})^2}{3\,\text{m}} = \boxed{4.17\,\text{N}}$$

(*b*) From the FBD we can see that the forces acting on the object are: $\boxed{\vec{T}, \vec{F}_g, \text{ and } \vec{F}_n}$

$\boxed{\text{Because all of these forces act perpendicularly to the direction of motion of the object, none of them do any work.}}$

***32** •

Picture the Problem The free-body diagram, with $\vec{F}$ representing the force required to move the block at constant speed, shows the forces acting on the block. We can apply Newton's 2nd law to the block to relate F to its weight w and then use the definition of the mechanical advantage of an inclined plane. In the second part of the problem we'll use the definition of work.



(*a*) Express the mechanical advantage M of the inclined plane:

$$M = \frac{w}{F}$$

Apply $\sum F_x = ma_x$ to the block:

$F - w\sin\theta = 0$ because $a_x = 0$.

Solve for F and substitute to obtain:

$$M = \frac{w}{w\sin\theta} = \frac{1}{\sin\theta}$$

Refer to the figure to obtain:

$$\sin\theta = \frac{H}{L}$$

Substitute to obtain:

$$M = \boxed{\frac{1}{\sin\theta} = \frac{L}{H}}$$

(*b*) Express the work done pushing the block up the ramp:

$$W_{\text{ramp}} = FL = mgL\sin\theta$$

Express the work done lifting the block into the truck:

$$W_{\text{lifting}} = mgH = mgL\sin\theta$$

and

$$\boxed{W_{\text{ramp}} = W_{\text{lifting}}}$$

33 •

Picture the Problem We can find the work done per revolution in lifting the weight and the work done in each revolution of the handle and then use the definition of mechanical advantage.

Express the mechanical advantage of the jack:

$$M = \frac{W}{F}$$

Express the work done by the jack in one complete revolution (the weight W is raised a distance p):

$$W_{\text{lifting}} = Wp$$

Express the work done by the force F in one complete revolution:

$$W_{\text{turning}} = 2\pi RF$$

Equate these expressions to obtain: $Wp = 2\pi RF$

Solve for the ratio of W to F: $M = \frac{W}{F} = \boxed{\frac{2\pi R}{p}}$

Remarks: One does the same amount of work turning as lifting; exerting a smaller force over a greater distance.

34 •

Picture the Problem The object whose weight is $\vec{w}$ is supported by two portions of the rope resulting in what is known as a *mechanical advantage* of 2. The work that is done in each instance is the product of the force doing the work and the displacement of the object on which it does the work.

(*a*) If w moves through a distance h: F moves a distance $\boxed{2h}$

(*b*) Assuming that the kinetic energy of the weight does not change, relate the work done on the object to the change in its potential energy to obtain: $W = \Delta U = wh\cos\theta = \boxed{wh}$

(*c*) Because the force you exert on the rope and its displacement are in the same direction: $W = F(2h)\cos\theta = F(2h)$

Determine the tension in the ropes supporting the object:

$$\sum F_{\text{vertical}} = 2F - w = 0$$

and

$$F = \tfrac{1}{2}w$$

Substitute for F: $W = F(2h) = \tfrac{1}{2}w(2h) = \boxed{wh}$

(*d*) The mechanical advantage of the inclined plane is the ratio of the weight that is lifted to the force required to lift it, i.e.: $M = \frac{w}{F} = \frac{w}{\frac{1}{2}w} = \boxed{2}$

Remarks: Note that the mechanical advantage is also equal to the number of ropes supporting the load.

Dot Products

***35** •

Picture the Problem Because $\vec{A}\cdot\vec{B} \equiv AB\cos\theta$ we can solve for $\cos\theta$ and use the fact that $\vec{A}\cdot\vec{B} = -AB$ to find θ.

Solve for θ:

$$\theta = \cos^{-1}\frac{\vec{A}\cdot\vec{B}}{AB}$$

Substitute for $\vec{A}\cdot\vec{B}$ and evaluate θ:

$$\theta = \cos^{-1}(-1) = \boxed{180°}$$

36 •

Picture the Problem We can use its definition to evaluate $\vec{A}\cdot\vec{B}$.

Express the definition of $\vec{A}\cdot\vec{B}$:

$$\vec{A}\cdot\vec{B} = AB\cos\theta$$

Substitute numerical values and evaluate $\vec{A}\cdot\vec{B}$:

$$\vec{A}\cdot\vec{B} = (6\,\text{m})(6\,\text{m})\cos 60° = \boxed{18.0\,\text{m}^2}$$

37 •

Picture the Problem The scalar product of two-dimensional vectors $\vec{A}$ and $\vec{B}$ is $A_xB_x + A_yB_y$.

(*a*) For $\vec{A} = 3\hat{i} - 6\hat{j}$ and $\vec{B} = -4\hat{i} + 2\hat{j}$:

$$\vec{A}\cdot\vec{B} = (3)(-4) + (-6)(2) = \boxed{-24}$$

(*b*) For $\vec{A} = 5\hat{i} + 5\hat{j}$ and $\vec{B} = 2\hat{i} - 4\hat{j}$:

$$\vec{A}\cdot\vec{B} = (5)(2) + (5)(-4) = \boxed{-10}$$

(*c*) For $\vec{A} = 6\hat{i} + 4\hat{j}$ and $\vec{B} = 4\hat{i} - 6\hat{j}$:

$$\vec{A}\cdot\vec{B} = (6)(4) + (4)(-6) = \boxed{0}$$

38 •

Picture the Problem The scalar product of two-dimensional vectors $\vec{A}$ and $\vec{B}$ is $AB\cos\theta = A_xB_x + A_yB_y$. Hence the angle between vectors $\vec{A}$ and $\vec{B}$ is given by

$$\theta = \cos^{-1}\frac{A_xB_x + A_yB_y}{AB}.$$

(*a*) For $\vec{A} = 3\hat{i} - 6\hat{j}$ and $\vec{B} = -4\hat{i} + 2\hat{j}$:

$$\vec{A}\cdot\vec{B} = (3)(-4) + (-6)(2) = -24$$

$$A = \sqrt{(3)^2 + (-6)^2} = \sqrt{45}$$

$$B = \sqrt{(-4)^2 + (2)^2} = \sqrt{20}$$

and

$$\theta = \cos^{-1}\frac{-24}{\sqrt{45}\sqrt{20}} = \boxed{143°}$$

(*b*) For $\vec{A} = 5\hat{i} + 5\hat{j}$ and $\vec{B} = 2\hat{i} - 4\hat{j}$:

$$\vec{A}\cdot\vec{B} = (5)(2) + (5)(-4) = -10$$

$$A = \sqrt{(5)^2 + (5)^2} = \sqrt{50}$$

$$B = \sqrt{(2)^2 + (-4)^2} = \sqrt{20}$$

and

$$\theta = \cos^{-1}\frac{-10}{\sqrt{50}\sqrt{20}} = \boxed{108°}$$

(*c*) For $\vec{A} = 6\hat{i} + 4\hat{j}$ and $\vec{B} = 4\hat{i} - 6\hat{j}$:

$$\vec{A}\cdot\vec{B} = (6)(4) + (4)(-6) = \boxed{0}$$

$$A = \sqrt{(6)^2 + (4)^2} = \sqrt{52}$$

$$B = \sqrt{(4)^2 + (-6)^2} = \sqrt{52}$$

and

$$\theta = \cos^{-1}\frac{0}{\sqrt{52}\sqrt{52}} = \boxed{90.0°}$$

39 •

Picture the Problem The work W done by a force $\vec{F}$ during a displacement $\Delta\vec{s}$ for which it is responsible is given by $\vec{F}\cdot\Delta\vec{s}$.

(*a*) Using the definitions of work and the scalar product, calculate the work done by the given force during the specified displacement:

$$W = \vec{F}\cdot\Delta\vec{s}$$
$$= \left(2\,\text{N}\,\hat{i} - 1\,\text{N}\,\hat{j} + 1\,\text{N}\,\hat{k}\right)\cdot\left(3\,\text{m}\,\hat{i} + 3\,\text{m}\,\hat{j} - 2\,\text{m}\,\hat{k}\right)$$
$$= \left[(2)(3) + (-1)(3) + (1)\,(-2)\right]\text{N}\cdot\text{m}$$
$$= \boxed{1.00\,\text{J}}$$

(*b*) Using the definition of work that includes the angle between the force and displacement vectors, solve for the component of $\vec{F}$ in the direction of $\Delta\vec{s}$:

$$W = F\Delta s\cos\theta = (F\cos\theta)\Delta s$$

and

$$F\cos\theta = \frac{W}{\Delta s}$$

Substitute numerical values and evaluate $F\cos\theta$:

$$F\cos\theta = \frac{1\,\text{J}}{\sqrt{(3\,\text{m})^2 + (3\,\text{m})^2 + (-2\,\text{m})^2}} = \boxed{0.213\,\text{N}}$$

40 ••

Picture the Problem The component of a vector that is along another vector is the scalar product of the former vector and a unit vector that is parallel to the latter vector.

(*a*) By definition, the unit vector that is parallel to the vector $\vec{A}$ is:

$$\hat{u}_A = \boxed{\frac{\vec{A}}{A} = \frac{A_x\hat{i} + A_y\hat{j} + A_z\hat{k}}{\sqrt{A_x^2 + A_y^2 + A_z^2}}}$$

(*b*) Find the unit vector parallel to $\vec{B}$:

$$\hat{u}_B = \frac{\vec{B}}{B} = \frac{3\hat{i} + 4\hat{j}}{\sqrt{(3)^2 + (4)^2}} = \frac{3}{5}\hat{i} + \frac{4}{5}\hat{j}$$

The component of $\vec{A}$ along $\vec{B}$ is:

$$\vec{A}\cdot\hat{u}_B = \left(2\hat{i} - \hat{j} - \hat{k}\right)\cdot\left(\frac{3}{5}\hat{i} + \frac{4}{5}\hat{j}\right)$$
$$= (2)\left(\frac{3}{5}\right) + (-1)\left(\frac{4}{5}\right) + (-1)(0)$$
$$= \boxed{0.400}$$

***41** ••

Picture the Problem We can use the definitions of the magnitude of a vector and the dot product to show that if $\left|\vec{A} + \vec{B}\right| = \left|\vec{A} - \vec{B}\right|$, then $\vec{A}\perp\vec{B}$.

Express $\left|\vec{A}+\vec{B}\right|^2$: $\left|\vec{A}+\vec{B}\right|^2=\left(\vec{A}+\vec{B}\right)^2$

Express $\left|\vec{A}-\vec{B}\right|$: $\left|\vec{A}-\vec{B}\right|^2=\left(\vec{A}-\vec{B}\right)^2$

Equate these expressions to obtain: $\left(\vec{A}+\vec{B}\right)^2=\left(\vec{A}-\vec{B}\right)^2$

Expand both sides of the equation to obtain: $A^2+2\vec{A}\cdot\vec{B}+B^2=A^2-2\vec{A}\cdot\vec{B}+B^2$

Simplify to obtain:

$$4\vec{A}\cdot\vec{B}=0$$

or

$$\vec{A}\cdot\vec{B}=0$$

From the definition of the dot product we have:

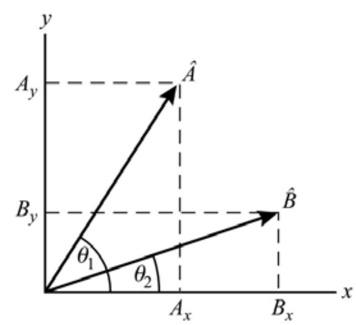
$$\vec{A}\cdot\vec{B}=AB\cos\theta$$

where θ is the angle between $\vec{A}$ and $\vec{B}$.

Because neither $\vec{A}$ nor $\vec{B}$ is the zero vector: $\cos\theta=0 \Rightarrow \theta=90°$ and $\vec{A}\perp\vec{B}$.

42 ••

Picture the Problem The diagram shows the unit vectors $\hat{A}$ and $\hat{B}$ arbitrarily located in the 1st quadrant. We can express these vectors in terms of the unit vectors $\hat{i}$ and $\hat{j}$ and their *x* and *y* components. We can then form the dot product of $\hat{A}$ and $\hat{B}$ to show that $\cos(\theta_1-\theta_2)=\cos\theta_1\cos\theta_2+\sin\theta_1\sin\theta_2$.



(*a*) Express $\hat{A}$ in terms of the unit vectors $\hat{i}$ and $\hat{j}$:

$$\hat{A}=A_x\hat{i}+A_y\hat{j}$$

where

$$A_x=\boxed{\cos\theta_1} \text{ and } A_y=\boxed{\sin\theta_1}$$

Proceed as above to obtain:

$$\hat{B}=B_x\hat{i}+B_y\hat{j}$$

where

$$B_x=\boxed{\cos\theta_2} \text{ and } B_y=\boxed{\sin\theta_2}$$

(*b*) Evaluate $\hat{A}\cdot\hat{B}$:

$$\hat{A}\cdot\hat{B}=\left(\cos\theta_1\hat{i}+\sin\theta_1\hat{j}\right)\cdot\left(\cos\theta_2\hat{i}+\sin\theta_2\hat{j}\right)=\cos\theta_1\cos\theta_2+\sin\theta_1\sin\theta_2$$

From the diagram we note that:

$$\hat{A}\cdot\hat{B}=\cos\left(\theta_1-\theta_2\right)$$

Substitute to obtain:

$$\boxed{\cos(\theta_1 - \theta_2) = \cos\theta_1 \cos\theta_2 + \sin\theta_1 \sin\theta_2}$$

43 •

Picture the Problem In (*a*) we'll show that it does not follow that $\vec{B} = \vec{C}$ by giving a counterexample.

Let $\vec{A} = \hat{i}$, $\vec{B} = 3\hat{i} + 4\hat{j}$ and $\vec{C} = 3\hat{i} - 4\hat{j}$. Form $\vec{A}\cdot\vec{B}$ and $\vec{A}\cdot\vec{C}$:

$$\vec{A}\cdot\vec{B} = \hat{i}\cdot\left(3\hat{i} + 4\hat{j}\right) = 3$$

and

$$\vec{A}\cdot\vec{C} = \hat{i}\cdot\left(3\hat{i} - 4\hat{j}\right) = 3$$

$$\boxed{\text{No. We've shown by a counter-example that } \vec{B} \text{ is not necessarily equal to } \vec{C}.}$$

44 ••

Picture the Problem We can form the dot product of $\vec{A}$ and $\vec{r}$ and require that $\vec{A}\cdot\vec{r} = 1$ to show that the points at the head of all such vectors $\vec{r}$ lie on a straight line. We can use the equation of this line and the components of $\vec{A}$ to find the slope and intercept of the line.

(*a*) Let $\vec{A} = a_x\hat{i} + a_y\hat{j}$. Then:

$$\vec{A}\cdot\vec{r} = \left(a_x\hat{i} + a_y\hat{j}\right)\cdot\left(x\hat{i} + y\hat{j}\right) = a_x x + a_y y = 1$$

Solve for *y* to obtain:

$$y = \boxed{-\frac{a_x}{a_y}x + \frac{1}{a_y}}$$

which is of the form $y = mx + b$ and hence is the equation of a line.

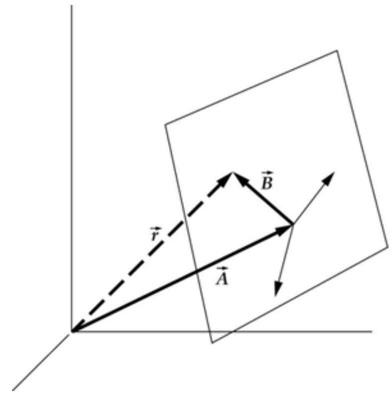
(*b*) Given that $\vec{A} = 2\hat{i} - 3\hat{j}$:

$$m = -\frac{a_x}{a_y} = -\frac{2}{-3} = \boxed{\frac{2}{3}}$$

and

$$b = \frac{1}{a_y} = \frac{1}{-3} = \boxed{-\frac{1}{3}}$$

(*c*) The equation we obtained in (*a*) specifies all vectors whose component parallel to $\vec{A}$ has constant magnitude; therefore, we can write such a vector as $\vec{r}=\frac{\vec{A}}{\left|\vec{A}\right|^2}+\vec{B}$, where $\vec{B}$ is *any* vector perpendicular to $\vec{A}$. This is shown graphically to the right.



Because all possible vectors $\vec{B}$ lie in a plane, the resultant $\vec{r}$ must lie in a plane as well, as is shown above.

***45 ••**

Picture the Problem The rules for the differentiation of vectors are the same as those for the differentiation of scalars and scalar multiplication is commutative.

(*a*) Differentiate $\vec{r}\cdot\vec{r}=r^2=$ constant:

$$\frac{d}{dt}\left(\vec{r}\cdot\vec{r}\right)=\vec{r}\cdot\frac{d\vec{r}}{dt}+\frac{d\vec{r}}{dt}\cdot\vec{r}=2\vec{v}\cdot\vec{r}$$
$$=\frac{d}{dt}\left(\text{constant}\right)=0$$

Because $\vec{v}\cdot\vec{r}=0$:

$$\boxed{\vec{v}\perp\vec{r}}$$

(*b*) Differentiate $\vec{v}\cdot\vec{v}=v^2=$ constant with respect to time:

$$\frac{d}{dt}\left(\vec{v}\cdot\vec{v}\right)=\vec{v}\cdot\frac{d\vec{v}}{dt}+\frac{d\vec{v}}{dt}\cdot\vec{v}=2\vec{a}\cdot\vec{v}$$
$$=\frac{d}{dt}\left(\text{constant}\right)=0$$

Because $\vec{a}\cdot\vec{v}=0$:

$$\boxed{\vec{a}\perp\vec{v}}$$

The results of (*a*) and (*b*) tell us that $\vec{a}$ is perpendicular to $\vec{r}$ and and parallel (or antiparallel) to $\vec{r}$.

(*c*) Differentiate $\vec{v}\cdot\vec{r}=0$ with respect to time:

$$\frac{d}{dt}\left(\vec{v}\cdot\vec{r}\right)=\vec{v}\cdot\frac{d\vec{r}}{dt}+\vec{r}\cdot\frac{d\vec{v}}{dt}$$
$$=v^2+\vec{r}\cdot\vec{a}=\frac{d}{dt}(0)=0$$

Because $v^2 + \vec{r} \cdot \vec{a} = 0$: $\boxed{\vec{r} \cdot \vec{a} = -v^2}$ (1)

Express a_r in terms of θ, where θ is the angle between $\vec{r}$ and $\vec{a}$: $a_r = a\cos\theta$

Express $\vec{r} \cdot \vec{a}$: $\vec{r} \cdot \vec{a} = ra\cos\theta = ra_r$

Substitute in equation (1) to obtain: $ra_r = -v^2$

Solve for a_r: $a_r = \boxed{-\frac{v^2}{r}}$

Power

46 ••

Picture the Problem The power delivered by a force is defined as the rate at which the force does work; i.e., $P = \frac{dW}{dt}$.

Calculate the rate at which force A does work: $P_A = \frac{5\,\text{J}}{10\,\text{s}} = 0.5\,\text{W}$

Calculate the rate at which force B does work: $P_B = \frac{3\,\text{J}}{5\,\text{s}} = 0.6\,\text{W}$ and $\boxed{P_B > P_A}$

47 •

Picture the Problem The power delivered by a force is defined as the rate at which the force does work; i.e., $P = \frac{dW}{dt} = \vec{F} \cdot \vec{v}$.

(*a*) If the box moves upward with a constant velocity, the net force acting it must be zero and the force that is doing work on the box is: $F = mg$

The power input of the force is: $P = Fv = mgv$

Substitute numerical values and evaluate P: $P = (5\,\text{kg})(9.81\,\text{m/s}^2)(2\,\text{m/s}) = \boxed{98.1\,\text{W}}$

(*b*) Express the work done by the force in terms of the rate at which energy is delivered:

$W = Pt = (98.1\text{ W})\,(4\text{ s}) = \boxed{392\text{ J}}$

48 •

Picture the Problem The power delivered by a force is defined as the rate at which the force does work; i.e., $P = \dfrac{dW}{dt} = \vec{F}\cdot\vec{v}$.

(*a*) Using the definition of power, express Fluffy's speed in terms of the rate at which he does work and the force he exerts in doing the work:

$$v = \frac{P}{F} = \frac{6\text{ W}}{3\text{ N}} = \boxed{2\text{ m/s}}$$

(*b*) Express the work done by the force in terms of the rate at which energy is delivered:

$W = Pt = (6\text{ W})\,(4\text{ s}) = \boxed{24.0\text{ J}}$

49 •

Picture the Problem We can use Newton's 2nd law and the definition of acceleration to express the velocity of this object as a function of time. The power input of the force accelerating the object is defined to be the rate at which it does work; i.e., $P = dW/dt = \vec{F}\cdot\vec{v}$.

(*a*) Express the velocity of the object as a function of its acceleration and time:

$v = at$

Apply $\sum\vec{F} = m\vec{a}$ to the object:

$a = F/m$

Substitute for *a* in the expression for *v*:

$$v = \frac{F}{m}t = \frac{5\text{ N}}{8\text{ kg}}t = \boxed{\left(\tfrac{5}{8}\text{ m/s}^2\right)t}$$

(*b*) Express the power input as a function of *F* and *v* and evaluate *P*:

$$P = Fv = (5\text{ N})\left(\tfrac{5}{8}\text{ m/s}^2\right)t = \boxed{3.13t\text{ W/s}}$$

(*c*) Substitute *t* = 3 s:

$$P = (3.13\text{ W/s})(3\text{ s}) = \boxed{9.38\text{ W}}$$

50 •

Picture the Problem The power delivered by a force is defined as the rate at which the force does work; i.e., $P = \frac{dW}{dt} = \vec{F} \cdot \vec{v}$.

(*a*) For $\vec{F}$ = 4 N $\hat{i}$ + 3 N $\hat{k}$ and $\vec{v}$ = 6 m/s $\hat{i}$:

$$P = \vec{F} \cdot \vec{v} = (4\,\text{N}\,\hat{i} + 3\,\text{N}\,\hat{k}) \cdot (6\,\text{m/s}\,\hat{i}) = \boxed{24.0\,\text{W}}$$

(*b*) For $\vec{F}$ = 6 N $\hat{i}$ – 5 N $\hat{j}$ and $\vec{v}$ = – 5 m/s $\hat{i}$ + 4 m/s $\hat{j}$:

$$P = \vec{F} \cdot \vec{v} = (6\,\text{N}\,\hat{i} - 5\,\text{N}\,\hat{j}) \cdot (-5\,\text{m/s}\,\hat{i} + 4\,\text{m/s}\,\hat{j}) = \boxed{-50.0\,\text{W}}$$

(*c*) For $\vec{F}$ = 3 N $\hat{i}$ + 6 N $\hat{j}$ and $\vec{v}$ = 2 m/s $\hat{i}$ + 3 m/s $\hat{j}$:

$$P = \vec{F} \cdot \vec{v} = (3\,\text{N}\,\hat{i} + 6\,\text{N}\,\hat{j}) \cdot (2\,\text{m/s}\,\hat{i} + 3\,\text{m/s}\,\hat{j}) = \boxed{24.0\,\text{W}}$$

***51** •

Picture the Problem Choose a coordinate system in which upward is the positive *y* direction. We can find P_{in} from the given information that $P_{\text{out}} = 0.27P_{\text{in}}$. We can express P_{out} as the product of the tension in the cable *T* and the constant speed *v* of the dumbwaiter. We can apply Newton's 2nd law to the dumbwaiter to express *T* in terms of its mass *m* and the gravitational field *g*.

Express the relationship between the motor's input and output power:

$$P_{\text{out}} = 0.27P_{\text{in}}$$

or

$$P_{\text{in}} = 3.7P_{\text{out}}$$

Express the power required to move the dumbwaiter at a constant speed *v*:

$$P_{\text{out}} = Tv$$

Apply $\sum F_y = ma_y$ to the dumbwaiter:

$$T - mg = ma_y$$

or, because $a_y = 0$,

$$T = mg$$

Substitute to obtain:

$$P_{\text{in}} = 3.7Tv = 3.7mgv$$

Substitute numerical values and evaluate P_{in}:

$$P_{\text{in}} = 3.7(35\,\text{kg})(9.81\,\text{m/s}^2)(0.35\,\text{m/s}) = \boxed{445\,\text{W}}$$

52 ••

Picture the Problem Choose a coordinate system in which upward is the positive y direction. We can express P_{drag} as the product of the drag force F_{drag} acting on the skydiver and her terminal velocity v_t. We can apply Newton's 2nd law to the skydiver to express F_{drag} in terms of her mass m and the gravitational field g.

(a) Express the power due to drag force acting on the skydiver as she falls at her terminal velocity v_t:

$$\vec{P}_{drag} = \vec{F}_{drag} \cdot \vec{v}_t$$

or, because $\vec{F}_{drag}$ and $\vec{v}_t$ are antiparallel,

$$P_{drag} = -F_{drag} v_t$$

Apply $\sum F_y = ma_y$ to the skydiver:

$$F_{drag} - mg = ma_y$$

or, because $a_y = 0$,

$$F_{drag} = mg$$

Substitute to obtain, for the magnitude of P_{drag}:

$$P_{drag} = \left| -mgv_t \right| \qquad (1)$$

Substitute numerical values and evaluate P:

$$P_{drag} = \left| -(55\,\text{kg})(9.81\,\text{m/s}^2)(120\,\frac{\text{mi}}{\text{h}} \times \frac{1\,\text{h}}{3600\,\text{s}} \times \frac{1.609\,\text{km}}{\text{mi}}) \right| = \boxed{2.89 \times 10^4\,\text{W}}$$

(b) Evaluate equation (1) with v = 15 mi/h:

$$P_{drag} = \left| -(55\,\text{kg})(9.81\,\text{m/s}^2)\left(15\frac{\text{mi}}{\text{h}}\right) \times \frac{1\,\text{h}}{3600\,\text{s}} \times \frac{1.609\,\text{km}}{\text{mi}}) \right| = \boxed{3.62\,\text{kW}}$$

***53** ••

Picture the Problem Because, in the absence of air resistance, the acceleration of the cannonball is constant, we can use a constant-acceleration equation to relate its velocity to the time it has been in flight. We can apply Newton's 2nd law to the cannonball to find the net force acting on it and then form the dot product of $\vec{F}$ and $\vec{v}$ to express the rate at which the gravitational field does work on the cannonball. Integrating this expression over the time-of-flight T of the ball will yield the desired result.

Express the velocity of the cannonball as a function of time while it is in the air:

$$\vec{v}(t) = 0\hat{i} + (v_0 - gt)\hat{j}$$

Apply $\sum \vec{F} = m\vec{a}$ to the cannonball to express the force acting on it while it is in the air:

$$\vec{F} = -mg\,\hat{j}$$

Evaluate $\vec{F} \cdot \vec{v}$:

$$\vec{F} \cdot \vec{v} = -mg\,\hat{j} \cdot (v_0 - gt)\hat{j} = -mgv_0 + mg^2 t$$

Relate $\vec{F}\cdot\vec{v}$ to the rate at which work is being done on the cannonball:

$$\frac{dW}{dt}=\vec{F}\cdot\vec{v}=-mgv_0+mg^2t$$

Separate the variables and integrate over the time T that the cannonball is in the air:

$$W=\int_0^T\left(-mgv_0+mg^2t\right)dt=\tfrac{1}{2}mg^2T^2-mgv_0T \qquad (1)$$

Using a constant-acceleration equation, relate the speed v of the cannonball when it lands at the bottom of the cliff to its initial speed v_0 and the height of the cliff H:

$$v^2=v_0^2+2a\Delta y$$

or, because $a = g$ and $\Delta y = H$,

$$v^2=v_0^2+2gH$$

Solve for v to obtain:

$$v=\boxed{\sqrt{{v_0}^2+2gH}}$$

Using a constant-acceleration equation, relate the time-of-flight T to the initial and impact speeds of the cannonball:

$$v=v_0-gT$$

Solve for T to obtain:

$$T=\frac{v_0-v}{g}$$

Substitute for T in equation (1) and simplify to evaluate W:

$$W=\tfrac{1}{2}mg^2\frac{v_0^2-2vv_0+v^2}{g^2}-mgv_0\left(\frac{v_0-v}{g}\right)=\tfrac{1}{2}mv^2-\tfrac{1}{2}mv_0^2=\boxed{\Delta K}$$

54 ••

Picture the Problem If the particle is acted on by a *single* force, that force is the *net* force acting on the particle and is responsible for its acceleration. The rate at which energy is delivered by the force is $P=\vec{F}\cdot\vec{v}$.

Express the rate at which this force does work in terms of $\vec{F}$ and $\vec{v}$:

$$P=\vec{F}\cdot\vec{v}$$

The velocity of the particle, in terms of its acceleration and the time that the force has acted is:

$$\vec{v}=\vec{a}t$$

Using Newton's 2nd law, substitute for $\vec{a}$:

$$\vec{v} = \frac{\vec{F}}{m}t$$

Substitute for $\vec{v}$ in the expression for *P* and simplify to obtain:

$$P = \vec{F} \cdot \frac{\vec{F}}{m}t = \frac{\vec{F} \cdot \vec{F}}{m}t = \boxed{\frac{F^2}{m}t}$$

Potential Energy

55 •

Picture the Problem The change in the gravitational potential energy of the earth-man system, near the surface of the earth, is given by $\Delta U = mg\Delta h$, where Δh is measured relative to an arbitrarily chosen reference position.

Express the change in the man's gravitational potential energy in terms of his change in elevation:

$$\Delta U = mg\Delta h$$

Substitute for *m*, *g* and Δh and evaluate ΔU:

$$\Delta U = (80\,\text{kg})(9.81\,\text{m/s}^2)(6\,\text{m}) = \boxed{4.71\,\text{kJ}}$$

56 •

Picture the Problem The water going over the falls has gravitational potential energy relative to the base of the falls. As the water falls, the falling water acquires kinetic energy until, at the base of the falls; its energy is entirely kinetic. The rate at which energy is delivered to the base of the falls is given by $P = dW/dt = -dU/dt$.

Express the rate at which energy is being delivered to the base of the falls; remembering that half the potential energy of the water is converted to electric energy:

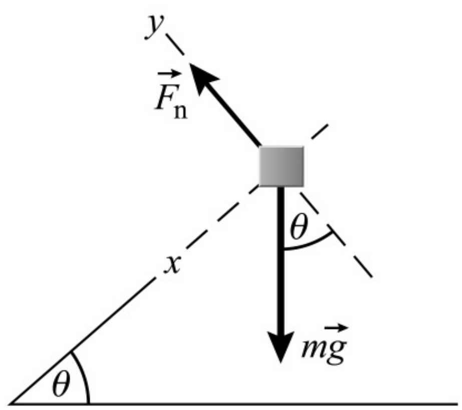
$$P = \frac{dW}{dt} = -\frac{dU}{dt} = -\tfrac{1}{2}\frac{d}{dt}(mgh) = -\tfrac{1}{2}gh\frac{dm}{dt}$$

Substitute numerical values and evaluate *P*:

$$P = -\tfrac{1}{2}(9.81\,\text{m/s}^2)(-128\,\text{m}) \times (1.4\times10^6\ \text{kg/s}) = \boxed{879\,\text{MW}}$$

57 •

Picture the Problem In the absence of friction, the sum of the potential and kinetic energies of the box remains constant as it slides down the incline. We can use the conservation of the mechanical energy of the system to calculate where the box will be and how fast it will be moving at any given time. We can also use Newton's 2nd law to show that the acceleration of the box is constant and constant-acceleration equations to calculate where the box will be and how fast it will be moving at any given time.



(*a*) Express and evaluate the gravitational potential energy of the box, relative to the ground, at the top of the incline:

$U_i = mgh = (2\text{ kg})(9.81\text{ m/s}^2)(20\text{ m}) = \boxed{392\text{ J}}$

(*b*) Using a constant-acceleration equation, relate the displacement of the box to its initial speed, acceleration and time-of-travel:

$$\Delta x = v_0\Delta t + \tfrac{1}{2}a(\Delta t)^2$$

or, because $v_0 = 0$,

$$\Delta x = \tfrac{1}{2}a(\Delta t)^2$$

Apply $\sum F_x = ma_x$ to the box as it slides down the incline and solve for its acceleration:

$$mg\sin\theta = ma \Rightarrow a = g\sin\theta$$

Substitute for a and evaluate $\Delta x(t = 1\text{ s})$:

$$\Delta x(1\text{s}) = \tfrac{1}{2}(g\sin\theta)(\Delta t)^2 = \tfrac{1}{2}(9.81\text{m/s}^2)(\sin 30°)(1\text{s})^2 = \boxed{2.45\text{m}}$$

Using a constant-acceleration equation, relate the speed of the box at any time to its initial speed and acceleration and solve for its speed when $t = 1$ s:

$v = v_0 + at$ where $v_0 = 0$

and

$$v(1\text{s}) = a\Delta t = (g\sin\theta)\Delta t = (9.81\text{m/s}^2)(\sin 30°)(1\text{s}) = \boxed{4.91\text{m/s}}$$

(*c*) Calculate the kinetic energy of the box when it has traveled for 1 s:

$$K = \tfrac{1}{2}mv^2 = \tfrac{1}{2}(2\,\text{kg})(4.91\,\text{m/s})^2 = \boxed{24.1\,\text{J}}$$

Express the potential energy of the box after it has traveled for 1 s in terms of its initial potential energy and its kinetic energy:

$$U = U_\text{i} - K = 392\,\text{J} - 24.1\,\text{J} = \boxed{368\,\text{J}}$$

(*d*) Express the kinetic energy of the box at the bottom of the incline in terms of its initial potential energy and solve for its speed at the bottom of the incline:

$$K = U_i = \tfrac{1}{2}mv^2 = \boxed{392\,\text{J}}$$

and

$$v = \sqrt{\frac{2U_i}{m}}$$

Substitute numerical values and evaluate *v*:

$$v = \sqrt{\frac{2(392\,\text{J})}{2\,\text{kg}}} = \boxed{19.8\,\text{m/s}}$$

58 •

Picture the Problem The potential energy function $U(x)$ is defined by the equation $U(x) - U(x_0) = -\int_{x_0}^{x} F dx.$ We can use the given force function to determine $U(x)$ and then the conditions on U to determine the potential functions that satisfy the given conditions.

(*a*) Use the definition of the potential energy function to find the potential energy function associated with F_x:

$$U(x) = U(x_0) - \int_{x_0}^{x} F_x dx = U(x_0) - \int_{x_0}^{x} (6\,\text{N}) dx' = \boxed{-(6\,\text{N})(x - x_0)}$$

because $U(x_0) = 0$.

(*b*) Use the result obtained in (*a*) to find $U(x)$ that satisfies the condition that $U(4\text{ m}) = 0$:

$$U(4\,\text{m}) = -(6\,\text{N})(4\,\text{m} - x_0) = 0 \Rightarrow x_0 = 4\,\text{m}$$

and

$$U(x) = -(6\,\text{N})(x - 4\,\text{m}) = \boxed{24\,\text{J} - (6\,\text{N})x}$$

(*c*) Use the result obtained in (*a*) to find *U* that satisfies the condition that *U*(6 m) = 14 J:

$$U(6\,\text{m}) = -(6\,\text{N})(6\,\text{m} - x_0) = 14\,\text{J} \Rightarrow x_0 = 50\,\text{m}$$

and

$$U(x) = -(6\,\text{N})\left(x - \frac{25}{3}\,\text{m}\right) = \boxed{50\,\text{J} - (6\,\text{N})x}$$

59 •

Picture the Problem The potential energy of a stretched or compressed ideal spring U_s is related to its force (stiffness) constant *k* and stretch or compression Δx by $U_s = \frac{1}{2}kx^2$.

(*a*) Relate the potential energy stored in the spring to the distance it has been stretched:

$$U_s = \tfrac{1}{2}kx^2$$

Solve for *x*:

$$x = \sqrt{\frac{2U_s}{k}}$$

Substitute numerical values and evaluate *x*:

$$x = \sqrt{\frac{2(50\,\text{J})}{10^4\ \text{N/m}}} = \boxed{0.100\,\text{m}}$$

(*b*) Proceed as in (*a*) with U_s = 100 J:

$$x = \sqrt{\frac{2(100\,\text{J})}{10^4\ \text{N/m}}} = \boxed{0.141\,\text{m}}$$

***60** ••

Picture the Problem In a simple Atwood's machine, the only effect of the pulley is to connect the motions of the two objects on either side of it; i.e., it could be replaced by a piece of polished pipe. We can relate the kinetic energy of the rising and falling objects to the mass of the system and to their common speed and relate their accelerations to the sum and difference of their masses … leading to simultaneous equations in m_1 and m_2.

Use the definition of the kinetic energy of the system to determine the total mass being accelerated:

$$K = \tfrac{1}{2}(m_1 + m_2)v^2$$

and

$$m_1 + m_2 = \frac{2K}{v^2} = \frac{2(80\,\text{J})}{(4\,\text{m/s})^2} = 10.0\,\text{kg} \quad (1)$$

In Chapter 4, the acceleration of the masses was shown to be:

$$a = \frac{m_1 - m_2}{m_1 + m_2}g$$

Because $v(t) = at$, we can eliminate a in the previous equation to obtain:

$$v(t) = \frac{m_1 - m_2}{m_1 + m_2} gt$$

Solve for $m_1 - m_2$:

$$m_1 - m_2 = \frac{(m_1 + m_2)v(t)}{gt}$$

Substitute numerical values and evaluate $m_1 - m_2$:

$$m_1 - m_2 = \frac{(10\,\text{kg})(4\,\text{m/s})}{(9.81\,\text{m/s}^2)(3\,\text{s})} = 1.36\,\text{kg} \quad (2)$$

Solve equations (1) and (2) simultaneously to obtain:

$$m_1 = \boxed{5.68\,\text{kg}} \text{ and } m_2 = \boxed{4.32\,\text{kg}}$$

61 ••

Picture the Problem The gravitational potential energy of this system of two objects is the sum of their individual potential energies and is dependent on an arbitrary choice of where, or under what condition(s), the gravitational potential energy is zero. The best choice is one that simplifies the mathematical details of the expression of U. In this problem let's choose $U = 0$ where $\theta = 0$.

(a) Express U for the 2-object system as the sum of their gravitational potential energies; noting that because the object whose mass is m_2 is above the position we have chosen for $U = 0$, its potential energy is positive while that of the object whose mass is m_1 is negative:

$$\begin{aligned} U(\theta) &= U_1 + U_2 \\ &= m_2 g\ell_2 \sin\theta - m_1 g\ell_1 \sin\theta \\ &= \boxed{(m_2\ell_2 - m_1\ell_1) g \sin\theta} \end{aligned}$$

(b) Differentiate U with respect to θ and set this derivative equal to zero to identify extreme values:

$$\frac{dU}{d\theta} = (m_2\ell_2 - m_1\ell_1) g \cos\theta = 0$$

from which we can conclude that $\cos\theta = 0$ and $\theta = \cos^{-1}0$.

To be physically meaningful, $-\pi/2 \le \theta \le \pi/2$:

$$\therefore \theta = \pm\pi/2$$

Express the 2nd derivative of U with respect to θ and evaluate this derivative at $\theta = \pm\pi/2$:

$$\frac{d^2U}{d\theta^2} = -(m_2\ell_2 - m_1\ell_1) g \sin\theta$$

If we assume, in the expression for U that we derived in (*a*), that $m_2\ell_2 - m_1\ell_1 > 0$, then $U(\theta)$ is a sine function and, in the interval of interest, $-\pi/2 \le \theta \le \pi/2$, takes on its minimum value when $\theta = -\pi/2$:

$$\left.\frac{d^2U}{d\theta^2}\right|_{-\pi/2} > 0$$

and $\boxed{U \text{ is a minimum at } \theta = -\pi/2}$

$$\left.\frac{d^2U}{d\theta^2}\right|_{\pi/2} < 0$$

and $\boxed{U \text{ is a maximum at } \theta = \pi/2}$

(*c*) If $m_1\ell_1 = m_2\ell_2$, then

$$(m_2\ell_2 - m_1\ell_1) = 0$$

and $\boxed{U = 0 \text{ independently of } \theta.}$

Remarks: An alternative approach to establishing the *U* is a maximum at $\theta = \pi/2$ is to plot its graph and note that, in the interval of interest, *U* is concave downward with its maximum value at $\theta = \pi/2$.

Force, Potential Energy, and Equilibrium

62 •

Picture the Problem F_x is defined to be the negative of the derivative of the potential function with respect to x, that is, $F_x = -dU/dx$. Consequently, given U as a function of x, we can find F_x by differentiating U with respect to x.

(*a*) Evaluate $F_x = -\dfrac{dU}{dx}$:

$$F_x = -\frac{d}{dx}\left(Ax^4\right) = \boxed{-4Ax^3}$$

(*b*) Set $F_x = 0$ and solve for x:

$$F_x = 0 \Rightarrow \boxed{x = 0}$$

63 ••

Picture the Problem F_x is defined to be the negative of the derivative of the potential function with respect to x, that is $F_x = -dU/dx$. Consequently, given U as a function of x, we can find F_x by differentiating U with respect to x.

(*a*) Evaluate $F_x = -\dfrac{dU}{dx}$:

$$F_x = -\frac{d}{dx}\left(\frac{C}{x}\right) = \boxed{\frac{C}{x^2}}$$

(*b*) Because $C > 0$:

$\boxed{F_x \text{ is positive for } x \ne 0 \text{ and therefore } \vec{F} \text{ is directed away from the origin.}}$

(*c*) Because U is inversely proportional to x and $C > 0$:

$\boxed{U(x) \text{ decreases with increasing } x.}$

(*d*) With $C < 0$:

$\boxed{F_x \text{ is negative for } x \neq 0 \text{ and therefore } \vec{F} \text{ is directed toward from the origin.}}$

Because U is inversely proportional to x and $C < 0$, $U(x)$ becomes less negative as x increases:

$\boxed{U(x) \text{ increases with increasing } x.}$

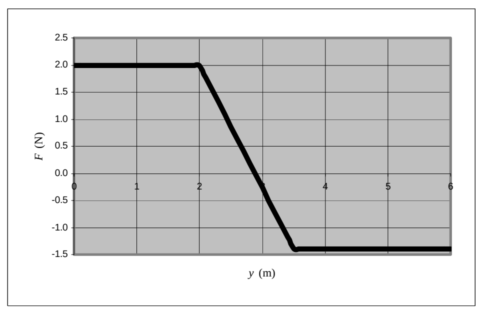
***64** ••

Picture the Problem F_y is defined to be the negative of the derivative of the potential function with respect to y, i.e. $F_y = -dU/dy$. Consequently, we can obtain F_y by examining the slopes of the graph of U as a function of y.

The table to the right summarizes the information we can obtain from Figure 6-40:

	Slope	F_y
Interval	(N)	(N)
$A \to B$	−2	2
$B \to C$	transitional	$-2 \to 1.4$
$C \to D$	1.4	−1.4

The graph of F as a function of y is shown to the right:



65 ••

Picture the Problem F_x is defined to be the negative of the derivative of the potential function with respect to x, i.e. $F_x = -dU/dx$. Consequently, given F as a function of x, we can find U by integrating F_x with respect to x.

Evaluate the integral of F_x with respect to x:

$$U(x) = -\int F(x)dx = -\int \frac{a}{x^2}dx$$

$$= \boxed{\frac{a}{x} + U_0}$$

where U_0 is a constant determined by whatever conditions apply to U.

66 ••

Picture the Problem F_x is defined to be the negative of the derivative of the potential function with respect to *x*, that is, $F_x = -dU/dx$. Consequently, given *U* as a function of *x*, we can find F_x by differentiating *U* with respect to *x*. To determine whether the object is in stable or unstable equilibrium at a given point, we'll evaluate d^2U/dx^2 at the point of interest.

(*a*) Evaluate $F_x = -\frac{dU}{dx}$:

$$F_x = -\frac{d}{dx}\left(3x^2 - 2x^3\right) = \boxed{6x(x-1)}$$

(*b*) We know that, at equilibrium, $F_x = 0$:

When $F_x = 0$, $6x(x - 1) = 0$. Therefore, the object is in equilibrium at $\boxed{x = 0 \text{ and } x = 1\,\text{m.}}$

(*c*) To decide whether the equilibrium at a particular point is stable or unstable, evaluate the 2nd derivative of the potential energy function at the point of interest:

$$\frac{dU}{dx} = \frac{d}{dx}\left(3x^2 - 2x^3\right) = 6x - 6x^2$$

and

$$\frac{d^2U}{dx^2} = 6 - 12x$$

Evaluate $\frac{d^2U}{dx^2}$ at $x = 0$:

$$\left.\frac{d^2U}{dx^2}\right|_{x=0} = 6 > 0$$

$$\Rightarrow \boxed{\text{stable equilibrium at } x = 0}$$

Evaluate $\frac{d^2U}{dx^2}$ at $x = 1$ m:

$$\left.\frac{d^2U}{dx^2}\right|_{x=1\,\text{m}} = 6 - 12 < 0$$

$$\Rightarrow \boxed{\text{unstable equilibrium at } x = 1\,\text{m}}$$

67 ••

Picture the Problem F_x is defined to be the negative of the derivative of the potential function with respect to *x*, i.e. $F_x = -dU/dx$. Consequently, given *U* as a function of *x*, we can find F_x by differentiating *U* with respect to *x*. To determine whether the object is in stable or unstable equilibrium at a given point, we'll evaluate d^2U/dx^2 at the point of interest.

(*a*) Evaluate the negative of the derivative of *U* with respect to *x*:

$$F_x = -\frac{dU}{dx} = -\frac{d}{dx}\left(8x^2 - x^4\right) = 4x^3 - 16x = \boxed{4x(x+2)(x-2)}$$

(*b*) The object is in equilibrium wherever $F_{net} = F_x = 0$:

$4x(x+2)(x-2) = 0 \Rightarrow$ the equilibrium points are $\boxed{x = -2\,\text{m}, 0, \text{and}\ 2\,\text{m}.}$

(*c*) To decide whether the equilibrium at a particular point is stable or unstable, evaluate the 2nd derivative of the potential energy function at the point of interest:

$$\frac{d^2U}{dx^2} = \frac{d}{dx}\left(16x - 4x^3\right) = 16 - 12x^2$$

Evaluate $\frac{d^2U}{dx^2}$ at $x = -2$ m:

$$\left.\frac{d^2U}{dx^2}\right|_{x=-2\,\text{m}} = -32 < 0$$

$$\Rightarrow \boxed{\text{unstable equilibrium at } x = -2\,\text{m}}$$

Evaluate $\frac{d^2U}{dx^2}$ at $x = 0$:

$$\left.\frac{d^2U}{dx^2}\right|_{x=0} = 16 > 0$$

$$\Rightarrow \boxed{\text{stable equilibrium at } x = 0}$$

Evaluate $\frac{d^2U}{dx^2}$ at $x = 2$ m:

$$\left.\frac{d^2U}{dx^2}\right|_{x=2\,\text{m}} = -32 < 0$$

$$\Rightarrow \boxed{\text{unstable equilibrium at } x = 2\,\text{m}}$$

Remarks: You could also decide whether the equilibrium positions are stable or unstable by plotting *F*(*x*) and examining the curve at the equilibrium positions.

68 ••

Picture the Problem F_x is defined to be the negative of the derivative of the potential function with respect to *x*, i.e. $F_x = -dU/dx$. Consequently, given *F* as a function of *x*, we can find *U* by integrating F_x with respect to *x*. Examination of d^2U/dx^2 at extreme points will determine the nature of the stability at these locations.

Determine the equilibrium locations by setting $F_{net} = F(x) = 0$:

$F(x) = x^3 - 4x = x(x^2 - 4) = 0$

$\therefore$ the positions of stable and unstable equilibrium are at $\boxed{x = -2, 0 \text{ and } 2}$.

Evaluate the negative of the integral of $F(x)$ with respect to x:

$$U(x) = -\int F(x)$$
$$= -\int (x^3 - 4x)dx$$
$$= -\frac{x^4}{4} + 2x^2 + U_0$$

where U_0 is a constant whose value is determined by conditions on $U(x)$.

Differentiate $U(x)$ twice:

$$\frac{dU}{dx} = -F_x = -x^3 + 4x$$

and

$$\frac{d^2U}{dx^2} = -3x^2 + 4$$

Evaluate $\frac{d^2U}{dx^2}$ at $x = -2$:

$$\left.\frac{d^2U}{dx^2}\right|_{x=-2} = -8 < 0$$

$\therefore$ $\boxed{\text{the equilibrium is unstable at } x = -2}$

Evaluate $\frac{d^2U}{dx^2}$ at $x = 0$:

$$\left.\frac{d^2U}{dx^2}\right|_{x=0} = 4 > 0$$

$\therefore$ $\boxed{\text{the equilibrium is stable at } x = 0}$

Evaluate $\frac{d^2U}{dx^2}$ at $x = 2$:

$$\left.\frac{d^2U}{dx^2}\right|_{x=2} = -8 < 0$$

$\therefore$ $\boxed{\text{the equilibrium is unstable at } x = 2}$

Thus $U(x)$ has a local minimum at $x = 0$ and local maxima at $x = \pm 2$.

69 ••

Picture the Problem F_x is defined to be the negative of the derivative of the potential function with respect to x, i.e. $F_x = -dU/dx$. Consequently, given U as a function of x, we can find F_x by differentiating U with respect to x. To determine whether the object is in stable or unstable equilibrium at a given point, we can examine the graph of U.

(a) Evaluate $F_x = -\frac{dU}{dx}$ for $x \le 3$ m:

$$F_x = -\frac{d}{dx}\left(3x^2 - x^3\right) = 3x\left(2 - x\right)$$

Set $F_x = 0$ to identify those values of x for which the 4-kg object is in equilibrium:

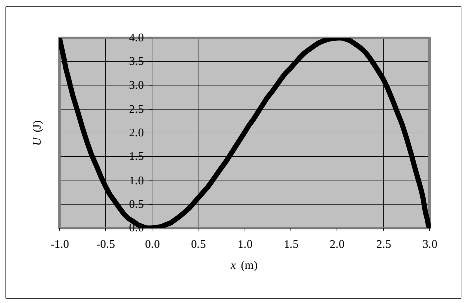
When $F_x = 0$, $3x(2 - x) = 0$.
Therefore, the object is in equilibrium at $\boxed{x = 0 \text{ and } x = 2\,\text{m.}}$

Evaluate $F_x = -\frac{dU}{dx}$ for $x > 3$ m:

$F_x = 0$
because $U = 0$.

$\boxed{\text{Therefore, the object is in neutral equilibrium for } x > 3\,\text{m.}}$

(b) A graph of $U(x)$ in the interval $-1\text{ m} \le x \le 3$ m is shown to the right:



(c) From the graph, $U(x)$ is a minimum at $x = 0$:

$\therefore$ $\boxed{\text{stable equilibrium at } x = 0}$

From the graph, $U(x)$ is a maximum at $x = 2$ m:

$\therefore$ $\boxed{\text{unstable equilibrium at } x = 2\,\text{m}}$

(d) Relate the kinetic energy of the object to its total energy and its potential energy:

$$K = \tfrac{1}{2}mv^2 = E - U$$

Solve for v:

$$v = \sqrt{\frac{2\left(E - U\right)}{m}}$$

Evaluate $U(x = 2\text{ m})$:

$$U\left(x = 2\,\text{m}\right) = 3\left(2\right)^2 - \left(2\right)^3 = 4\,\text{J}$$

Substitute in the equation for v to obtain:

$$v = \sqrt{\frac{2\left(12\,\text{J} - 4\,\text{J}\right)}{4\,\text{kg}}} = \boxed{2.00\,\text{m/s}}$$

70 ••

Picture the Problem F_x is defined to be the negative of the derivative of the potential function with respect to x, that is $F_x = -dU/dx$. Consequently, given F as a function of x, we can find U by integrating F_x with respect to x.

(*a*) Evaluate the negative of the integral of $F(x)$ with respect to x:

$$U(x) = -\int F(x) = -\int Ax^{-3}dx$$

$$= \frac{1}{2}\frac{A}{x^2} + U_0$$

where U_0 is a constant whose value is determined by conditions on $U(x)$.

For $x > 0$:

$$\boxed{U \text{ decreases as } x \text{ increases}}$$

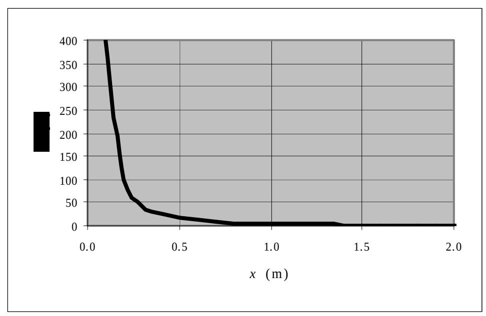
(*b*) As $x \to \infty$, $\frac{1}{2}\frac{A}{x^2} \to 0$:

$\therefore\ U_0 = 0$

and

$$U(x) = \frac{1}{2}\frac{A}{x^2} = \frac{1}{2}\frac{8\,\text{N}\cdot\text{m}^3}{x^2} = \boxed{\frac{4}{x^2}\,\text{N}\cdot\text{m}^3}$$

(*c*) The graph of $U(x)$ is shown to the right:



***71** •••

Picture the Problem Let L be the total length of one cable and the zero of gravitational potential energy be at the top of the pulleys. We can find the value of y for which the potential energy of the system is an extremum by differentiating $U(y)$ with respect to y and setting this derivative equal to zero. We can establish that this value corresponds to a minimum by evaluating the second derivative of $U(y)$ at the point identified by the first derivative. We can apply Newton's 2nd law to the clock to confirm the result we obtain by examining the derivatives of $U(y)$.

(*a*) Express the potential energy of the system as the sum of the potential energies of the clock and counterweights:

$$U(y) = U_{\text{clock}}(y) + U_{\text{weights}}(y)$$

Substitute to obtain:

$$U(y) = \boxed{-mgy - 2Mg\left(L - \sqrt{y^2 + d^2}\right)}$$

(*b*) Differentiate *U*(*y*) with respect to *y*:

$$\frac{dU(y)}{dy}=-\frac{d}{dy}\left[mgy+2Mg\left(L-\sqrt{y^2+d^2}\right)\right]$$

$$=-\left[mg-2Mg\frac{y}{\sqrt{y^2+d^2}}\right]$$

or

$$mg-2Mg\frac{y'}{\sqrt{y'^2+d^2}}=0 \text{ for extrema}$$

Solve for *y*′ to obtain:

$$y'=d\sqrt{\frac{m^2}{4M^2-m^2}}$$

Find $\frac{d^2U(y)}{dy^2}$:

$$\frac{d^2U(y)}{dy^2}=-\frac{d}{dy}\left[mg-2Mg\frac{y}{\sqrt{y^2+d^2}}\right]$$

$$=\frac{2Mgd^2}{\left(y^2+d^2\right)^{3/2}}$$

Evaluate $\frac{d^2U(y)}{dy^2}$ at $y=y'$:

$$\left.\frac{d^2U(y)}{dy^2}\right|_{y'}=\left.\frac{2Mgd^2}{\left(y^2+d^2\right)^{3/2}}\right|_{y'}$$

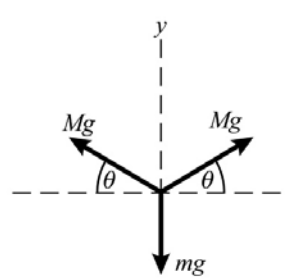
$$=\frac{2Mgd}{\left(\frac{m^2}{4M^2-m^2}+1\right)^{3/2}}$$

$$>0$$

and the potential energy is a minimum at

$$y=\boxed{d\sqrt{\frac{m^2}{4M^2-m^2}}}$$

(*c*) The FBD for the clock is shown to the right:



Apply $\sum F_y=0$ to the clock:

$$2Mg\sin\theta-mg=0$$

and

$$\sin\theta=\frac{m}{2M}$$

Express $\sin\theta$ in terms of y and d:

$$\sin\theta = \frac{y}{\sqrt{y^2 + d^2}}$$

Substitute to obtain:

$$\boxed{\frac{m}{2M} = \frac{y}{\sqrt{y^2 + d^2}}}$$

which is equivalent to the first equation in part (*b*).

This is a point of stable equilibrium. If the clock is displaced downward, θ increases, leading to a larger upward force on the clock. Similarly, if the clock is displaced upward, the net force from the cables decreases. Because of this, the clock will be pulled back toward the equilibrium point if it is displaced away from it.

Remarks: Because we've shown that the potential energy of the system is a minimum at $y = y'$ (i.e., $U(y)$ is concave upward at that point), we can conclude that this point is one of stable equilibrium.

General Problems

***72** •

Picture the Problem 25 percent of the electrical energy generated is to be diverted to do the work required to change the potential energy of the American people. We can calculate the height to which they can be lifted by equating the change in potential energy to the available energy.

Express the change in potential energy of the population of the United States in this process:

$$\Delta U = Nmgh$$

Letting E represent the total energy generated in February 2002, relate the change in potential to the energy available to operate the elevator:

$$Nmgh = 0.25E$$

Solve for h:

$$h = \frac{0.25E}{Nmg}$$

Substitute numerical values and evaluate h:

$$h = \frac{(0.25)(60.7\times10^{9}\ \text{kW}\cdot\text{h})\left(\frac{3600\,\text{s}}{1\,\text{h}}\right)}{(287\times10^{6})(60\,\text{kg})(9.81\,\text{m/s}^2)} = \boxed{323\,\text{km}}$$

73 •

Picture the Problem We can use the definition of the work done in changing the potential energy of a system and the definition of power to solve this problem.

(*a*) Find the work done by the crane in changing the potential energy of its load:

$$W = mgh = (6\times10^{6}\ \text{kg})\,(9.81\ \text{m/s}^2)\,(12\ \text{m}) = \boxed{706\,\text{MJ}}$$

(*b*) Use the definition of power to find the power developed by the crane:

$$P \equiv \frac{dW}{dt} = \frac{706\,\text{MJ}}{60\,\text{s}} = \boxed{11.8\,\text{MW}}$$

74 •

Picture the Problem The power P of the engine needed to operate this ski lift is related to the rate at which it changes the potential energy U of the cargo of the gondolas according to $P = \Delta U/\Delta t$. Because as many empty gondolas are descending as are ascending, we do not need to know their mass.

Express the rate at which work is done as the cars are lifted:

$$P = \frac{\Delta U}{\Delta t}$$

Letting N represent the number of gondola cars and M the mass of each, express the change in U as they are lifted a vertical displacement Δh:

$$\Delta U = NMg\Delta h$$

Substitute to obtain:

$$P \equiv \frac{\Delta U}{\Delta t} = \frac{NMg\Delta h}{\Delta t}$$

Relate Δh to the angle of ascent θ and the length L of the ski lift:

$$\Delta h = L\sin\theta$$

Substitute for Δh in the expression for P:

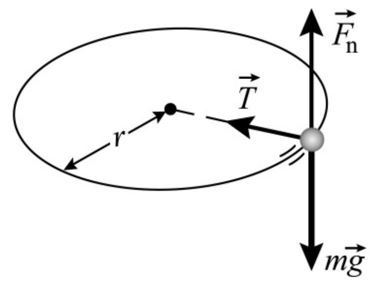
$$P = \frac{NMgL\sin\theta}{\Delta t}$$

Substitute numerical values and evaluate P:

$$P = \frac{12(550\,\text{kg})(9.81\,\text{m/s}^2)(5.6\,\text{km})\sin 30°}{(60\,\text{min})(60\,\text{s/min})} = \boxed{50.4\,\text{kW}}$$

75 •

Picture the Problem The application of Newton's 2nd law to the forces shown in the free-body diagram will allow us to relate R to T. The unknown mass and speed of the object can be eliminated by introducing its kinetic energy.



Apply $\sum F_{\text{radial}} = ma_{\text{radial}}$ the object and solve for R:

$$T = \frac{mv^2}{R} \text{ and } R = \frac{mv^2}{T}$$

Express the kinetic energy of the object:

$$K = \tfrac{1}{2}mv^2$$

Eliminate mv^2 between the two equations to obtain:

$$R = \frac{2K}{T}$$

Substitute numerical values and evaluate R:

$$R = \frac{2(90\,\text{J})}{360\,\text{N}} = \boxed{0.500\,\text{m}}$$

***76** •

Picture the Problem We can solve this problem by equating the expression for the gravitational potential energy of the elevated car and its kinetic energy when it hits the ground.

Express the gravitational potential energy of the car when it is at a distance h above the ground:

$$U = mgh$$

Express the kinetic energy of the car when it is about to hit the ground:

$$K = \tfrac{1}{2}mv^2$$

Equate these two expressions (because at impact, all the potential energy has been converted to kinetic energy) and solve for h:

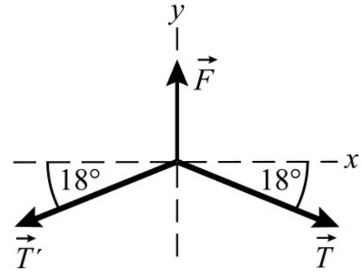
$$h = \frac{v^2}{2g}$$

Substitute numerical values and evaluate h:

$$h = \frac{\left[(100\,\text{km/h})(1\,\text{h}/3600\,\text{s})\right]^2}{2(9.81\,\text{m/s}^2)} = \boxed{39.3\,\text{m}}$$

77 •••

Picture the Problem The free-body diagram shows the forces acting on one of the strings at the bridge. The force whose magnitude is F is one-fourth of the force (103 N) the bridge exerts on the strings. We can apply the condition for equilibrium in the y direction to find the tension in each string. Repeating this procedure at the site of the plucking will yield the restoring force acting on the string. We can find the work done on the string as it returns to equilibrium from the product of the average force acting on it and its displacement.



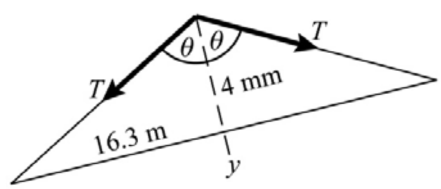
(a) Noting that, due to symmetry, $T' = T$, apply $\sum F_y = 0$ to the string at the point of contact with the bridge:

$$F - 2T\sin 18° = 0$$

Solve for and evaluate T:

$$T = \frac{F}{2\sin 18°} = \frac{\frac{1}{4}(103\,\text{N})}{2\sin 18°} = \boxed{41.7\,\text{N}}$$

(b) A free-body diagram showing the forces restoring the string to its equilibrium position just after it has been plucked is shown to the right:



Express the net force acting on the string immediately after it is released:

$$F_{\text{net}} = 2T\cos\theta$$

Use trigonometry to find θ:

$$\theta = \tan^{-1}\left(\frac{16.3\,\text{cm}}{4\,\text{mm}} \times \frac{10\,\text{mm}}{\text{cm}}\right) = 88.6°$$

Substitute and evaluate F_{net}:

$$F_{\text{net}} = 2(34.4\,\text{N})\cos 88.6° = \boxed{1.68\,\text{N}}$$

(c) Express the work done on the string in displacing it a distance dx':

$$dW = F dx'$$

If we pull the string out a distance x', the magnitude of the force pulling it down is approximately:

$$F = (2T)\frac{x'}{L/2} = \frac{4T}{L}x'$$

Substitute to obtain:

$$dW = \frac{4T}{L}x'\,dx'$$

Integrate to obtain:

$$W = \frac{4T}{L}\int_0^x x'dx' = \frac{2T}{L}x^2$$

where x is the final displacement of the string.

Substitute numerical values to obtain:

$$W = \frac{2(41.7\ \text{N})}{32.6\times10^{-2}\ \text{m}}\left(4\times10^{-3}\ \text{m}\right)^2 = \boxed{4.09\ \text{mJ}}$$

78 ••

Picture the Problem F_x is defined to be the negative of the derivative of the potential function with respect to x, that is $F_x = -dU/dx$. Consequently, given F as a function of x, we can find U by integrating F_x with respect to x.

Evaluate the integral of F_x with respect to x:

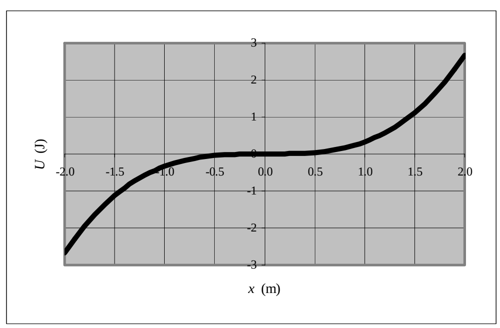
$$U(x) = -\int F(x)dx = -\int\left(-ax^2\right)dx = \tfrac{1}{3}ax^3 + U_0$$

Apply the condition that $U(0) = 0$ to determine U_0:

$U(0) = 0 + U_0 = 0 \Rightarrow U_0 = 0$

$$\therefore U(x) = \boxed{\tfrac{1}{3}ax^3}$$

The graph of $U(x)$ is shown to the right:



***79 ••**

Picture the Problem We can use the definition of work to obtain an expression for the position-dependent force acting on the cart. The work done on the cart can be calculated from its change in kinetic energy.

(*a*) Express the force acting on the cart in terms of the work done on it:

$$F(x)=\frac{dW}{dx}$$

Because *U* is constant:

$$F(x)=\frac{d}{dx}\left(\tfrac{1}{2}mv^2\right)=\frac{d}{dx}\left[\tfrac{1}{2}m(Cx)^2\right]=\boxed{mC^2x}$$

(*b*) The work done by this force changes the kinetic energy of the cart:

$$W=\Delta K=\tfrac{1}{2}mv_1^2-\tfrac{1}{2}mv_0^2=\tfrac{1}{2}mv_1^2-0=\tfrac{1}{2}m(Cx_1)^2=\boxed{\tfrac{1}{2}mC^2x_1^2}$$

80 ••

Picture the Problem The work done by $\vec{F}$ depends on whether it causes a displacement in the direction it acts.

(*a*) Because $\vec{F}$ is along *x*-axis and the displacement is along *y*-axis:

$$W=\int\vec{F}\cdot d\vec{s}=\boxed{0}$$

(*b*) Calculate the work done by $\vec{F}$ during the displacement from x = 2 m to 5 m:

$$W=\int\vec{F}\cdot d\vec{s}=\int_{2\,\text{m}}^{5\,\text{m}}\left(2\,\text{N/m}^2\right)x^2dx=\left(2\,\text{N/m}^2\right)\left[\frac{x^3}{3}\right]_{2\,\text{m}}^{5\,\text{m}}=\boxed{78.0\,\text{J}}$$

81 ••

Picture the Problem The velocity and acceleration of the particle can be found by differentiation. The power delivered to the particle can be expressed as the product of its velocity and the net force acting on it, and the work done by the force and can be found from the change in kinetic energy this work causes.

In the following, if *t* is in seconds and *m* is in kilograms, then *v* is in m/s, *a* is in m/s^2, *P* is in W, and *W* is in J.

(*a*) The velocity of the particle is given by:

$$v=\frac{dx}{dt}=\frac{d}{dt}\left(2t^3-4t^2\right)=\boxed{\left(6t^2-8t\right)}$$

The acceleration of the particle is given by:

$$a=\frac{dv}{dt}=\frac{d}{dt}\left(6t^2-8t\right)=\boxed{\left(12t-8\right)}$$

(*b*) Express and evaluate the rate at which energy is delivered to this particle as it accelerates:

$$P = Fv = mav = m(12t-8)\left(6t^2-8t\right)=\boxed{8mt\left(9t^2-18t+8\right)}$$

(*c*) Because the particle is moving in such a way that its potential energy is not changing, the work done by the force acting on the particle equals the change in its kinetic energy:

$$W=\Delta K=K_1-K_0=\tfrac{1}{2}m\left[\left(v(t_1)\right)^2-\left(v(0)\right)^2\right]=\tfrac{1}{2}m\left[\left(6t_1^2-8t_1\right)\right]^2-0=\boxed{2mt_1^2\left(3t_1-4\right)^2}$$

Remarks: We could also find *W* by integrating *P*(*t*) with respect to time.

82 ••

Picture the Problem We can calculate the work done by the given force from its definition. The power can be determined from $P=\vec{F}\cdot\vec{v}$ and v from the change in kinetic energy of the particle produced by the work done on it.

(*a*) Calculate the work done from its definition:

$$W=\int\vec{F}\cdot d\vec{s}=\int_0^{3\,\text{m}}\left(6+4x-3x^2\right)dx=\left[6x+\frac{4x^2}{2}-\frac{3x^3}{3}\right]_0^{3\,\text{m}}=\boxed{9.00\ \text{J}}$$

(*b*) Express the power delivered to the particle in terms of $F_{x=3\,\text{m}}$ and its velocity:

$$P=\vec{F}\cdot\vec{v}=F_{x=3\,\text{m}}v$$

Relate the work done on the particle to its kinetic energy and solve for its velocity:

$$W=\Delta K=K_{\text{final}}=\tfrac{1}{2}mv^2\ \text{since}\ v_0=0$$

Solve for and evaluate v:

$$v = \sqrt{\frac{2K}{m}} = \sqrt{\frac{2(9\,\text{J})}{3\,\text{kg}}} = 2.45\,\text{m/s}$$

Evaluate $F_{x=3\text{ m}}$:

$$F_{x=3\text{m}} = 6 + 4(3) - 3(3)^2 = -9\,\text{N}$$

Substitute for $F_{x=3\text{ m}}$ and v:

$$P = (-9\,\text{N})(2.45\,\text{m/s}) = \boxed{-22.1\,\text{W}}$$

***83 ••**

Picture the Problem We'll assume that the firing height is negligible and that the bullet lands at the same elevation from which it was fired. We can use the equation $R = \left(v_0^2/g\right)\sin 2\theta$ to find the range of the bullet and constant-acceleration equations to find its maximum height. The bullet's initial speed can be determined from its initial kinetic energy.

Express the range of the bullet as a function of its firing speed and angle of firing:

$$R = \frac{v_0^2}{g}\sin 2\theta$$

Rewrite the range equation using the trigonometric identity $\sin 2\theta = 2\sin\theta\cos\theta$:

$$R = \frac{v_0^2 \sin 2\theta}{g} = \frac{2v_0^2 \sin\theta\cos\theta}{g}$$

Express the position coordinates of the projectile along its flight path in terms of the parameter t:

$$x = (v_0\cos\theta)t$$

and

$$y = (v_0\sin\theta)t - \tfrac{1}{2}gt^2$$

Eliminate the parameter t and make use of the fact that the maximum height occurs when the projectile is at half the range to obtain:

$$h = \frac{(v_0\sin\theta)^2}{2g}$$

Equate R and h and solve the resulting equation for θ:

$$\tan\theta = 4 \Rightarrow \theta = \tan^{-1}4 = 76.0°$$

Relate the bullet's kinetic energy to its mass and speed and solve for the square of its speed:

$$K = \tfrac{1}{2}mv_0^2 \text{ and } v_0^2 = \frac{2K}{m}$$

Substitute for v_0^2 and θ and evaluate R:

$$R = \frac{2(1200\,\text{J})}{(0.02\,\text{kg})(9.81\,\text{m/s}^2)}\sin 2(76°) = \boxed{5.74\,\text{km}}$$

84 ••

Picture the Problem The work done on the particle is the area under the force-versus-displacement curve. Note that for negative displacements, F is positive, so W is negative for $x < 0$.

(*a*) Use either the formulas for the areas of simple geometric figures *or* counting squares and multiplying by the work represented by one square to complete the table to the right:

x	W

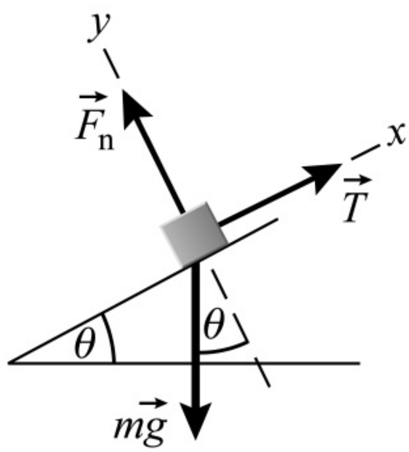
86 ••

Picture the Problem The pictorial representation shows the box at its initial position 0 at the bottom of the inclined plane and later at position 1. We'll assume that the block is at position 0. Because the surface is frictionless, the work done by the tension will change both the potential and kinetic energy of the block. We'll use Newton's 2nd law to find the acceleration of the block up the incline and a constant-acceleration equation to express v in terms of T, x, M, and θ. Finally, we can express the power produced by the tension in terms of the tension and the speed of the box.



(*a*) Use the definition of work to express the work the tension T does moving the box a distance x up the incline:

$$W = \boxed{Tx}$$

(*b*) Apply $\sum F_x = Ma_x$ to the box:

$$T - Mg\sin\theta = Ma_x$$

Solve for a_x:

$$a_x = \frac{T - Mg\sin\theta}{M} = \frac{T}{M} - g\sin\theta$$

Using a constant-acceleration equation, express the speed of the box in terms of its acceleration and the distance x it has moved up the incline:

$$v^2 = v_0^2 + 2a_x x$$

or, because $v_0 = 0$,

$$v = \sqrt{2a_x x}$$

Substitute for a_x to obtain:

$$v = \boxed{\sqrt{2\left(\frac{T}{M} - g\sin\theta\right)x}}$$

(*c*) The power produced by the tension in the string is given by:

$$P = Tv = \boxed{T\sqrt{2\left(\frac{T}{M} - g\sin\theta\right)x}}$$

87 •••

Picture the Problem We can use the definition of the magnitude of vector to show that the magnitude of $\vec{F}$ is F_0 and the definition of the scalar product to show that its direction is perpendicular to $\vec{r}$. The work done as the particle moves in a circular path can be found from its definition.

(*a*) Express the magnitude of $\vec{F}$:

$$\left|\vec{F}\right| = \sqrt{F_x^2 + F_y^2} = \sqrt{\left(\frac{F_0}{r}y\right)^2 + \left(-\frac{F_0}{r}x\right)^2} = \frac{F_0}{r}\sqrt{x^2 + y^2}$$

Because $r = \sqrt{x^2 + y^2}$:

$$\left|\vec{F}\right| = \frac{F_0}{r}\sqrt{x^2 + y^2} = \frac{F_0}{r}r = \boxed{F_0}$$

Form the scalar product of $\vec{F}$ and $\vec{r}$:

$$\vec{F}\cdot\vec{r} = \left(\frac{F_0}{r}\right)\left(y\,\hat{i} - x\,\hat{j}\right)\cdot\left(x\,\hat{i} + y\,\hat{j}\right) = \left(\frac{F_0}{r}\right)\left(xy - xy\right) = 0$$

Because $\vec{F}\cdot\vec{r} = 0$, $\boxed{\vec{F}\perp\vec{r}}$

(*b*) Because $\vec{F}\perp\vec{r}$, $\vec{F}$ is tangential to the circle and constant. At (5 m, 0), $\vec{F}$ points in the $-\hat{j}$ direction. If $d\vec{s}$ is in the $-\hat{j}$ direction, $dW > 0$. The work it does in one revolution is:

$$W = F_0(2\pi r) = 2\pi(5\,\mathrm{m})F_0 = (10\pi\,\mathrm{m})F_0 \text{ if the rotation is clockwise}$$

and

$$W = (-10\pi\,\mathrm{m})F_0 \text{ if the rotation is counterclockwise.}$$

$$\boxed{W = (10\pi\,\mathrm{m})F_0 \text{ if the rotation is clockwise}, -(10\pi\,\mathrm{m})F_0 \text{ if the rotation is counterclockwise. Because } W \neq 0 \text{ for a complete circuit, } \vec{F} \text{ is not conservative.}}$$

***88** •••

Picture the Problem We can substitute for r and $x\hat{i} + y\hat{j}$ in $\vec{F}$ to show that the magnitude of the force varies as the inverse of the square of the distance to the origin, and that its direction is opposite to the radius vector. We can find the work done by this force by evaluating the integral of F with respect to x from an initial position $x = 2$ m, $y = 0$ m to a final position $x = 5$ m, $y = 0$ m. Finally, we can apply Newton's 2nd law to the particle to relate its speed to its radius, mass, and the constant b.

(*a*) Substitute for *r* and $x\hat{\boldsymbol{i}} + y\hat{\boldsymbol{j}}$ in $\vec{F}$ to obtain:

$$\vec{F} = -\left(\frac{b}{\left(x^2 + y^2\right)^{3/2}}\right)\sqrt{x^2 + y^2}\,\hat{\boldsymbol{r}}$$

where $\hat{\boldsymbol{r}}$ is a unit vector pointing from the origin toward the point of application of $\vec{F}$.

Simplify to obtain:

$$\vec{F} = -b\left(\frac{1}{x^2 + y^2}\right)\hat{\boldsymbol{r}} = \boxed{-\frac{b}{r^2}\hat{\boldsymbol{r}}}$$

i.e., the magnitude of the force varies as the inverse of the square of the distance to the origin, and its direction is antiparallel (opposite) to the radius vector $\vec{r} = x\hat{\boldsymbol{i}} + y\hat{\boldsymbol{j}}$.

(*b*) Find the work done by this force by evaluating the integral of *F* with respect to *x* from an initial position *x* = 2 m, *y* = 0 m to a final position *x* = 5 m, *y* = 0 m:

$$W = -\int_{2\,\text{m}}^{5\,\text{m}} \frac{b}{x'^2}dx' = b\left[\frac{1}{x'}\right]_{2\,\text{m}}^{5\,\text{m}}$$

$$= 3\,\text{N}\cdot\text{m}^2\left(\frac{1}{5\,\text{m}} - \frac{1}{2\,\text{m}}\right) = \boxed{-0.900\,\text{J}}$$

(*c*) $\boxed{\text{No work is done as the force is perpendicular to the velocity.}}$

(*d*) Because the particle is moving in a circle, the force on the particle must be supplying the centripetal acceleration keeping it moving in the circle. Apply $\sum F_r = ma_c$ to the particle:

$$\frac{b}{r^2} = m\frac{v^2}{r}$$

Solve for *v*:

$$v = \sqrt{\frac{b}{mr}}$$

Substitute numerical values and evaluate *v*:

$$v = \sqrt{\frac{3\,\text{N}\cdot\text{m}^2}{(2\,\text{kg})(7\,\text{m})}} = \boxed{0.463\,\text{m/s}}$$

89 •••

Picture the Problem A spreadsheet program to calculate the potential is shown below. The constants used in the potential function and the formula used to calculate the ″6-12″ potential are as follows:

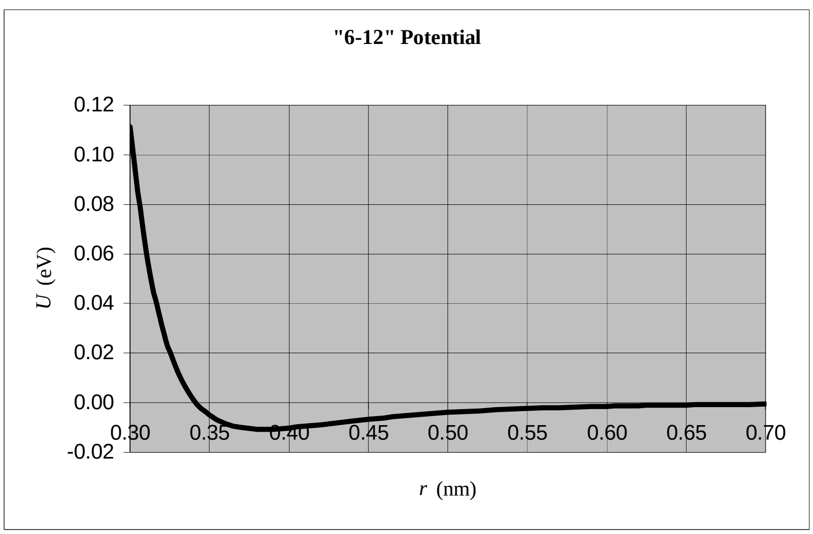
Cell	Content/Formula	Algebraic Form
B2	1.09×10^{-7}	*a*
B3	6.84×10^{-5}	*b*

D8	\$B\$2/C8^12–\$B\$3/C8^6	$\frac{a}{r^{12}} - \frac{b}{r^6}$
C9	C8+0.1	$r + \Delta r$

(*a*)

	A	B	C	D
1				
2	a =	1.09E-07		
3	b =	6.84E-05		
4				
5				
6				
7			*r*	*U*
8			3.00E-01	1.11E-01
9			3.10E-01	6.13E-02
10			3.20E-01	3.08E-02
11			3.30E-01	1.24E-02
12			3.40E-01	1.40E-03
13			3.50E-01	–4.95E-03
45			6.70E-01	–7.43E-04
46			6.80E-01	–6.81E-04
47			6.90E-01	–6.24E-04
48			7.00E-01	–5.74E-04

The graph shown below was generated from the data in the table shown above. Because the force between the atomic nuclei is given by $F = -(dU/dr)$, we can conclude that the shape of the potential energy function supports Feynman's claim.



(*b*) The minimum value is about –0.0107 eV, occurring at a separation of approximately 0.380 nm. Because the function is concave upward (a potential ″well″) at this separation, this separation is one of stable equilibrium, although very shallow.

(*c*) Relate the force of attraction between two argon atoms to the slope of the potential energy function:

$$F = -\frac{dU}{dr} = -\frac{d}{dr}\left[\frac{a}{r^{12}} - \frac{b}{r^6}\right] = \frac{12a}{r^{13}} - \frac{6b}{r^7}$$

Substitute numerical values and evaluate *F*(5 Å):

$$F = \frac{12\left(1.09\times10^{-7}\right)}{(0.5\,\text{nm})^{13}} - \frac{6\left(6.84\times10^{-5}\right)}{(0.5\,\text{nm})^{7}} = -4.18\times10^{-2}\,\frac{\text{eV}}{\text{nm}}\times\frac{1.6\times10^{-19}\,\text{J}}{\text{eV}}\times\frac{1\,\text{nm}}{10^{-9}\,\text{m}}$$
$$= \boxed{-6.69\times10^{-12}\,\text{N}}$$

where the minus sign means that the force is attractive.

Substitute numerical values and evaluate *F*(3.5 Å):

$$F = \frac{12\left(1.09\times10^{-7}\right)}{(0.35\,\text{nm})^{13}} - \frac{6\left(6.84\times10^{-5}\right)}{(0.35\,\text{nm})^{7}} = 4.68\times10^{-1}\,\frac{\text{eV}}{\text{nm}}\times\frac{1.6\times10^{-19}\,\text{J}}{\text{eV}}\times\frac{1\,\text{nm}}{10^{-9}\,\text{m}}$$
$$= \boxed{7.49\times10^{-11}\,\text{N}}$$

where the plus sign means that the force is repulsive.

***90** •••

Picture the Problem A spreadsheet program to plot the Yukawa potential is shown below. The constants used in the potential function and the formula used to calculate the Yukawa potential are as follows:

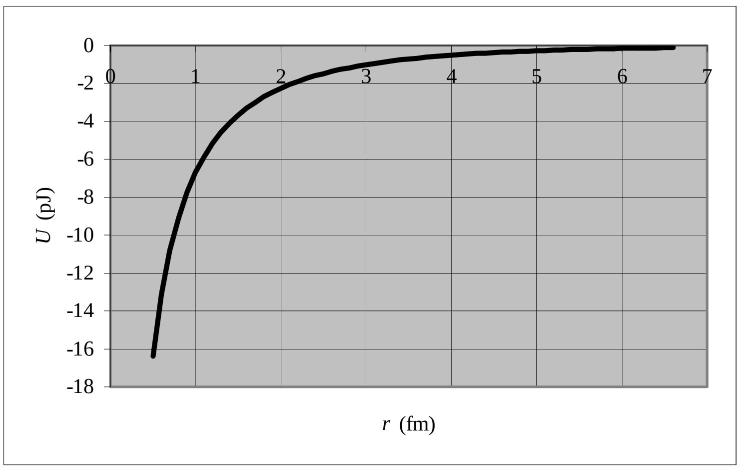
Cell	Content/Formula	Algebraic Form
B1	4	U_0
B2	2.5	a
D8	–$B$1*($B$2/C9)*EXP(–C9/$B$2)	$-U_0\left(\frac{a}{r}\right)e^{-r/a}$
C10	C9+0.1	$r+\Delta r$

(*a*)

	A	B	C	D
1	U0=	4	pJ	
2	a=	2.5	fm	
3				
7				
8			r	U
9			0.5	–16.37
10			0.6	–13.11

11			0.7	–10.80
12			0.8	–9.08
13			0.9	–7.75
14			1	–6.70
64			6	–0.15
65			6.1	–0.14
66			6.2	–0.14
67			6.3	–0.13
68			6.4	–0.12
69			6.5	–0.11
70			6.6	–0.11

U as a function of *r* is shown below.



(*b*) Relate the force between the nucleons to the slope of the potential energy function:

$$F(r) = -\frac{dU(r)}{dr}$$

$$= -\frac{d}{dr}\left[-U_0\left(\frac{a}{r}\right)e^{-r/a}\right]$$

$$= \boxed{-U_0 e^{-r/a}\left(\frac{a}{r^2} + \frac{1}{r}\right)}$$

(*c*) Evaluate $F(2a)$:

$$F(2a) = -U_0 e^{-2a/a}\left(\frac{a}{(2a)^2} + \frac{1}{2a}\right)$$

$$= -U_0 e^{-2}\left(\frac{3}{4a}\right)$$

Evaluate $F(a)$:

$$F(a) = -U_0 e^{-a/a}\left(\frac{a}{(a)^2} + \frac{1}{a}\right)$$

$$= -U_0 e^{-1}\left(\frac{1}{a} + \frac{1}{a}\right) = -U_0 e^{-1}\left(\frac{2}{a}\right)$$

Express the ratio $F(2a)/F(a)$:

$$\frac{F(2a)}{F(a)} = \frac{-U_0 e^{-2}\left(\frac{3}{4a}\right)}{-U_0 e^{-1}\left(\frac{2}{a}\right)} = \frac{3}{8}e^{-1}$$

$$= \boxed{0.138}$$

(d) Evaluate $F(5a)$:

$$F(5a) = -U_0 e^{-5a/a}\left(\frac{a}{(5a)^2} + \frac{1}{5a}\right)$$

$$= -U_0 e^{-5}\left(\frac{6}{25a}\right)$$

Express the ratio $F(5a)/F(a)$:

$$\frac{F(5a)}{F(a)} = \frac{-U_0 e^{-5}\left(\frac{6}{25a}\right)}{-U_0 e^{-1}\left(\frac{2}{a}\right)} = \frac{3}{25}e^{-4}$$

$$= \boxed{2.20 \times 10^{-3}}$$

Chapter 7
Conservation of Energy

Conceptual Problems

***1** •

Determine the Concept Because the peg is frictionless, mechanical energy is conserved as this system evolves from one state to another. The system moves and so we know that $\Delta K > 0$. Because $\Delta K + \Delta U = constant$, $\Delta U < 0$. $\boxed{(a) \text{ is correct.}}$

2 •

Determine the Concept Choose the zero of gravitational potential energy to be at ground level. The two stones have the same initial energy because they are thrown from the same height with the same initial speeds. Therefore, they will have the same total energy at all times during their fall. When they strike the ground, their gravitational potential energies will be zero and their kinetic energies will be equal. Thus, their speeds at impact will be equal. The stone that is thrown at an angle of 30° above the horizontal has a longer flight time due to its initial upward velocity and so they do not strike the ground at the same time. $\boxed{(c) \text{ is correct.}}$

3 •

(*a*) False. Forces that are external to a system can do work on the system to change its energy.

(*b*) False. In order for some object to do work, it must exert a force *over some distance*. The chemical energy stored in the muscles of your legs allows your muscles to do the work that launches you into the air.

4 •

Determine the Concept Your kinetic energy increases at the expense of chemical energy.

***5** •

Determine the Concept As she starts pedaling, chemical energy inside her body is converted into kinetic energy as the bike picks up speed. As she rides it up the hill, chemical energy is converted into gravitational potential and thermal energy. While freewheeling down the hill, potential energy is converted to kinetic energy, and while braking to a stop, kinetic energy is converted into thermal energy (a more random form of kinetic energy) by the frictional forces acting on the bike.

***6** •

Determine the Concept If we define the system to include the falling body and the earth, then no work is done by an external agent and $\Delta K + \Delta U_g + \Delta E_{therm} = 0$. Solving for the change in the gravitational potential energy we find $\Delta U_g = -(\Delta K + \text{friction energy})$.

$\boxed{(b) \text{ is correct.}}$

7 ••

Picture the Problem Because the constant friction force is responsible for a constant acceleration, we can apply the constant-acceleration equations to the analysis of these statements. We can also apply the work-energy theorem with friction to obtain expressions for the kinetic energy of the car and the rate at which it is changing. Choose the system to include the earth and car and assume that the car is moving on a horizontal surface so that $\Delta U = 0$.

(*a*) A constant frictional force causes a constant acceleration. The stopping distance of the car is related to its speed before the brakes were applied through a constant-acceleration equation.

$$v^2 = v_0^2 + 2a\Delta s \text{ where } v = 0.$$

$$\therefore \Delta s = \frac{-v_0^2}{2a} \text{ where } a < 0.$$

Thus, $\Delta s \propto v_0^2$ and statement (*a*) is *false*.

(*b*) Apply the work-energy theorem with friction to obtain:

$$\Delta K = -W_{\text{f}} = -\mu_{\text{k}} mg\Delta s$$

Express the rate at which K is dissipated:

$$\frac{\Delta K}{\Delta t} = -\mu_{\text{k}} mg \frac{\Delta s}{\Delta t}$$

Thus, $\dfrac{\Delta K}{\Delta t} \propto v$ and therefore not constant.

Statement (*b*) is *false*.

(*c*) In part (*b*) we saw that: $K \propto \Delta s$

Because $\Delta s \propto \Delta t$: $K \propto \Delta t$ and statement (*c*) is *false*.

Because none of the above are correct: $\boxed{(d) \text{ is correct.}}$

8 •

Picture the Problem We'll let the zero of potential energy be at the bottom of each ramp and the mass of the block be m. We can use conservation of energy to predict the speed of the block at the foot of each ramp. We'll consider the distance the block travels on each ramp, as well as its speed at the foot of the ramp, in deciding its descent times.

Use conservation of energy to find the speed of the blocks at the bottom of each ramp:

$$\Delta K + \Delta U = 0$$

or

$$K_{\text{bot}} - K_{\text{top}} + U_{\text{bot}} - U_{\text{top}} = 0$$

Because $K_{top} = U_{bot} = 0$: $K_{bot} - U_{top} = 0$

Substitute to obtain: $\frac{1}{2}mv_{bot}^2 - mgH = 0$

Solve for v_{bot}: $v_{bot} = \sqrt{2gH}$ independently of the shape of the ramp.

Because the block sliding down the circular arc travels a greater distance (an arc length is greater than the length of the chord it defines) but arrives at the bottom of the ramp with the same speed that it had at the bottom of the inclined plane, it will require more time to arrive at the bottom of the arc. $\boxed{(b)\text{ is correct.}}$

9 ••

Determine the Concept No. From the work-kinetic energy theorem, no total work is being done on the rock, as its kinetic energy is constant. However, the rod must exert a tangential force on the rock to keep the speed constant. The effect of this force is to cancel the component of the force of gravity that is tangential to the trajectory of the rock.

Estimation and Approximation

***10** ••

Picture the Problem We'll use the data for the "typical male" described above and assume that he spends 8 hours per day sleeping, 2 hours walking, 8 hours sitting, 1 hour in aerobic exercise, and 5 hours doing moderate physical activity. We can approximate his energy utilization using $E_{activity} = AP_{activity}\Delta t_{activity}$, where A is the surface area of his body, $P_{activity}$ is the rate of energy consumption in a given activity, and $\Delta t_{activity}$ is the time spent in the given activity. His total energy consumption will be the sum of the five terms corresponding to his daily activities.

(*a*) Express the energy consumption of the hypothetical male:

$$E = E_{sleeping} + E_{walking} + E_{sitting} + E_{mod.\,act.} + E_{aerobic\,act.}$$

Evaluate $E_{sleeping}$:

$$\begin{aligned} E_{sleeping} &= AP_{sleeping}\Delta t_{sleeping} \\ &= (2\,m^2)(40\,W/m^2)(8\,h)(3600\,s/h) \\ &= 2.30\times10^6\,J \end{aligned}$$

Evaluate $E_{walking}$:

$$\begin{aligned} E_{walking} &= AP_{walking}\Delta t_{walking} \\ &= (2\,m^2)(160\,W/m^2)(2\,h)(3600\,s/h) \\ &= 2.30\times10^6\,J \end{aligned}$$

Evaluate $E_{sitting}$:

$$\begin{aligned} E_{sitting} &= AP_{sitting}\Delta t_{sitting} \\ &= (2\,m^2)(60\,W/m^2)(8\,h)(3600\,s/h) \\ &= 3.46\times10^6\,J \end{aligned}$$

Evaluate $E_{\text{mod. act.}}$:

$$\begin{aligned} E_{\text{mod. act.}} &= AP_{\text{mod. act.}}\Delta t_{\text{mod. act.}} \\ &= \left(2\,\text{m}^2\right)\left(175\,\text{W/m}^2\right)\left(5\,\text{h}\right)\left(3600\,\text{s/h}\right) \\ &= 6.30\times10^6\ \text{J} \end{aligned}$$

Evaluate $E_{\text{aerobic act.}}$:

$$\begin{aligned} E_{\text{aerobic act.}} &= AP_{\text{aerobic act.}}\Delta t_{\text{aerobic act.}} \\ &= \left(2\,\text{m}^2\right)\left(300\,\text{W/m}^2\right)\left(1\,\text{h}\right)\left(3600\,\text{s/h}\right) \\ &= 2.16\times10^6\ \text{J} \end{aligned}$$

Substitute to obtain:

$$\begin{aligned} E &= 2.30\times10^6\ \text{J} + 2.30\times10^6\ \text{J} + 3.46\times10^6\ \text{J} \\ &\quad + 6.30\times10^6\ \text{J} + 2.16\times10^6\ \text{J} \\ &= \boxed{16.5\times10^6\ \text{J}} \end{aligned}$$

Express the average metabolic rate represented by this energy consumption:

$$P_{\text{av}} = \frac{E}{\Delta t} = \frac{16.5\times10^6\ \text{J}}{\left(24\,\text{h}\right)\left(3600\,\text{s/h}\right)} = \boxed{191\,\text{W}}$$

or about twice that of a 100 W light bulb.

(*b*) Express his average energy consumption in terms of kcal/day:

$$E = \frac{16.5\times10^6\ \text{J/day}}{4190\,\text{J/kcal}} = \boxed{3940\,\text{kcal/day}}$$

(*c*) $\dfrac{3940\,\text{kcal}}{175\,\text{lb}} = 22.5\,\text{kcal/lb}$ is higher than the estimate given in the statement of the problem. However, by adjusting the day's activities, the metabolic rate can vary by more than a factor of 2.

11 •

Picture the Problem The rate at which you expend energy, i.e., do work, is defined as *power* and is the ratio of the work done to the time required to do the work.

Relate the rate at which you can expend energy to the work done in running up the four flights of stairs and solve for your running time:

$$P = \frac{\Delta W}{\Delta t} \Rightarrow \Delta t = \frac{\Delta W}{P}$$

Express the work done in climbing the stairs:

$$\Delta W = mgh$$

Substitute for ΔW to obtain:

$$\Delta t = \frac{mgh}{P}$$

Assuming that your weight is 600 N, evaluate Δt:

$$\Delta t = \frac{(600\,\text{N})(4\times 3.5\,\text{m})}{250\,\text{W}} = \boxed{33.6\,\text{s}}$$

12 •

Picture the Problem The intrinsic rest energy in matter is related to the mass of matter through Einstein's equation $E_0 = mc^2$.

(*a*) Relate the rest mass consumed to the energy produced and solve for and evaluate *m*:

$$E_0 = mc^2 \Rightarrow m = \frac{E_0}{c^2} \qquad (1)$$

$$m = \frac{1\,\text{J}}{(2.998\times 10^8\,\text{m/s})^2} = \boxed{1.11\times 10^{-17}\,\text{kg}}$$

(*b*) Express the energy required as a function of the power of the light bulb and evaluate *E*:

$$\begin{aligned} E &= 3Pt \\ &= 3(100\,\text{W})(10\,\text{y}) \\ &\quad\times\left(\frac{365.24\,\text{d}}{\text{y}}\right)\left(\frac{24\,\text{h}}{\text{d}}\right)\left(\frac{3600\,\text{s}}{\text{h}}\right) \\ &= 9.47\times 10^{10}\,\text{J} \end{aligned}$$

Substitute in equation (1) to obtain:

$$m = \frac{9.47\times 10^{10}\,\text{J}}{(2.998\times 10^8\,\text{m/s})^2} = \boxed{1.05\,\mu\text{g}}$$

***13** •

Picture the Problem There are about 3×10^8 people in the United States. On the assumption that the average family has 4 people in it and that they own two cars, we have a total of 1.5×10^8 automobiles on the road (excluding those used for industry). We'll assume that each car uses about 15 gal of fuel per week.

Calculate, based on the assumptions identified above, the total annual consumption of energy derived from gasoline:

$$(1.5\times 10^8\,\text{auto})\left(15\frac{\text{gal}}{\text{auto}\cdot\text{week}}\right)\left(52\frac{\text{weeks}}{y}\right)\left(2.6\times 10^8\frac{\text{J}}{\text{gal}}\right) = \boxed{3.04\times 10^{19}\,\text{J/y}}$$

Express this rate of energy use as a fraction of the total annual energy use by the US:

$$\frac{3.04\times 10^{19}\,\text{J/y}}{5\times 10^{20}\,\text{J/y}} \approx \boxed{6\%}$$

Remarks: This is an average power expenditure of roughly $9\text{x}10^{11}$ watt, and a total cost (assuming $1.15 per gallon) of about 140 billion dollars per year.

14 •

Picture the Problem The energy consumption of the U.S. works out to an average power consumption of about 1.6×10^{13} watt. The solar constant is roughly 10^3 W/m^2 (reaching the ground), or about 120 W/m^2 of useful power with a 12% conversion efficiency. Letting P represent the daily rate of energy consumption, we can relate the power available at the surface of the earth to the required area of the solar panels using $P = IA$.

Relate the required area to the electrical energy to be generated by the solar panels:

$$P = IA$$

where I is the solar intensity that reaches the surface of the Earth.

Solve for and evaluate A:

$$A = \frac{P}{I} = \frac{2\left(1.6\times10^{13}\ \text{W}\right)}{120\,\text{W/m}^2}$$
$$= 2.67\times10^{11}\ \text{m}^2$$

where the factor of 2 comes from the fact that the sun is only up for roughly half the day.

Find the side of a square with this area:

$$s = \sqrt{2.67\times10^{11}\ \text{m}^2} = \boxed{516\,\text{km}}$$

Remarks: A more realistic estimate that would include the variation of sunlight over the day and account for latitude and weather variations might very well increase the area required by an order of magnitude.

15 •

Picture the Problem We can relate the energy available from the water in terms of its mass, the vertical distance it has fallen, and the efficiency of the process. Differentiation of this expression with respect to time will yield the rate at which water must pass through its turbines to generate Hoover Dam's annual energy output.

Assuming a total efficiency η, use the expression for the gravitational potential energy near the earth's surface to express the energy available from the water when it has fallen a distance h:

$$E = \eta mgh$$

Differentiate this expression with respect to time to obtain:

$$P = \frac{d}{dt}\left[\eta mgh\right] = \eta gh\frac{dm}{dt} = \eta\rho gh\frac{dV}{dt}$$

Solve for dV/dt:

$$\frac{dV}{dt} = \frac{P}{\eta\rho gh} \qquad (1)$$

Using its definition, relate the dam's annual power output to the energy produced:

$$P = \frac{\Delta E}{\Delta t}$$

Substitute numerical values to obtain:

$$P = \frac{4\times10^9\ \text{kW}\cdot\text{h}}{\left(365.24\,\text{d}\right)\left(24\,\text{h/d}\right)} = 4.57\times10^8\ \text{W}$$

Substitute in equation (1) and evaluate dV/dt:

$$\frac{dV}{dt} = \frac{4.57\times10^{8}\ \text{W}}{0.2(1\,\text{kg/L})(9.81\,\text{m/s}^2)(211\,\text{m})} = \boxed{1.10\times10^{6}\ \text{L/s}}$$

The Conservation of Mechanical Energy

16 •

Picture the Problem The work done in compressing the spring is stored in the spring as potential energy. When the block is released, the energy stored in the spring is transformed into the kinetic energy of the block. Equating these energies will give us a relationship between the compressions of the spring and the speeds of the blocks.

Let the numeral 1 refer to the first case and the numeral 2 to the second case. Relate the compression of the spring in the second case to its potential energy, which equals its initial kinetic energy when released:

$$\tfrac{1}{2}kx_2^2 = \tfrac{1}{2}m_2v_2^2 = \tfrac{1}{2}(4m_1)(3v_1)^2 = 18m_1v_1^2$$

Relate the compression of the spring in the first case to its potential energy, which equals its initial kinetic energy when released:

$$\tfrac{1}{2}kx_1^2 = \tfrac{1}{2}m_1v_1^2$$

or

$$m_1v_1^2 = kx_1^2$$

Substitute to obtain:

$$\tfrac{1}{2}kx_2^2 = 18kx_1^2$$

Solve for x_2:

$$x_2 = \boxed{6x_1}$$

17 •

Picture the Problem Choose the zero of gravitational potential energy to be at the foot of the hill. Then the kinetic energy of the woman on her bicycle at the foot of the hill is equal to her gravitational potential energy when she has reached her highest point on the hill.

Equate the kinetic energy of the rider at the foot of the incline and her gravitational potential energy when she has reached her highest point on the hill and solve for h:

$$\tfrac{1}{2}mv^2 = mgh \Rightarrow h = \frac{v^2}{2g}$$

Relate her displacement along the

$$d = h/\sin\theta$$

incline d to h and the angle of the incline:

Substitute for h to obtain:

$$d\sin\theta = \frac{v^2}{2g}$$

Solve for d:

$$d = \frac{v^2}{2g\sin\theta}$$

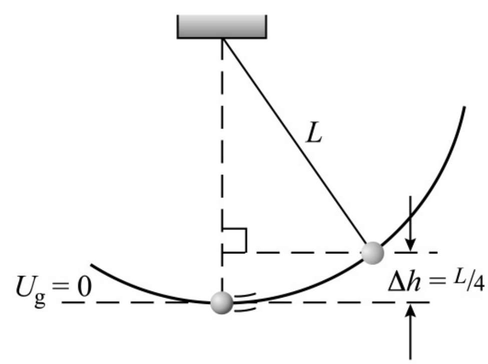
Substitute numerical values and evaluate d:

$$d = \frac{(10\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)\sin 3°} = 97.4\,\text{m}$$

and $\boxed{(c)\text{ is correct.}}$

***18** •

Picture the Problem The diagram shows the pendulum bob in its initial position. Let the zero of gravitational potential energy be at the low point of the pendulum's swing, the equilibrium position. We can find the speed of the bob at it passes through the equilibrium position by equating its initial potential energy to its kinetic energy as it passes through its lowest point.



Equate the initial gravitational potential energy and the kinetic energy of the bob as it passes through its lowest point and solve for v:

$$mg\Delta h = \tfrac{1}{2}mv^2$$

and

$$v = \sqrt{2g\Delta h}$$

Express Δh in terms of the length L of the pendulum:

$$\Delta h = \frac{L}{4}$$

Substitute and simplify:

$$v = \boxed{\sqrt{\frac{gL}{2}}}$$

19 •

Picture the Problem Choose the zero of gravitational potential energy to be at the foot of the ramp. Let the system consist of the block, the earth, and the ramp. Then there are no external forces acting on the system to change its energy and the kinetic energy of the block at the foot of the ramp is equal to its gravitational potential energy when it has reached its highest point.

Relate the gravitational potential energy of the block when it has reached *h*, its highest point on the ramp, to its kinetic energy at the foot of the ramp:

$$mgh = \tfrac{1}{2}mv^2$$

Solve for *h*:

$$h = \frac{v^2}{2g}$$

Relate the displacement *d* of the block along the ramp to *h* and the angle the ramp makes with the horizontal:

$$d = h/\sin\theta$$

Substitute for *h*:

$$d\sin\theta = \frac{v^2}{2g}$$

Solve for *d*:

$$d = \frac{v^2}{2g\sin\theta}$$

Substitute numerical values and evaluate *d*:

$$d = \frac{(7\ \text{m/s})^2}{2(9.81\ \text{m/s}^2)\sin 40°} = \boxed{3.89\ \text{m}}$$

20 •

Picture the Problem Let the system consist of the earth, the block, and the spring. With this choice there are no external forces doing work to change the energy of the system. Let $U_g = 0$ at the elevation of the spring. Then the initial gravitational potential energy of the 3-kg object is transformed into kinetic energy as it slides down the ramp and then, as it compresses the spring, into potential energy stored in the spring.

(*a*) Apply conservation of energy to relate the distance the spring is compressed to the initial potential energy of the block:

$$W_{ext} = \Delta K + \Delta U = 0$$

and, because $\Delta K = 0$,

$$-mgh + \tfrac{1}{2}kx^2 = 0$$

Solve for *x*:

$$x = \sqrt{\frac{2mgh}{k}}$$

Substitute numerical values and evaluate x:

$$x=\sqrt{\frac{2(3\,\text{kg})(9.81\,\text{m/s}^2)(5\,\text{m})}{400\,\text{N/m}}}=\boxed{0.858\,\text{m}}$$

(b) The energy stored in the compressed spring will accelerate the block, launching it back up the incline:

The block will retrace its path, rising to a height of 5 m.

21 •

Picture the Problem With U_g chosen to be zero at the uncompressed level of the spring, the ball's initial gravitational potential energy is negative. The difference between the initial potential energy of the spring and the gravitational potential energy of the ball is first converted into the kinetic energy of the ball and then into gravitational potential energy as the ball rises and slows … eventually coming momentarily to rest.

Apply the conservation of energy to the system as it evolves from its initial to its final state:

$$-mgx+\tfrac{1}{2}kx^2=mgh$$

Solve for h:

$$h=\frac{kx^2}{2mg}-x$$

Substitute numerical values and evaluate h:

$$h=\frac{(600\,\text{N/m})(0.05\,\text{m})^2}{2(0.015\,\text{kg})(9.81\,\text{m/s}^2)}-0.05\,\text{m}=\boxed{5.05\,\text{m}}$$

22 •

Picture the Problem Let the system include the earth and the container. Then the work done by the crane is done by an external force and this work changes the energy of the system. Because the initial and final speeds of the container are zero, the initial and final kinetic energies are zero and the work done by the crane equals the change in the gravitational potential energy of the container. Choose $U_g = 0$ to be at the level of the deck of the freighter.

Apply conservation of energy to the system:

$$W_{ext}=\Delta E_{sys}=\Delta K+\Delta U$$

Because $\Delta K = 0$:

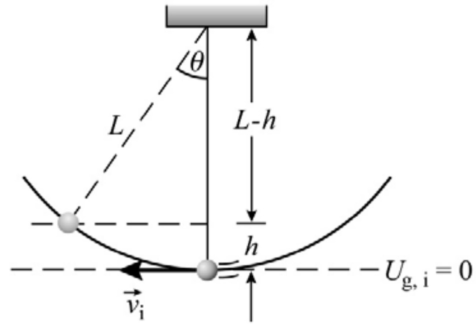
$$W_{ext}=\Delta U=mg\Delta h$$

Evaluate the work done by the crane:

$$W_{ext} = mg\Delta h = (4000\,\text{kg})(9.81\,\text{m/s}^2)(-8\,\text{m}) = \boxed{-314\,\text{kJ}}$$

23 •

Picture the Problem Let the system consist of the earth and the child. Then $W_{ext} = 0$. Choose $U_{g,i} = 0$ at the child's lowest point as shown in the diagram to the right. Then the child's initial energy is entirely kinetic and its energy when it is at its highest point is entirely gravitational potential. We can determine h from energy conservation and then use trigonometry to determine θ.



Using the diagram, relate θ to h and L:

$$\theta = \cos^{-1}\left(\frac{L-h}{L}\right) = \cos^{-1}\left(1-\frac{h}{L}\right)$$

Apply conservation of energy to the system to obtain:

$$\tfrac{1}{2}mv_i^2 - mgh = 0$$

Solve for h:

$$h = \frac{v_i^2}{2g}$$

Substitute to obtain:

$$\theta = \cos^{-1}\left(1-\frac{v_i^2}{2gL}\right)$$

Substitute numerical values and evaluate θ:

$$\theta = \cos^{-1}\left(1-\frac{(3.4\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)(6\,\text{m})}\right) = \boxed{25.6°}$$

***24** ••

Picture the Problem Let the system include the two objects and the earth. Then $W_{ext} = 0$. Choose $U_g = 0$ at the elevation at which the two objects meet. With this choice, the initial potential energy of the 3-kg object is positive and that of the 2-kg object is negative. Their sum, however, is positive. Given our choice for $U_g = 0$, this initial potential energy is transformed entirely into kinetic energy.

Apply conservation of energy:

$$W_{ext} = \Delta K + \Delta U_g = 0$$

or, because $W_{ext} = 0$,

$$\Delta K = -\Delta U_g$$

Substitute for ΔK and solve for v_f; noting that m represents the sum of the masses of the objects as they are both moving in the final state:

$$\tfrac{1}{2}mv_f^2 - \tfrac{1}{2}mv_i^2 = -\Delta U_g$$

or, because $v_i = 0$,

$$v_f = \sqrt{\frac{-2\Delta U_g}{m}}$$

Express and evaluate ΔU_g:

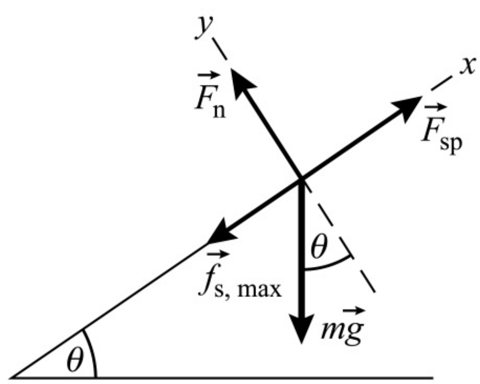
$$\begin{aligned}\Delta U_g &= U_{g,f} - U_{g,i} \\ &= 0 - (3\,\text{kg} - 2\,\text{kg})(0.5\,\text{m}) \\ &\quad \times (9.81\,\text{m/s}^2) \\ &= -4.91\,\text{J}\end{aligned}$$

Substitute and evaluate v_f:

$$v_f = \sqrt{\frac{-2(-4.91\,\text{J})}{5\,\text{kg}}} = \boxed{1.40\,\text{m/s}}$$

25 ••

Picture the Problem The free-body diagram shows the forces acting on the block when it is about to move. F_{sp} is the force exerted by the spring and, because the block is on the verge of sliding, $f_s = f_{s,max}$. We can use Newton's 2nd law, under equilibrium conditions, to express the elongation of the spring as a function of m, k and θ and then substitute in the expression for the potential energy stored in a stretched or compressed spring.



Express the potential energy of the spring when the block is about to move:

$$U = \tfrac{1}{2}kx^2$$

Apply $\sum \vec{F} = m\vec{a}$, under equilibrium conditions, to the block:

$$\sum F_x = F_{sp} - f_{s,max} - mg\sin\theta = 0$$

and

$$\sum F_y = F_n - mg\cos\theta = 0$$

Using $f_{s,max} = \mu_s F_n$ and $F_{sp} = kx$, eliminate $f_{s,max}$ and F_{sp} from the x equation and solve for x:

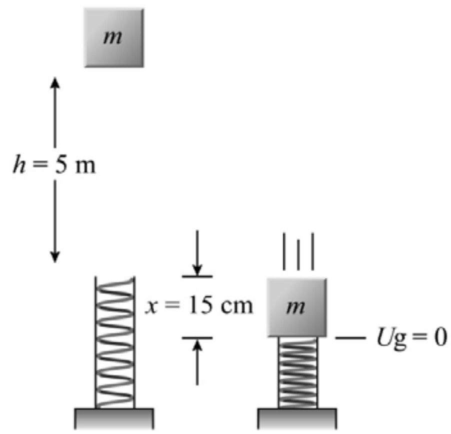
$$x = \frac{mg(\sin\theta + \mu_s\cos\theta)}{k}$$

Substitute for x in the expression for U:

$$U = \tfrac{1}{2}k\left[\frac{mg(\sin\theta + \mu_s\cos\theta)}{k}\right]^2 = \boxed{\frac{[mg(\sin\theta + \mu_s\cos\theta)]^2}{2k}}$$

26 ••

Picture the Problem The mechanical energy of the system, consisting of the block, the spring, and the earth, is initially entirely gravitational potential energy. Let $U_g = 0$ where the spring is compressed 15 cm. Then the mechanical energy when the compression of the spring is 15 cm will be partially kinetic and partially stored in the spring. We can use conservation of energy to relate the initial potential energy of the system to the energy stored in the spring and the kinetic energy of block when it has compressed the spring 15 cm.



Apply conservation of energy to the system:

$$\Delta U + \Delta K = 0$$

or

$$U_{g,f} - U_{g,i} + U_{s,f} - U_{s,i} + K_f - K_i = 0$$

Because $U_{g,f} = U_{s,I} = K_i = 0$:

$$-U_{g,i} + U_{s,f} + K_f = 0$$

Substitute to obtain:

$$-mg(h + x) + \tfrac{1}{2}kx^2 + \tfrac{1}{2}mv^2 = 0$$

Solve for v:

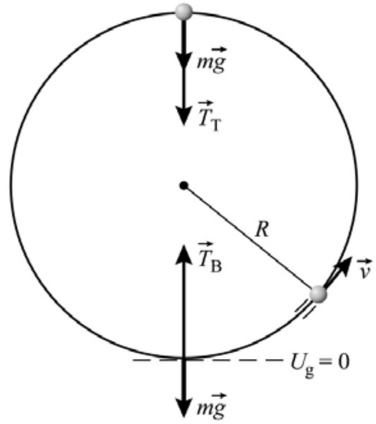
$$v = \sqrt{2g(h + x) - \frac{kx^2}{m}}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{2(9.81\,\text{m/s}^2)(5\,\text{m} + 0.15\,\text{m}) - \frac{(3955\,\text{N/m})(0.15\,\text{m})^2}{2.4\,\text{kg}}} = \boxed{8.00\,\text{m/s}}$$

***27 ••**

Picture the Problem The diagram represents the ball traveling in a circular path with constant energy. U_g has been chosen to be zero at the lowest point on the circle and the superimposed free-body diagrams show the forces acting on the ball at the top and bottom of the circular path. We'll apply Newton's 2nd law to the ball at the top and bottom of its path to obtain a relationship between T_T and T_B and the conservation of mechanical energy to relate the speeds of the ball at these two locations.



Apply $\sum F_{radial} = ma_{radial}$ to the ball at the bottom of the circle and solve for T_B:

$$T_B - mg = m\frac{v_B^2}{R}$$

and

$$T_B = mg + m\frac{v_B^2}{R} \quad (1)$$

Apply $\sum F_{radial} = ma_{radial}$ to the ball at the top of the circle and solve for T_T:

$$T_T + mg = m\frac{v_T^2}{R}$$

and

$$T_T = -mg + m\frac{v_T^2}{R} \quad (2)$$

Subtract equation (2) from equation (1) to obtain:

$$T_B - T_T = mg + m\frac{v_B^2}{R} - \left(-mg + m\frac{v_T^2}{R}\right) = m\frac{v_B^2}{R} - m\frac{v_T^2}{R} + 2mg \quad (3)$$

Using conservation of energy, relate the mechanical energy of the ball at the bottom of its path to its mechanical energy at the top of the circle and solve for $m\frac{v_B^2}{R} - m\frac{v_T^2}{R}$:

$$\tfrac{1}{2}mv_B^2 = \tfrac{1}{2}mv_T^2 + mg(2R)$$

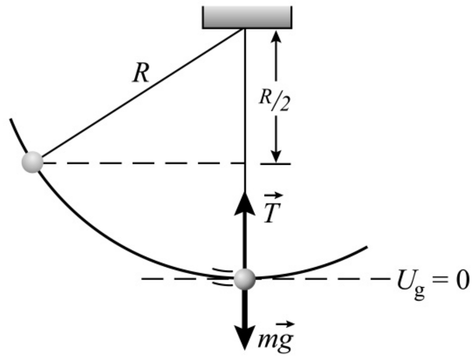
$$m\frac{v_B^2}{R} - m\frac{v_T^2}{R} = 4mg$$

Substitute in equation (3) to obtain:

$$T_B - T_T = \boxed{6mg}$$

28 ••

Picture the Problem Let $U_g = 0$ at the lowest point in the girl's swing. Then we can equate her initial potential energy to her kinetic energy as she passes through the low point on her swing to relate her speed v to R. The FBD show the forces acting on the girl at the low point of her swing. Applying Newton's 2nd law to her will allow us to establish the relationship between the tension T and her speed.



Apply $\sum F_{\text{radial}} = ma_{\text{radial}}$ to the girl at her lowest point and solve for T:

$$T - mg = m\frac{v^2}{R}$$

and

$$T = mg + m\frac{v^2}{R}$$

Equate the girl's initial potential energy to her final kinetic energy and solve for $\frac{v^2}{R}$:

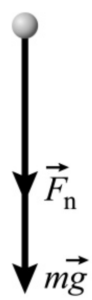
$$mg\frac{R}{2} = \tfrac{1}{2}mv^2 \Rightarrow \frac{v^2}{R} = g$$

Substitute for v^2/R^2 and simplify to obtain:

$$T = mg + mg = \boxed{2mg}$$

29 ••

Picture the Problem The free-body diagram shows the forces acting on the car when it is upside down at the top of the loop. Choose $U_g = 0$ at the bottom of the loop. We can express F_n in terms of v and R by apply Newton's 2nd law to the car and then obtain a second expression in these same variables by applying the conservation of mechanical energy. The simultaneous solution of these equations will yield an expression for F_n in terms of known quantities.



Apply $\sum F_{\text{radial}} = ma_{\text{radial}}$ to the car at the top of the circle and solve for F_n:

$$F_n + mg = m\frac{v^2}{R}$$

and

$$F_n = m\frac{v^2}{R} - mg \qquad (1)$$

Using conservation of energy, relate the energy of the car at the beginning of its motion to its energy when it is at the top of the loop:

$$mgH = \tfrac{1}{2}mv^2 + mg(2R)$$

Solve for $m\dfrac{v^2}{R}$:

$$m\frac{v^2}{R} = 2mg\left(\frac{H}{R} - 2\right) \qquad (2)$$

Substitute equation (2) in equation (1) to obtain:

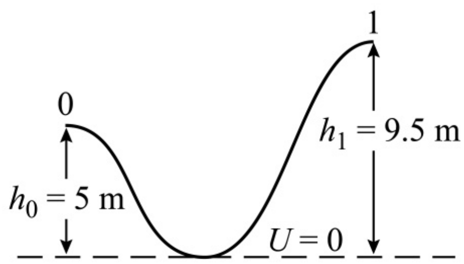
$$F_n = 2mg\left(\frac{H}{R} - 2\right) - mg = mg\left(\frac{2H}{R} - 5\right)$$

Substitute numerical values and evaluate F_n:

$$F_n = (1500\,\text{kg})(9.81\,\text{m/s}^2)\left[\frac{2(23\,\text{m})}{7.5\,\text{m}} - 5\right] = 1.67\times10^4\ \text{N} \Rightarrow \boxed{(c)\ \text{is correct.}}$$

30 •

Picture the Problem Let the system include the roller coaster, the track, and the earth and denote the starting position with the numeral 0 and the top of the second hill with the numeral 1. We can use the work-energy theorem to relate the energies of the coaster at its initial and final positions.



(*a*) Use conservation of energy to relate the work done by external forces to the change in the energy of the system:

$$W_{ext} = \Delta E_{sys} = \Delta K + \Delta U$$

Because the track is frictionless, $W_{ext} = 0$:

$$\Delta K + \Delta U = 0$$

and

$$K_1 - K_0 + U_1 - U_0 = 0$$

Substitute to obtain:

$$\tfrac{1}{2}mv_1^2 - \tfrac{1}{2}mv_0^2 + mgh_1 - mgh_0 = 0$$

Solve for v_0:

$$v_0 = \sqrt{v_1^2 + 2g(h_1 - h_0)}$$

If the coaster just makes it to the top of the second hill, $v_1 = 0$ and:

$$v_0 = \sqrt{2g(h_1 - h_0)}$$

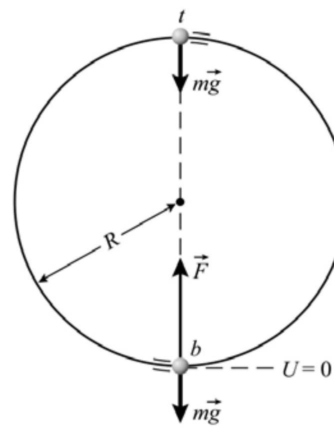
Substitute numerical values and evaluate v_0:

$$v_0 = \sqrt{2(9.81\,\text{m/s}^2)(9.5\,\text{m} - 5\,\text{m})} = \boxed{9.40\,\text{m/s}}$$

(*b*) No. Note that the required speed depends only on the difference in the heights of the two hills.

31 ••

Picture the Problem Let the radius of the loop be R and the mass of one of the riders be m. At the top of the loop, the centripetal force on her is her weight (the force of gravity). The two forces acting on her at the bottom of the loop are the normal force exerted by the seat of the car, pushing up, and the force of gravity, pulling down. We can apply Newton's 2nd law to her at both the top and bottom of the loop to relate the speeds at those locations to m and R and, at b, to F, and then use conservation of energy to relate v_t and v_b.



Apply $\sum F_{\text{radial}} = ma_{\text{radial}}$ to the rider at the bottom of the circular arc:

$$F - mg = m\frac{v_{\text{b}}^2}{R}$$

Solve for F to obtain:

$$F = mg + m\frac{v_{\text{b}}^2}{R} \qquad (1)$$

Apply $\sum F_{\text{radial}} = ma_{\text{radial}}$ to the rider at the top of the circular arc:

$$mg = m\frac{v_{\text{t}}^2}{R}$$

Solve for v_{t}^2:

$$v_{\text{t}}^2 = gR$$

Use conservation of energy to relate the energies of the rider at the top and bottom of the arc:

$$K_{\text{b}} - K_{\text{t}} + U_{\text{b}} - U_{\text{t}} = 0$$

or, because $U_{\text{b}} = 0$,

$$K_{\text{b}} - K_{\text{t}} - U_{\text{t}} = 0$$

Substitute to obtain:

$$\tfrac{1}{2}mv_{\text{b}}^2 - \tfrac{1}{2}mv_{\text{t}}^2 - 2mgR = 0$$

Solve for v_{b}^2:

$$v_b^2 = 5gR$$

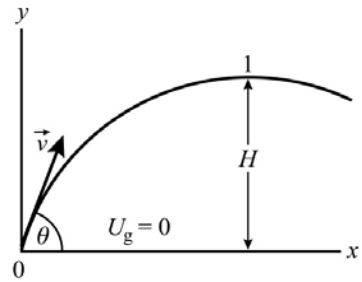
Substitute in equation (1) to obtain:

$$F = mg + m\frac{5gR}{R} = \boxed{6mg}$$

i.e., the rider will feel six times heavier than her normal weight.

***32 ••**

Picture the Problem Let the system consist of the stone and the earth and ignore the influence of air resistance. Then $W_{ext} = 0$. Choose $U_g = 0$ as shown in the figure. Apply the law of the conservation of mechanical energy to describe the energy transformations as the stone rises to the highest point of its trajectory.



Apply conservation of energy:

$$W_{ext} = \Delta K + \Delta U = 0$$

and

$$K_1 - K_0 + U_1 - U_0 = 0$$

Because $U_0 = 0$:

$$K_1 - K_0 + U_1 = 0$$

Substitute to obtain:

$$\tfrac{1}{2}mv_x^2 - \tfrac{1}{2}mv^2 + mgH = 0$$

In the absence of air resistance, the horizontal component of $\vec{v}$ is constant and equal to $v_x = v\cos\theta$. Hence:

$$\tfrac{1}{2}m(v\cos\theta)^2 - \tfrac{1}{2}mv^2 + mgH = 0$$

Solve for v:

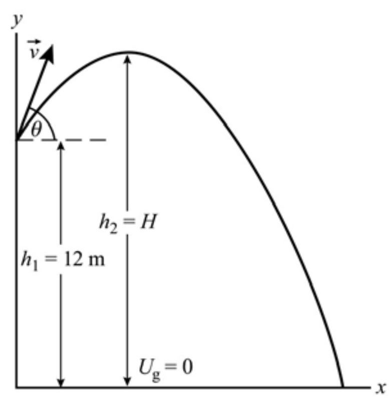
$$v = \sqrt{\frac{2gH}{1-\cos^2\theta}}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{\frac{2(9.81\,\text{m/s}^2)(24\,\text{m})}{1-\cos^2 53°}} = \boxed{27.2\,\text{m/s}}$$

33 ••

Picture the Problem Let the system consist of the ball and the earth. Then $W_{ext} = 0$. The figure shows the ball being thrown from the roof of a building. Choose $U_g = 0$ at ground level. We can use the conservation of mechanical energy to determine the maximum height of the ball and its speed at impact with the ground. We can use the definition of the work done by gravity to calculate how much work was done by gravity as the ball rose to its maximum height.



(*a*) Apply conservation of energy:

$$W_{ext} = \Delta K + \Delta U = 0$$

or

$$K_2 - K_1 + U_2 - U_1 = 0$$

Substitute for the energies to obtain:

$$\tfrac{1}{2}mv_2^2 - \tfrac{1}{2}mv_1^2 + mgh_2 - mgh_1 = 0$$

Note that, at point 2, the ball is moving horizontally and:

$$v_2 = v_1 \cos\theta$$

Substitute for v_2 and h_2:

$$\tfrac{1}{2}m(v_1 \cos\theta)^2 - \tfrac{1}{2}mv_1^2 + mgH - mgh_1 = 0$$

Solve for H:

$$H = h_1 - \frac{v^2}{2g}\left(\cos^2\theta - 1\right)$$

Substitute numerical values and evaluate H:

$$H = 12\,\text{m} - \frac{(30\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)}\left(\cos^2 40° - 1\right) = \boxed{31.0\,\text{m}}$$

(*b*) Using its definition, express the work done by gravity:

$$W_g = -\Delta U = -\left(U_H - U_{h_i}\right) = -\left(mgH - mgh_i\right) = -mg\left(H - h_i\right)$$

Substitute numerical values and evaluate W_g:

$$W_g = -(0.17\,\text{kg})(9.81\,\text{m/s}^2)(31\,\text{m} - 12\,\text{m}) = \boxed{-31.7\,\text{J}}$$

(*c*) Relate the initial mechanical energy of the ball to its just-before-impact energy:

$$\tfrac{1}{2}mv_i^2 + mgh_i = \tfrac{1}{2}mv_f^2$$

Solve for v_f:

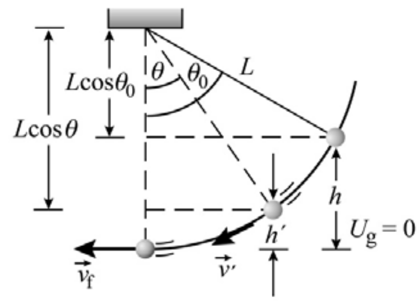
$$v_f = \sqrt{v_i^2 + 2gh_i}$$

Substitute numerical values and evaluate v_f

$$v_f = \sqrt{(30\,\text{m/s})^2 + 2(9.81\,\text{m/s}^2)(12\,\text{m})} = \boxed{33.7\,\text{m/s}}$$

34 ••

Picture the Problem The figure shows the pendulum bob in its release position and in the two positions in which it is in motion with the given speeds. Choose $U_g = 0$ at the low point of the swing. We can apply the conservation of mechanical energy to relate the two angles of interest to the speeds of the bob at the intermediate and low points of its trajectory.



(*a*) Apply conservation of energy:

$$W_{ext} = \Delta K + \Delta U = 0$$

or

$$K_f - K_i + U_f - U_i = 0$$

where U_f and K_i equal zero.

$$\therefore K_f - U_i = 0$$

Express U_i:

$$U_i = mgh = mgL(1-\cos\theta_0)$$

Substitute for K_f and U_i:

$$\tfrac{1}{2}mv_f^2 - mgL(1-\cos\theta_0) = 0$$

Solve for θ_0:

$$\theta_0 = \cos^{-1}\left(1-\frac{v^2}{2gL}\right)$$

Substitute numerical values and evaluate θ_0:

$$\theta_0 = \cos^{-1}\left[1-\frac{(2.8\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)(0.8\,\text{m})}\right]$$

$$= \boxed{60.0°}$$

(*b*) Letting primed quantities describe the indicated location, use the law of the conservation of mechanical energy to relate the speed of the bob at this point to θ:

$$K_f' - K_i + U_f' - U_i = 0$$

where $K_i = 0$.

$$\therefore K_f' + U_f' - U_i = 0$$

Express U_f':

$$U_f' = mgh' = mgL(1-\cos\theta)$$

Substitute for K_f', U_f' and U_i:

$$\tfrac{1}{2}m(v_f')^2 + mgL(1-\cos\theta) - mgL(1-\cos\theta_0) = 0$$

Solve for θ:

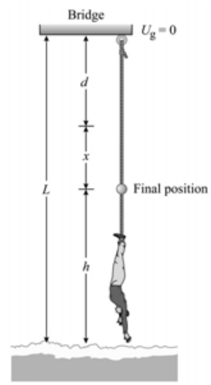
$$\theta = \cos^{-1}\left[\frac{(v_f')^2}{2gL} + \cos\theta_0\right]$$

Substitute numerical values and evaluate θ:

$$\theta = \cos^{-1}\left[\frac{(1.4\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)(0.8\,\text{m})} + \cos 60°\right] = \boxed{51.3°}$$

***35** ••

Picture the Problem Choose $U_g = 0$ at the bridge, and let the system be the earth, the jumper and the bungee cord. Then $W_{ext} = 0$. Use the conservation of mechanical energy to relate to relate her initial and final gravitational potential energies to the energy stored in the stretched bungee, U_s cord. In part (*b*), we'll use a similar strategy but include a kinetic energy term because we are interested in finding her maximum speed.



(*a*) Express her final height *h* above the water in terms of *L*, *d* and the distance *x* the bungee cord has stretched:

$$h = L - d - x \qquad (1)$$

Use the conservation of mechanical energy to relate her gravitational potential energy as she just touches the water to the energy stored in the stretched bungee cord:

$$W_{ext} = \Delta K + \Delta U = 0$$

Because $\Delta K = 0$ and $\Delta U = \Delta U_g + \Delta U_s$,

$$-mgL + \tfrac{1}{2}kx^2 = 0,$$

where x is the maximum distance the bungee cord has stretched.

Solve for *k*:

$$k = \frac{2mgL}{x^2}$$

Find the maximum distance the bungee cord stretches:

$x = 310\text{ m} - 50\text{ m} = 260\text{ m}.$

Evaluate *k*:

$$k = \frac{2(60\,\text{kg})(9.81\,\text{m/s}^2)(310\,\text{m})}{(260\,\text{m})^2} = 5.40\,\text{N/m}$$

Express the relationship between the forces acting on her when she has finally come to rest and solve for x:

$$F_{\text{net}} = kx - mg = 0$$

and

$$x = \frac{mg}{k}$$

Evaluate x:

$$x = \frac{(60\,\text{kg})(9.81\,\text{m/s}^2)}{5.40\,\text{N/m}} = 109\,\text{m}$$

Substitute in equation (1) and evaluate h:

$$h = 310\,\text{m} - 50\,\text{m} - 109\,\text{m} = \boxed{151\,\text{m}}$$

(b) Using conservation of energy, express her total energy E:

$$E = K + U_{\text{g}} + U_{\text{s}} = E_{\text{i}} = 0$$

Because v is a maximum when K is a maximum, solve for K::

$$K = -U_{\text{g}} - U_{\text{s}} = mg(d + x) - \tfrac{1}{2}kx^2 \qquad (1)$$

Use the condition for an extreme value to obtain:

$$\frac{dK}{dx} = mg - kx = 0 \text{ for extreme values}$$

Solve for and evaluate x:

$$x = \frac{mg}{k} = \frac{(60\,\text{kg})(9.81\,\text{m/s}^2)}{5.40\,\text{N/m}} = 109\,\text{m}$$

From equation (1) we have:

$$\tfrac{1}{2}mv^2 = mg(d + x) - \tfrac{1}{2}kx^2$$

Solve for v to obtain:

$$v = \sqrt{2g(d + x) - \frac{kx^2}{m}}$$

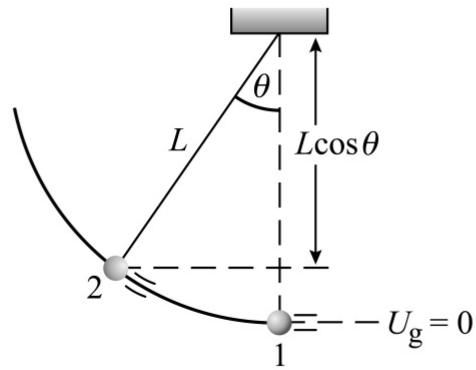
Substitute numerical values and evaluate v for x = 109 m:

$$v = \sqrt{2(9.81\,\text{m/s}^2)(50\,\text{m} + 109\,\text{m}) - \frac{(5.4\,\text{N/m})(109\,\text{m})^2}{60\,\text{kg}}} = \boxed{45.3\,\text{m/s}}$$

Because $\dfrac{d^2K}{dx^2} = -k < 0$, x = 109 m corresponds to $K_{\max}$ and so v is a maximum.

36 ••

Picture the Problem Let the system be the earth and pendulum bob. Then $W_{ext} = 0$. Choose $U_g = 0$ at the low point of the bob's swing and apply the law of the conservation of mechanical energy to its motion. When the bob reaches the 30° position its energy will be partially kinetic and partially potential. When it reaches its maximum height, its energy will be entirely potential. Applying Newton's 2nd law will allow us to express the tension in the string as a function of the bob's speed and its angular position.



(*a*) Apply conservation of energy to relate the energies of the bob at points 1 and 2:

$$W_{ext} = \Delta K + \Delta U = 0$$

or

$$K_2 - K_1 + U_2 - U_1 = 0$$

Because $U_1 = 0$:

$$\tfrac{1}{2}mv_2^2 - \tfrac{1}{2}mv_1^2 + U_2 = 0$$

Express U_2:

$$U_2 = mgL(1 - \cos\theta)$$

Substitute for U_2 to obtain:

$$\tfrac{1}{2}mv_2^2 - \tfrac{1}{2}mv_1^2 + mgL(1 - \cos\theta) = 0$$

Solve for v_2:

$$v_2 = \sqrt{v_1^2 - 2gL(1 - \cos\theta)}$$

Substitute numerical values and evaluate v_2:

$$v_2 = \sqrt{(4.5\,\text{m/s})^2 - 2(9.81\,\text{m/s}^2)(3\,\text{m})(1 - \cos 30°)} = \boxed{3.52\,\text{m/s}}$$

(*b*) From (*a*) we have:

$$U_2 = mgL(1 - \cos\theta)$$

Substitute numerical values and evaluate U_2:

$$U_2 = (2\,\text{kg})(9.81\,\text{m/s}^2)(3\,\text{m})(1 - \cos 30°) = \boxed{7.89\,\text{J}}$$

(*c*) Apply $\sum F_{radial} = ma_{radial}$ to the bob to obtain:

$$T - mg\cos\theta = m\frac{v_2^2}{L}$$

Solve for T:

$$T = m\left(g\cos\theta + \frac{v_2^2}{L}\right)$$

Substitute numerical values and evaluate T:

$$T = (2\,\text{kg})\left[(9.81\,\text{m/s}^2)\cos 30° + \frac{(3.52\,\text{m/s})^2}{3\,\text{m}}\right] = \boxed{25.3\,\text{N}}$$

(*d*) When the bob reaches its greatest height:

$$U = U_{max} = mgL(1 - \cos\theta_{max})$$

and

$$K_1 + U_{max} = 0$$

Substitute for K_1 and U_{max}

$$-\tfrac{1}{2}mv_1^2 + mgL(1 - \cos\theta_{max}) = 0$$

Solve for θ_{max}:

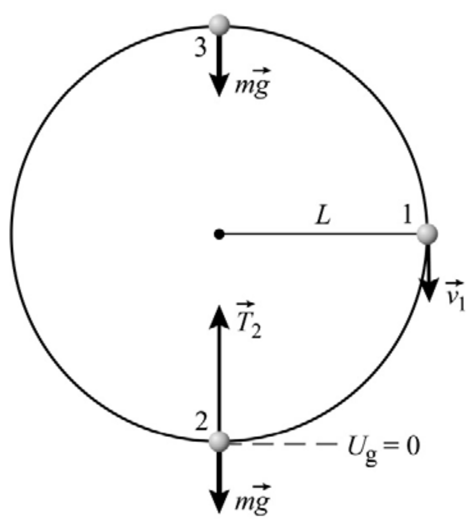
$$\theta_{max} = \cos^{-1}\left(1 - \frac{v_1^2}{2gL}\right)$$

Substitute numerical values and evaluate θ_{max}:

$$\theta_{max} = \cos^{-1}\left[1 - \frac{(4.5\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)(3\,\text{m})}\right] = \boxed{49.0°}$$

37 ••

Picture the Problem Let the system consist of the earth and pendulum bob. Then $W_{ext} = 0$. Choose $U_g = 0$ at the bottom of the circle and let points 1, 2 and 3 represent the bob's initial point, lowest point and highest point, respectively. The bob will gain speed and kinetic energy until it reaches point 2 and slow down until it reaches point 3; so it has its maximum kinetic energy when it is at point 2. We can use Newton's 2nd law at points 2 and 3 in conjunction with the law of the conservation of mechanical energy to find the maximum kinetic energy of the bob and the tension in the string when the bob has its maximum kinetic energy.



(*a*) Apply $\sum F_{radial} = ma_{radial}$ to the bob at the top of the circle and solve for v_3^2:

$$mg = m\frac{v_3^2}{L}$$

and

$$v_3^2 = gL$$

Use conservation of energy to express the relationship between K_2, K_3 and U_3 and solve for K_2:

$K_3 - K_2 + U_3 - U_2 = 0$ where $U_2 = 0$

Therefore,

$$K_2 = K_{max} = K_3 + U_3 = \tfrac{1}{2}mv_3^2 + mg(2L)$$

Substitute for v_3^2 and simplify to obtain:

$$K_{max} = \tfrac{1}{2}m(gL) + 2mgL = \boxed{\tfrac{5}{2}mgL}$$

(*b*) Apply $\sum F_{radial} = ma_{radial}$ to the bob at the bottom of the circle and solve for T_2:

$$F_{net} = T_2 - mg = m\frac{v_2^2}{L}$$

and

$$T_2 = mg + m\frac{v_2^2}{L} \qquad (1)$$

Use conservation of energy to relate the energies of the bob at points 2 and 3 and solve for K_2:

$K_3 - K_2 + U_3 - U_2 = 0$ where $U_2 = 0$

$$K_2 = K_3 + U_3 = \tfrac{1}{2}mv_3^2 + mg(2L)$$

Substitute for v_3^2 and K_2 and solve for v_2^2:

$$\tfrac{1}{2}mv_2^2 = \tfrac{1}{2}m(gL) + mg(2L)$$

and

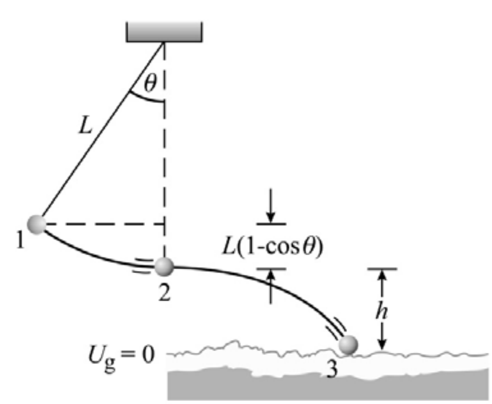
$$v_2^2 = 5gL$$

Substitute in equation (1) to obtain:

$$T_2 = \boxed{6mg}$$

38 ••

Picture the Problem Let the system consist of the earth and child. Then $W_{ext} = 0$. In the figure, the child's initial position is designated with the numeral 1; the point at which the child releases the rope and begins to fall with a 2, and its point of impact with the water is identified with a 3. Choose $U_g = 0$ at the water level. While one could use the law of the conservation of energy between points 1 and 2 and then between points 2 and 3, it is more direct to consider the energy transformations between points 1 and 3. Given our choice of the zero of gravitational potential energy, the initial potential energy at point 1 is transformed into kinetic energy at point 3.



Apply conservation of energy to the energy transformations between points 1 and 3:

$$W_{ext} = \Delta K + \Delta U = 0$$
$$K_3 - K_1 + U_3 - U_1 = 0$$
where U_3 and K_1 are zero.

Substitute for K_3 and U_1;

$$\tfrac{1}{2}mv_3^2 - mg[h + L(1-\cos\theta)] = 0$$

Solve for v_3:

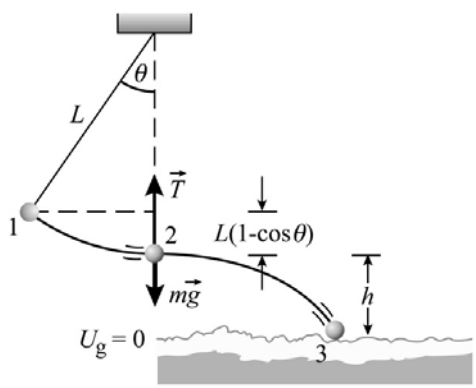
$$v_3 = \sqrt{2g[h + L(1-\cos\theta)]}$$

Substitute numerical values and evaluate v_3:

$$v_3 = \sqrt{2(9.81\,\text{m/s}^2)[3.2\,\text{m} + (10.6\,\text{m})(1-\cos 23°)]} = \boxed{8.91\,\text{m/s}}$$

***39 ••**

Picture the Problem Let the system consist of you and the earth. Then there are no external forces to do work on the system and W_{ext} = 0. In the figure, your initial position is designated with the numeral 1, the point at which you release the rope and begin to fall with a 2, and your point of impact with the water is identified with a 3. Choose U_g = 0 at the water level. We can apply Newton's 2nd law to the forces acting on you at point 2 and apply conservation of energy between points 1 and 2 to determine the maximum angle at which you can begin your swing and then between points 1 and 3 to determine the speed with which you will hit the water.



(*a*) Use conservation of energy to relate your speed at point 2 to your potential energy there and at point 1:

$$W_{ext} = \Delta K + \Delta U = 0$$
or
$$K_2 - K_1 + U_2 - U_1 = 0$$

Because K_1 = 0:

$$\tfrac{1}{2}mv_2^2 + mgh - [mgL(1-\cos\theta) + mgh] = 0$$

Solve this equation for θ:

$$\theta = \cos^{-1}\left[1 - \frac{v_2^2}{2gL}\right] \qquad (1)$$

Apply $\sum F_{radial} = ma_{radial}$ to

$$T - mg = m\frac{v_2^2}{L}$$

yourself at point 2 and solve for T:

and

$$T = mg + m\frac{v_2^2}{L}$$

Because you've estimated that the rope might break if the tension in it exceeds your weight by 80 N, it must be that:

$$m\frac{v_2^2}{L} = 80\,\text{N}$$

or

$$v_2^2 = \frac{(80\text{ N})L}{m}$$

Let's assume your weight is 650 N. Then your mass is 66.3 kg and:

$$v_2^2 = \frac{(80\text{ N})(4.6\,\text{m})}{66.3\text{kg}} = 5.55\,\text{m}^2/\text{s}^2$$

Substitute numerical values in equation (1) to obtain:

$$\theta = \cos^{-1}\left[1 - \frac{5.55\,\text{m}^2/\text{s}^2}{2(9.81\,\text{m/s}^2)(4.6\,\text{m})}\right] = \boxed{20.2°}$$

(*b*) Apply conservation of energy to the energy transformations between points 1 and 3:

$$W_{\text{ext}} = \Delta K + \Delta U = 0$$

$K_3 - K_1 + U_3 - U_1 = 0$ where U_3 and K_1 are zero

Substitute for K_3 and U_1 to obtain:

$$\tfrac{1}{2}mv_3^2 - mg[h + L(1 - \cos\theta)] = 0$$

Solve for v_3:

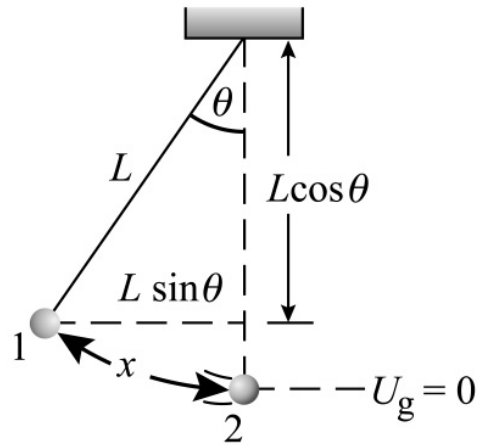
$$v_3 = \sqrt{2g[h + L(1 - \cos\theta)]}$$

Substitute numerical values and evaluate v_3:

$$v_3 = \sqrt{2(9.81\,\text{m/s}^2)[1.8\,\text{m} + (4.6\,\text{m})(1 - \cos 20.2°)]} = \boxed{6.39\,\text{m/s}}$$

40 ••

Picture the Problem Choose $U_g = 0$ at point 2, the lowest point of the bob's trajectory and let the system consist of the bob and the earth. Given this choice, there are no external forces doing work on the system. Because $\theta << 1$, we can use the trigonometric series for the sine and cosine functions to approximate these functions. The bob's initial energy is partially gravitational potential and partially potential energy stored in the stretched spring. As the bob swings down to point 2 this energy is transformed into kinetic energy. By equating these energies, we can derive an expression for the speed of the bob at point 2.



Apply conservation of energy to the system as the pendulum bob swings from point 1 to point 2:

$$\tfrac{1}{2}mv_2^2 = \tfrac{1}{2}kx^2 + mgL(1-\cos\theta)$$

Note, from the figure, that $x \approx L\sin\theta$ when $\theta << 1$:

$$\tfrac{1}{2}mv_2^2 = \tfrac{1}{2}k(L\sin\theta)^2 + mgL(1-\cos\theta)$$

Also, when $\theta << 1$:

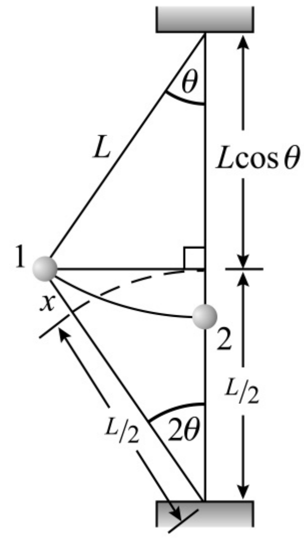
$$\sin\theta \approx \theta \text{ and } \cos\theta \approx 1 - \tfrac{1}{2}\theta^2$$

Substitute, simplify and solve for v_2:

$$v_2 = \boxed{L\theta\sqrt{\frac{k}{m} + \frac{g}{L}}}$$

41 •••

Picture the Problem Choose $U_g = 0$ at point 2, the lowest point of the bob's trajectory and let the system consist of the earth, ceiling, spring, and pendulum bob. Given this choice, there are no external forces doing work to change the energy of the system. The bob's initial energy is partially gravitational potential and partially potential energy stored in the stretched spring. As the bob swings down to point 2 this energy is transformed into kinetic energy. By equating these energies, we can derive an expression for the speed of the bob at point 2.



Apply conservation of energy to the system as the pendulum bob swings from point 1 to point 2:

$$\tfrac{1}{2}mv_2^2 = \tfrac{1}{2}kx^2 + mgL(1-\cos\theta) \quad (1)$$

Apply the Pythagorean theorem to the lower triangle in the diagram to obtain:

$$\left(x+\tfrac{1}{2}L\right)^2 = L^2\left[\sin^2\theta + \left(\tfrac{3}{2}\cos\theta\right)^2\right] = L^2\left[\sin^2\theta + \tfrac{9}{4} - 3\cos\theta + \cos^2\theta\right] = L^2\left(\tfrac{13}{4} - 3\cos\theta\right)$$

Take the square root of both sides of the equation to obtain:

$$x + \tfrac{1}{2}L = L\sqrt{\left(\tfrac{13}{4} - 3\cos\theta\right)}$$

Solve for x:

$$x = L\left[\sqrt{\left(\tfrac{13}{4} - 3\cos\theta\right)} - \tfrac{1}{2}\right]$$

Substitute for x in equation (1):

$$\tfrac{1}{2}mv_2^2 = \tfrac{1}{2}kL^2\left[\sqrt{\left(\tfrac{13}{4} - 3\cos\theta\right)} - \tfrac{1}{2}\right]^2 + mgL(1-\cos\theta)$$

Solve for v_2^2 to obtain:

$$v_2^2 = 2gL(1-\cos\theta) + \frac{k}{m}L^2\left[\sqrt{\tfrac{13}{4} - 3\cos\theta} - \tfrac{1}{2}\right]^2$$

$$= L^2\left[2\frac{g}{L}(1-\cos\theta) + \frac{k}{m}\left(\sqrt{\tfrac{13}{4} - 3\cos\theta} - \tfrac{1}{2}\right)^2\right]$$

Finally, solve for v_2:

$$v_2 = \boxed{L\sqrt{2\frac{g}{L}(1-\cos\theta)+\frac{k}{m}\left(\sqrt{\tfrac{13}{4}-3\cos\theta}-\tfrac{1}{2}\right)^2}}$$

The Conservation of Energy

42 •

Picture the Problem The energy of the eruption is initially in the form of the kinetic energy of the material it thrusts into the air. This energy is then transformed into gravitational potential energy as the material rises.

(*a*) Express the energy of the eruption in terms of the height Δh to which the debris rises:

$$E = mg\Delta h$$

Relate the density of the material to its mass and volume:

$$\rho = \frac{m}{V}$$

Substitute for m to obtain:

$$E = \rho Vg\Delta h$$

Substitute numerical values and evaluate E:

$$E = (1600\,\text{kg/m}^3)(4\,\text{km}^3)(9.81\,\text{m/s}^2)(500\,\text{m}) = \boxed{3.14\times10^{16}\,\text{J}}$$

(*b*) Convert 3.13×10^{16} J to megatons of TNT:

$$3.14\times10^{16}\,\text{J} = 3.14\times10^{16}\,\text{J}\times\frac{1\,\text{Mton TNT}}{4.2\times10^{15}\,\text{J}} = \boxed{7.48\,\text{Mton TNT}}$$

43 ••

Picture the Problem The work done by the student equals the change in his/her gravitational potential energy and is done as a result of the transformation of metabolic energy in the climber's muscles.

(*a*) The increase in gravitational potential energy is:

$$\Delta U = mg\Delta h = (80\,\text{kg})(9.81\,\text{m/s}^2)(120\,\text{m}) = \boxed{94.2\,\text{kJ}}$$

(*b*) The energy required to do this work comes from chemical energy stored in the body.

(*c*) Relate the chemical energy expended by the student to the change in his/her potential energy and solve for *E*:

$$0.2E = \Delta U$$

and

$$E = 5\Delta U = 5(94.2\text{ kJ}) = \boxed{471\text{ kJ}}$$

Kinetic Friction

44 •

Picture the Problem Let the car and the earth be the system. As the car skids to a stop on a horizontal road, its kinetic energy is transformed into internal (i.e., thermal) energy. Knowing that energy is transformed into heat by friction, we can use the definition of the coefficient of kinetic friction to calculate its value.

(*a*) The energy dissipated by friction is given by:

$$f\Delta s = \Delta E_{\text{therm}}$$

Apply the work-energy theorem for problems with kinetic friction:

$$W_{\text{ext}} = \Delta E_{\text{mech}} + \Delta E_{\text{therm}} = \Delta E_{\text{mech}} + f\Delta s$$

or, because $\Delta E_{\text{mech}} = \Delta K = -K_{\text{i}}$ and $W_{\text{ext}} = 0$,

$$0 = -\tfrac{1}{2}mv_{\text{i}}^2 + f\Delta s$$

Solve for $f\Delta s$ to obtain:

$$f\Delta s = \tfrac{1}{2}mv_{\text{i}}^2$$

Substitute numerical values and evaluate $f\Delta s$:

$$f\Delta s = \tfrac{1}{2}(2000\text{ kg})(25\text{ m/s})^2 = \boxed{625\text{ kJ}}$$

(*b*) Relate the kinetic friction force to the coefficient of kinetic friction and the weight of the car and solve for the coefficient of kinetic friction:

$$f_{\text{k}} = \mu_{\text{k}}mg \Rightarrow \mu_{\text{k}} = \frac{f_{\text{k}}}{mg}$$

Express the relationship between the energy dissipated by friction and the kinetic friction force and solve f_{k}:

$$\Delta E_{\text{therm}} = f_{\text{k}}\Delta s \Rightarrow f_{\text{k}} = \frac{\Delta E_{\text{therm}}}{\Delta s}$$

Substitute to obtain:

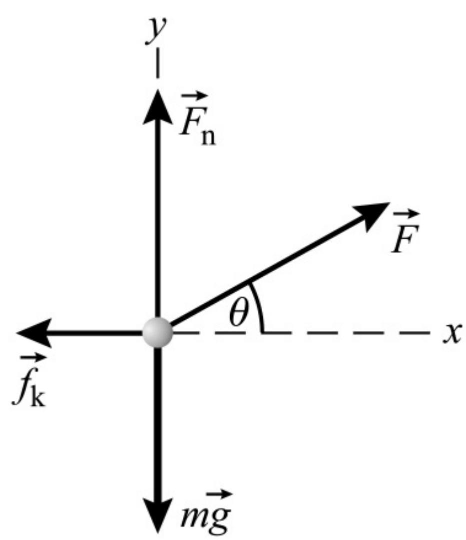
$$\mu_{\text{k}} = \frac{\Delta E_{\text{therm}}}{mg\Delta s}$$

Substitute numerical values and evaluate μ_k:

$$\mu_k = \frac{625\,\text{kJ}}{(2000\,\text{kg})(9.81\,\text{m/s}^2)(60\,\text{m})} = \boxed{0.531}$$

45 •

Picture the Problem Let the system be the sled and the earth. Then the 40-N force is external to the system. The free-body diagram shows the forces acting on the sled as it is pulled along a horizontal road. The work done by the applied force can be found using the definition of work. To find the energy dissipated by friction, we'll use Newton's 2nd law to determine f_k and then use it in the definition of work. The change in the kinetic energy of the sled is equal to the net work done on it. Finally, knowing the kinetic energy of the sled after it has traveled 3 m will allow us to solve for its speed at that location.



(*a*) Use the definition of work to calculate the work done by the applied force:

$$W_{ext} \equiv \vec{F}\cdot\vec{s} = Fs\cos\theta = (40\,\text{N})(3\,\text{m})\cos 30° = \boxed{104\,\text{J}}$$

(*b*) Express the energy dissipated by friction as the sled is dragged along the surface:

$$\Delta E_{therm} = f\Delta x = \mu_k F_n \Delta x$$

Apply $\sum F_y = ma_y$ to the sled and solve for F_n:

$$F_n + F\sin\theta - mg = 0$$

and

$$F_n = mg - F\sin\theta$$

Substitute to obtain:

$$\Delta E_{therm} = \mu_k \Delta x(mg - F\sin\theta)$$

Substitute numerical values and evaluate ΔE_{therm}:

$$\Delta E_{therm} = (0.4)(3\,\text{m})[(8\,\text{kg})(9.81\,\text{m/s}^2) - (40\,\text{N})\sin 30°] = \boxed{70.2\,\text{J}}$$

(*c*) Apply the work-energy theorem

$$W_{ext} = \Delta E_{mech} + \Delta E_{therm} = \Delta E_{mech} + f\Delta s$$

for problems with kinetic friction:

or, because $\Delta E_{\text{mech}} = \Delta K + \Delta U$ and $\Delta U = 0$,
$W_{\text{ext}} = \Delta K + \Delta E_{\text{therm}}$

Solve for and evaluate ΔK to obtain:

$$\Delta K = W_{\text{ext}} - \Delta E_{\text{therm}} = 104\,\text{J} - 70.2\,\text{J} = \boxed{33.8\,\text{J}}$$

(*d*) Because $K_i = 0$:

$$K_f = \Delta K = \tfrac{1}{2}mv_f^2$$

Solve for v_f:

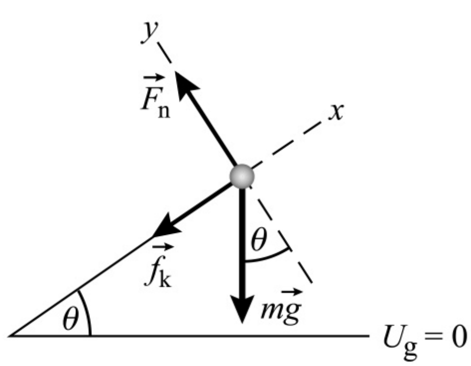
$$v_f = \sqrt{\frac{2\Delta K}{m}}$$

Substitute numerical values and evaluate v_f:

$$v_f = \sqrt{\frac{2(33.8\,\text{J})}{8\,\text{kg}}} = \boxed{2.91\,\text{m/s}}$$

***46 •**

Picture the Problem Choose $U_g = 0$ at the foot of the ramp and let the system consist of the block, ramp, and the earth. Then the kinetic energy of the block at the foot of the ramp is equal to its initial kinetic energy less the energy dissipated by friction. The block's kinetic energy at the foot of the incline is partially converted to gravitational potential energy and partially dissipated by friction as the block slides up the incline. The free-body diagram shows the forces acting on the block as it slides up the incline. Applying Newton's 2nd law to the block will allow us to determine f_k and express the energy dissipated by friction.



(*a*) Apply conservation of energy to the system while the block is moving horizontally:

$$W_{\text{ext}} = \Delta E_{\text{mech}} + \Delta E_{\text{therm}} = \Delta K + \Delta U + f\Delta s$$

or, because $\Delta U = W_{\text{ext}} = 0$,

$$0 = \Delta K + f\Delta s = K_f - K_i + f\Delta s$$

Solve for K_f:

$$K_f = K_i - f\Delta s$$

Substitute for K_f, K_i, and $f\Delta s$ to obtain:

$$\tfrac{1}{2}mv_f^2 = \tfrac{1}{2}mv_i^2 - \mu_k mg\Delta x$$

Solving for v_f yields:

$$v_f = \sqrt{v_i^2 - 2\mu_k g\Delta x}$$

Substitute numerical values and evaluate v_f:

$$v_f = \sqrt{(7\,\text{m/s})^2 - 2(0.3)(9.81\,\text{m/s}^2)(2\,\text{m})} = \boxed{6.10\,\text{m/s}}$$

(*b*) Apply conservation of energy to the system while the block is on the incline:

$$W_{ext} = \Delta E_{mech} + \Delta E_{therm} = \Delta K + \Delta U + f\Delta s$$

or, because $K_f = W_{ext} = 0$,

$$0 = -K_i + \Delta U + f\Delta s$$

Apply $\sum F_y = ma_y$ to the block when it is on the incline:

$$F_n - mg\cos\theta = 0 \Rightarrow F_n = mg\cos\theta$$

Express $f\Delta s$:

$$f\Delta s = f_k L = \mu_k F_n L = \mu_k mgL\cos\theta$$

The final potential energy of the block is:

$$U_f = mgL\sin\theta$$

Substitute for U_f, U_i, and $f\Delta s$ to obtain:

$$0 = -K_i + mgL\sin\theta + \mu_k mgL\cos\theta$$

Solving for L yields:

$$L = \frac{\tfrac{1}{2}v_i^2}{g(\sin\theta + \mu_k\cos\theta)}$$

Substitute numerical values and evaluate L:

$$L = \frac{\tfrac{1}{2}(6.10\,\text{m/s})^2}{(9.81\,\text{m/s}^2)(\sin 40° + (0.3)\cos 40°)} = \boxed{2.17\,\text{m}}$$

47 •

Picture the Problem Let the system include the block, the ramp and horizontal surface, and the earth. Given this choice, there are no external forces acting that will change the energy of the system. Because the curved ramp is frictionless, mechanical energy is conserved as the block slides down it. We can calculate its speed at the bottom of the ramp by using the law of the conservation of energy. The potential energy of the block at the top of the ramp or, equivalently, its kinetic energy at the bottom of the ramp is converted into thermal energy during its slide along the horizontal surface.

(*a*) Choosing $U_g = 0$ at point 2 and letting the numeral 1 designate the initial position of the block and the numeral 2 its position at the foot of the ramp, use conservation of energy to relate the block's potential energy at the top of the ramp to its kinetic energy at the bottom:

$$W_{ext} = \Delta E_{mech} + \Delta E_{therm}$$

or, because $W_{ext} = K_i = U_f = \Delta E_{therm} = 0$,

$$0 = \tfrac{1}{2} m v_2^2 - mg\Delta h = 0$$

Solve for v_2 to obtain:

$$v_2 = \sqrt{2g\Delta h}$$

Substitute numerical values and evaluate v_2:

$$v_2 = \sqrt{2(9.81\,\text{m/s}^2)(3\,\text{m})} = \boxed{7.67\,\text{m/s}}$$

(*b*) The energy dissipated by friction is responsible for changing the thermal energy of the system:

$$W_f + \Delta K + \Delta U = \Delta E_{therm} + \Delta K + \Delta U = 0$$

Because $\Delta K = 0$ for the slide:

$$W_f = -\Delta U = -(U_2 - U_1) = U_1$$

Substitute numerical values and evaluate W_f:

$$W_f = mg\Delta h = (2\,\text{kg})(9.81\,\text{m/s}^2)(3\,\text{m}) = \boxed{58.9\,\text{J}}$$

(*c*) The energy dissipated by friction is given by:

$$\Delta E_{therm} = f\Delta s = \mu_k mg\Delta x$$

Solve for μ_k:

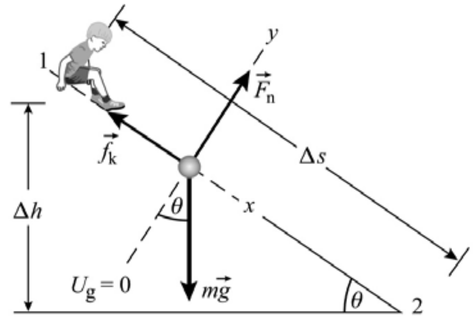
$$\mu_k = \frac{\Delta E_{therm}}{mg\Delta x}$$

Substitute numerical values and evaluate μ_k:

$$\mu_k = \frac{58.9\,\text{J}}{(2\,\text{kg})(9.81\,\text{m/s}^2)(9\,\text{m})} = \boxed{0.333}$$

48 ••

Picture the Problem Let the system consist of the earth, the girl, and the slide. Given this choice, there are no external forces doing work to change the energy of the system**.** By the time she reaches the bottom of the slide, her potential energy at the top of the slide has been converted into kinetic and thermal energy. Choose $U_g = 0$ at the bottom of the slide and denote the top and bottom of the slide as shown in the figure. We'll use the work-energy theorem with friction to relate these quantities and the forces acting on her during her slide to determine the friction force that transforms some of her initial potential energy into thermal energy.



(*a*) Express the work-energy theorem:

$$W_{ext} = \Delta K + \Delta U + \Delta E_{therm} = 0$$

Because $U_2 = K_1 = W_{ext} = 0$:

$$0 = K_2 - U_1 + \Delta E_{therm} = 0$$

or

$$\Delta E_{therm} = U_1 - K_2 = mg\Delta h - \tfrac{1}{2}mv_2^2$$

Substitute numerical values and evaluate ΔE_{therm}:

$$\Delta E_{therm} = (20\,\text{kg})(9.81\,\text{m/s}^2)(3.2\,\text{m}) - \tfrac{1}{2}(20\,\text{kg})(1.3\,\text{m/s})^2 = \boxed{611\,\text{J}}$$

(*b*) Relate the energy dissipated by friction to the kinetic friction force and the distance over which this force acts and solve for μ_k:

$$\Delta E_{therm} = f\Delta s = \mu_k F_n \Delta s$$

and

$$\mu_k = \frac{\Delta E_{therm}}{F_n \Delta s}$$

Apply $\sum F_y = ma_y$ to the girl and solve for F_n:

$$F_n - mg\cos\theta = 0 \Rightarrow F_n = mg\cos\theta$$

Referring to the figure, relate Δh to Δs and θ:

$$\Delta s = \frac{\Delta h}{\sin\theta}$$

Substitute for Δs and F_n to obtain:

$$\mu_k = \frac{\Delta E_{therm}}{mg\dfrac{\Delta h}{\sin\theta}\cos\theta} = \frac{\Delta E_{therm}\tan\theta}{mg\Delta h}$$

Substitute numerical values and evaluate μ_k:

$$\mu_k = \frac{(611\,\text{J})\tan 20°}{(20\,\text{kg})(9.81\,\text{m/s}^2)(3.2\,\text{m})} = \boxed{0.354}$$

49 ••

Picture the Problem Let the system consist of the two blocks, the shelf, and the earth. Given this choice, there are no external forces doing work to change the energy of the system. Due to the friction between the 4-kg block and the surface on which it slides, not all of the energy transformed during the fall of the 2-kg block is realized in the form of kinetic energy. We can find the energy dissipated by friction and then use the work-energy theorem with kinetic friction to find the speed of either block when they have moved the given distance.

(*a*) The energy dissipated by friction when the 2-kg block falls a distance *y* is given by:

$$\Delta E_{\text{therm}} = f\Delta s = \mu_k m_1 g y$$

Substitute numerical values and evaluate ΔE_{therm}:

$$\Delta E_{\text{therm}} = (0.35)(4\,\text{kg})(9.81\,\text{m/s}^2)y = \boxed{(13.7\,\text{N})y}$$

(*b*) From the work-energy theorem with kinetic friction we have:

$$W_{\text{ext}} = \Delta E_{\text{mech}} + \Delta E_{\text{therm}}$$

or, because $W_{\text{ext}} = 0$,

$$\Delta E_{\text{mech}} = -\Delta E_{\text{therm}} = \boxed{-(13.7\,\text{N})y}$$

(*c*) Express the total mechanical energy of the system:

$$\tfrac{1}{2}(m_1 + m_2)v^2 - m_2 g y = -\Delta E_{\text{therm}}$$

Solve for *v* to obtain:

$$v = \sqrt{\frac{2(m_2 g y - \Delta E_{\text{therm}})}{m_1 + m_2}} \qquad (1)$$

Substitute numerical values and evaluate *v*:

$$v = \sqrt{\frac{2[(2\,\text{kg})(9.81\,\text{m/s}^2)(2\,\text{m}) - (13.73\,\text{N})(2\,\text{m})]}{4\,\text{kg} + 2\,\text{kg}}} = \boxed{1.98\,\text{m/s}}$$

***50** ••

Picture the Problem Let the system consist of the particle, the table, and the earth. Then $W_{\text{ext}} = 0$ and the energy dissipated by friction during one revolution is the change in the thermal energy of the system.

(*a*) Apply the work-energy theorem

$$W_{\text{ext}} = \Delta K + \Delta U + \Delta E_{\text{therm}}$$

with kinetic friction to obtain:

or, because $\Delta U = W_{ext} = 0$,

$$0 = \Delta K + \Delta E_{therm}$$

Substitute for ΔK_f and simplify to obtain:

$$\Delta E_{therm} = -\left(\tfrac{1}{2}mv_f^2 - \tfrac{1}{2}mv_i^2\right) = -\left[\tfrac{1}{2}m\left(\tfrac{1}{2}v_0\right)^2 - \tfrac{1}{2}m(v_0)^2\right] = \boxed{\tfrac{3}{8}mv_0^2}$$

(*b*) Relate the energy dissipated by friction to the distance traveled and the coefficient of kinetic friction:

$$\Delta E_{therm} = f\Delta s = \mu_k mg\Delta s = \mu_k mg(2\pi r)$$

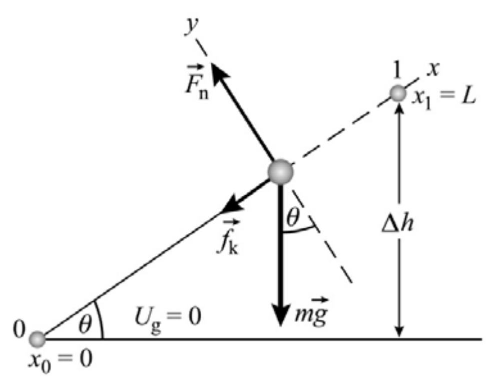
Substitute for ΔE and solve for μ_k to obtain:

$$\mu_k = \frac{\Delta E_{therm}}{2\pi mgr} = \frac{\tfrac{3}{8}mv_0^2}{2\pi mgr} = \boxed{\frac{3v_0^2}{16\pi gr}}$$

(*c*) Because it lost $\tfrac{3}{4}K_i$ in one revolution, it will only require another 1/3 revolution to lose the remaining $\tfrac{1}{4}K_i$.

51 ••

Picture the Problem The box will slow down and stop due to the dissipation of thermal energy. Let the system be the earth, the box, and the inclined plane and apply the work-energy theorem with friction. With this choice of the system, there are no external forces doing work to change the energy of the system. The free-body diagram shows the forces acting on the box when it is moving up the incline.



Apply the work-energy theorem with friction to the system:

$$W_{ext} = \Delta E_{mech} + \Delta E_{therm} = \Delta K + \Delta U + \Delta E_{therm}$$

Substitute for ΔK, ΔU, and ΔE_{therm} to obtain:

$$0 = \tfrac{1}{2}mv_1^2 - \tfrac{1}{2}mv_0^2 + mg\Delta h + \mu_k F_n L \quad (1)$$

Referring to the FBD, relate the normal force to the weight of the box and the angle of the incline:

$$F_n = mg\cos\theta$$

Relate Δh to the distance L along the

$$\Delta h = L\sin\theta$$

incline:

Substitute in equation (1) to obtain:

$$\mu_k mgL\cos\theta + \tfrac{1}{2}mv_1^2 - \tfrac{1}{2}mv_0^2 + mgL\sin\theta = 0 \quad (2)$$

Solving equation (2) for L yields:

$$L = \frac{v_0^2}{2g(\mu_k\cos\theta + \sin\theta)}$$

Substitute numerical values and evaluate L:

$$L = \frac{(3.8\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)[(0.3)\cos37° + \sin37°]} = \boxed{0.875\,\text{m}}$$

Let v_f represent the box's speed as it passes its starting point on the way down the incline. For the block's descent, equation (2) becomes:

$$\mu_k mgL\cos\theta + \tfrac{1}{2}mv_f^2 - \tfrac{1}{2}mv_1^2 - mgL\sin\theta = 0$$

Set $v_1 = 0$ (the block starts from rest at the top of the incline) and solve for v_f :

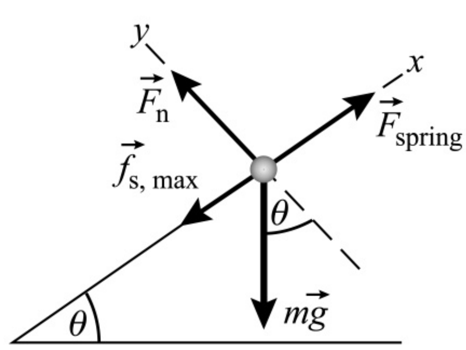
$$v_f = \sqrt{2gL(\sin\theta - \mu_k\cos\theta)}$$

Substitute numerical values and evaluate v_f:

$$v_f = \sqrt{2(9.81\,\text{m/s}^2)(0.875\,\text{m})[\sin37° - (0.3)\cos37°]} = \boxed{2.49\,\text{m/s}}$$

52 •••

Picture the Problem Let the system consist of the earth, the block, the incline, and the spring. With this choice of the system, there are no external forces doing work to change the energy of the system. The free-body diagram shows the forces acting on the block just before it begins to move. We can apply Newton's 2nd law to the block to obtain an expression for the extension of the spring at this instant. We'll apply the work-energy theorem with friction to the second part of the problem.



(*a*) Apply $\sum\vec{F} = m\vec{a}$ to the block

$$\sum F_x = F_{spring} - f_{s,max} - mg\sin\theta = 0$$

when it is on the verge of sliding: and

$$\sum F_y = F_n - mg\cos\theta = 0$$

Eliminate F_n, $f_{s,max}$, and F_{spring} between the two equations to obtain:

$$kd - \mu_s mg\cos\theta - mg\sin\theta = 0$$

Solve for and evaluate d:

$$d = \boxed{\frac{mg}{k}\left(\sin\theta + \mu_s\cos\theta\right)}$$

(b) Begin with the work-energy theorem with friction and no work being done by an external force:

$$W_{ext} = \Delta E_{mech} + \Delta E_{therm}$$
$$= \Delta K + \Delta U_g + \Delta U_s + \Delta E_{therm}$$

Because the block is at rest in both its initial and final states, $\Delta K = 0$ and:

$$\Delta U_g + \Delta U_s + \Delta E_{therm} = 0 \qquad (1)$$

Let $U_g = 0$ at the initial position of the block. Then:

$$\Delta U_g = U_{g,final} - U_{g,initial} = mgh - 0$$
$$= mgd\sin\theta$$

Express the change in the energy stored in the spring as it relaxes to its unstretched length:

$$\Delta U_s = U_{s,final} - U_{s,initial} = 0 - \tfrac{1}{2}kd^2$$
$$= -\tfrac{1}{2}kd^2$$

The energy dissipated by friction is:

$$\Delta E_{therm} = f\Delta s = -f_k d = -\mu_k F_n d$$
$$= -\mu_k mgd\cos\theta$$

Substitute in equation (1) to obtain:

$$mgd\sin\theta - \tfrac{1}{2}kd^2 - \mu_k mgd\cos\theta = 0$$

Finally, solve for μ_k:

$$\mu_k = \boxed{\tfrac{1}{2}\left(\tan\theta - \mu_s\right)}$$

Mass and Energy

53 •

Picture the Problem The intrinsic rest energy in matter is related to the mass of matter through Einstein's equation $E_0 = mc^2$.

(*a*) Relate the rest mass consumed to the energy produced and solve for and evaluate *m*:

$$E_0 = mc^2$$
$$= \left(1\times10^{-3}\text{ kg}\right)\left(3\times10^{8}\text{ m/s}\right)^2$$
$$= \boxed{9.00\times10^{13}\text{ J}}$$

(*b*) Express kW·h in joules:

$$1\text{kW}\cdot\text{h} = \left(1\times10^{3}\text{ J/s}\right)\left(1\text{h}\right)\left(3600\text{ s/h}\right)$$
$$= 3.60\times10^{6}\text{ J}$$

Convert 9×10^{13} J to kW·h:

$$9\times10^{13}\text{ J} = \left(9\times10^{13}\text{ J}\right)\left(\frac{1\text{kW}\cdot\text{h}}{3.60\times10^{6}\text{ J}}\right)$$
$$= 2.50\times10^{7}\text{ kW}\cdot\text{h}$$

Determine the price of the electrical energy:

$$\text{Price} = \left(2.50\times10^{7}\text{ kW}\cdot\text{h}\right)\left(\frac{\$0.10}{\text{kW}\cdot\text{h}}\right)$$
$$= \boxed{\$2.5\times10^{6}}$$

(*c*) Relate the energy consumed to its rate of consumption and the time and solve for the latter:

$$E = Pt$$

and

$$t = \frac{E}{P} = \frac{9\times10^{13}\text{ J}}{100\text{ W}}$$
$$= \boxed{9\times10^{11}\text{ s} = 28{,}500\text{ y}}$$

54 •

Picture the Problem We can use the equation expressing the equivalence of energy and matter, $E = mc^2$, to find the mass equivalent of the energy from the explosion.

Solve $E = mc^2$ for *m*:

$$m = \frac{E}{c^2}$$

Substitute numerical values and evaluate *m*:

$$m = \frac{5\times10^{12}\text{ J}}{\left(2.998\times10^{8}\text{ m/s}\right)^2}$$
$$= \boxed{5.56\times10^{-5}\text{ kg}}$$

55 •

Picture the Problem The intrinsic rest energy in matter is related to the mass of matter through Einstein's equation $E_0 = mc^2$.

Relate the rest mass of a muon to its rest energy:

$$m_0 = \frac{E}{c^2}$$

Express 1 MeV in joules:

$1\text{ MeV} = 1.6\times10^{-13}\text{ J}$

Substitute numerical values and evaluate m_0:

$$m_0 = \frac{(105.7\,\text{MeV})(1.6\times10^{-13}\text{ J/MeV})}{(3\times10^{8}\text{ m/s})^2} = \boxed{1.88\times10^{-28}\text{ kg}}$$

***56** •

Picture the Problem We can differentiate the mass-energy equation to obtain an expression for the rate at which the black hole gains energy.

Using the mass-energy relationship, express the energy radiated by the black hole:

$$E = 0.01mc^2$$

Differentiate this expression to obtain an expression for the rate at which the black hole is radiating energy:

$$\frac{dE}{dt} = \frac{d}{dt}\left[0.01mc^2\right] = 0.01c^2\frac{dm}{dt}$$

Solve for dm/dt:

$$\frac{dm}{dt} = \frac{dE/dt}{0.01c^2}$$

Substitute numerical values and evaluate dm/dt:

$$\frac{dm}{dt} = \frac{4\times10^{31}\text{ watt}}{(0.01)(2.998\times10^{8}\text{ m/s})^2} = \boxed{4.45\times10^{16}\text{ kg/s}}$$

57 •

Picture the Problem The number of reactions per second is given by the ratio of the power generated to the energy released per reaction. The number of reactions that must take place to produce a given amount of energy is the ratio of the energy per second (power) to the energy released per second.

In Example 7-15 it is shown that the energy per reaction is 17.59 MeV. Convert this energy to joules:

$$17.59\,\text{MeV} = (17.59\,\text{MeV})\times(1.6\times10^{-19}\text{ J/eV}) = 28.1\times10^{-13}\text{ J}$$

The number of reactions per second is:

$$\frac{1000\,\text{J/s}}{28.1\times10^{-13}\text{ J/reaction}} = \boxed{3.56\times10^{14}\text{ reactions/s}}$$

58 •

Picture the Problem The energy required for this reaction is the difference between the rest energy of ^{4}He and the sum of the rest energies of ^{3}He and a neutron.

Express the reaction: $^{4}\text{He} \rightarrow {}^{3}\text{He} + \text{n}$

The rest energy of a neutron (Table 7-1) is: 939.573 MeV

The rest energy of ^{4}He (Example 7-15) is: 3727.409 MeV

The rest energy of ^{3}He is: 2808.432 MeV

Substitute numerical values to find the difference in the rest energy of ^{4}He and the sum of the rest energies of ^{3}He and n:

$$E = [3727.409 - (2808.41 + 939.573)]\text{ MeV} = \boxed{20.574\,\text{MeV}}$$

59 •

Picture the Problem The energy required for this reaction is the difference between the rest energy of a neutron and the sum of the rest energies of a proton and an electron.

The rest energy of a proton (Table 7-1) is: 938.280 MeV

The rest energy of an electron (Table 7-1) is: 0.511 MeV

The rest energy of a neutron (Table 7-1) is: 939.573 MeV

Substitute numerical values to find the difference in the rest energy of a neutron and the sum of the rest energies of a positron and an electron:

$$E = [939.573 - (938.280 + 0.511)]\text{ MeV} = \boxed{0.782\,\text{MeV}}$$

60 ••

Picture the Problem The reaction is ${}^{2}\text{H} + {}^{2}\text{H} \rightarrow {}^{4}\text{He} + E$. The energy released in this reaction is the difference between twice the rest energy of ^{2}H and the rest energy of ^{4}He.

The number of reactions that must take place to produce a given amount of energy is the ratio of the energy per second (power) to the energy released per reaction.

(*a*) The rest energy of ^{4}He (Example 7-14) is:

$$3727.409\text{ MeV}$$

The rest energy of a deuteron, ^{2}H, (Table 7-1) is:

$$1875.628\text{ MeV}$$

The energy released in the reaction is:

$$E = [2(1875.628) - 3727.409]\text{ MeV}$$
$$= \boxed{23.847\text{ MeV} = 3.816\times10^{-12}\text{ J}}$$

(*b*) The number of reactions per second is:

$$\frac{1000\text{ J/s}}{3.816\times10^{-12}\text{ J/reaction}}$$
$$= \boxed{2.62\times10^{14}\text{ reactions/s}}$$

61 ••

Picture the Problem The annual consumption of matter by the fission plant is the ratio of its annual energy output to the square of the speed of light. The annual consumption of coal in a coal-burning power plant is the ratio of its annual energy output to energy per unit mass of the coal.

(*a*) Express *m* in terms of *E*:

$$m = \frac{E}{c^2}$$

Assuming an efficiency of 33 percent, find the energy produced annually:

$$E = 3P\Delta t = 3(3\times10^9\text{ J/s})(1\text{ y})$$
$$= 3(3\times10^9\text{ J/s})(3600\text{ s/h})$$
$$\times(24\text{ h/d})(365.24\text{ d})$$
$$= 2.84\times10^{17}\text{ J}$$

Substitute to obtain:

$$m = \frac{2.84\times10^{17}\text{ J}}{(3\times10^8\text{ m/s})^2} = \boxed{3.16\text{ kg}}$$

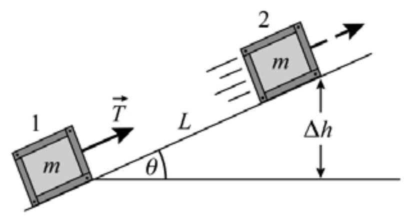
(*b*) Assuming an efficiency of 38 percent, express the mass of coal required in terms of the annual energy production and the energy released per kilogram:

$$m_{\text{coal}} = \frac{E_{\text{annual}}}{0.38(E/m)} = \frac{9.47\times10^{16}\text{ J}}{0.38(3.1\times10^7\text{ J/kg})}$$
$$= \boxed{8.04\times10^9\text{ kg}}$$

General Problems

***62 ••**

Picture the Problem Let the system consist of the block, the earth, and the incline. Then the tension in the string is an external force that will do work to change the energy of the system. Because the incline is frictionless; the work done by the tension in the string as it displaces the block on the incline is equal to the sum of the changes in the kinetic and gravitational potential energies.



Relate the work done by the tension force to the changes in the kinetic and gravitational potential energies of the block:

$$W_{\text{tension force}} = W_{\text{ext}} = \Delta U + \Delta K$$

Referring to the figure, express the change in the potential energy of the block as it moves from position 1 to position 2:

$$\Delta U = mg\Delta h = mgL\sin\theta$$

Because the block starts from rest:

$$\Delta K = K_2 = \tfrac{1}{2}mv^2$$

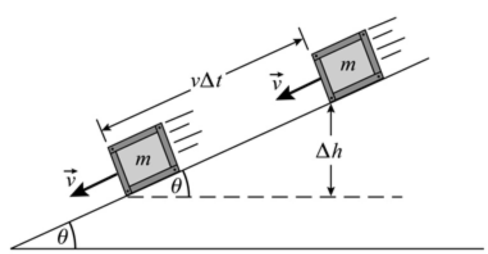
Substitute to obtain:

$$W_{\text{tension force}} = mgL\sin\theta + \tfrac{1}{2}mv^2$$

and $\boxed{\text{(c) is correct.}}$

63 ••

Picture the Problem Let the system include the earth, the block, and the inclined plane. Then there are no external forces to do work on the system and $W_{\text{ext}} = 0$. Apply the work-energy theorem with friction to find an expression for the energy dissipated by friction.



Express the work-energy theorem with friction:

$$W_{\text{ext}} = \Delta K + \Delta U + \Delta E_{\text{therm}} = 0$$

Because the velocity of the block is constant, $\Delta K = 0$ and:

$$\Delta E_{\text{therm}} = -\Delta U = -mg\Delta h$$

In time Δt the block slides a distance $v\Delta t$. From the figure:

$$\Delta h = v\Delta t \sin\theta$$

Substitute to obtain:

$$\Delta E_{\text{therm}} = -mgv\Delta t \sin\theta$$

and $\boxed{(b) \text{ is correct.}}$

64 •

Picture the Problem Let the system include the earth and the box. Then the applied force is external to the system and does work on the system in compressing the spring. This work is stored in the spring as potential energy.

Express the work-energy theorem:

$$W_{\text{ext}} = \Delta K + \Delta U_{\text{g}} + \Delta U_{\text{s}} + \Delta E_{\text{therm}}$$

Because $\Delta K = \Delta U_{\text{g}} = \Delta E_{\text{therm}} = 0$:

$$W_{\text{ext}} = \Delta U_{\text{s}}$$

Substitute for W_{ext} and ΔU_{s}:

$$Fx = \tfrac{1}{2}kx^2$$

Solve for x:

$$x = \frac{2F}{k}$$

Substitute numerical values and evaluate x:

$$x = \frac{2(70\text{ N})}{6800\text{ N/m}} = \boxed{2.06\text{ cm}}$$

***65** •

Picture the Problem The solar constant is the average energy per unit area and per unit time reaching the upper atmosphere. This physical quantity can be thought of as the power per unit area and is known as *intensity*.

Letting I_{surface} represent the intensity of the solar radiation at the surface of the earth, express I_{surface} as a function of power and the area on which this energy is incident:

$$I_{\text{surface}} = \frac{P}{A} = \frac{\Delta E/\Delta t}{A}$$

Solve for ΔE:

$$\Delta E = I_{\text{surface}} A\Delta t$$

Substitute numerical values and evaluate ΔE:

$$\Delta E = (1\,\text{kW/m}^2)(2\,\text{m}^2)(8\,\text{h})(3600\,\text{s/h}) = \boxed{57.6\,\text{MJ}}$$

66 ••

Picture the Problem The luminosity of the sun (or of any other object) is the product of the power it radiates per unit area and its surface area. If we let L represent the sun's luminosity, I the power it radiates per unit area (also known as the solar constant or the intensity of its radiation), and A its surface area, then $L = IA$. We can estimate the solar lifetime by dividing the number of hydrogen nuclei in the sun by the rate at which they are being transformed into energy.

(*a*) Express the total energy the sun radiates every second in terms of the solar constant:

$$L = IA$$

Letting R represent its radius, express the surface area of the sun:

$$A = 4\pi R^2$$

Substitute to obtain:

$$L = 4\pi R^2 I$$

Substitute numerical values and evaluate L:

$$L = 4\pi (1.5\times10^{11}\,\text{m})^2 (1.35\,\text{kW/m}^2) = \boxed{3.82\times10^{26}\,\text{watt}}$$

Note that this result is in good agreement with the value given in the text of 3.9×10^{26} watt.

(*b*) Express the solar lifetime in terms of the mass of the sun and the rate at which its mass is being converted to energy:

$$t_{\text{solar}} = \frac{N_{\text{H nuclei}}}{\Delta n/\Delta t} = \frac{M/m}{\Delta n/\Delta t}$$

where M is the mass of the sun, m the mass of a hydrogen nucleus, and n is the number of nuclei used up.

Substitute numerical values to obtain:

$$t_{\text{solar}} = \frac{\dfrac{1.99\times10^{30}\,\text{kg}}{1.67\times10^{-27}\,\text{kg/H nucleus}}}{\Delta n/\Delta t} = \frac{1.19\times10^{57}\,\text{H nuclei}}{\Delta n/\Delta t}$$

For each reaction, 4 hydrogen nuclei are "used up"; so:

$$\frac{\Delta n}{\Delta t} = \frac{4(3.82\times10^{26}\,\text{J/s})}{4.27\times10^{-12}\,\text{J}} = 3.57\times10^{38}\,\text{s}^{-1}$$

Because we've assumed that the sun will continue burning until roughly 10% of its hydrogen fuel is used up, the total solar lifetime should be:

$$t_{\text{solar}} = 0.1\left(\frac{1.19\times10^{57}\ \text{H nuclei}}{3.57\times10^{38}\ \text{s}^{-1}}\right)$$
$$= 3.33\times10^{17}\ \text{s} = \boxed{1.06\times10^{10}\ \text{y}}$$

67 •

Picture the Problem Let the system include the earth and the *Spirit of America*. Then there are no external forces to do work on the car and $W_{\text{ext}} = 0$. We can use the work-energy theorem to relate the coefficient of kinetic friction to the given information. A constant-acceleration equation will yield the car's velocity when 60 s have elapsed.

(*a*) Apply the work-energy theorem with friction to relate the coefficient of kinetic friction μ_k to the initial and final kinetic energies of the car:

$$\tfrac{1}{2}mv^2 - \tfrac{1}{2}mv_0^2 + \mu_k mg\Delta s = 0$$

or, because $v = 0$,

$$-\tfrac{1}{2}mv_0^2 + \mu_k mg\Delta s = 0$$

Solve for μ_k:

$$\mu_k = \frac{v^2}{2g\Delta s}$$

Substitute numerical values and evaluate μ_k:

$$\mu_k = \frac{\left[(708\,\text{km/h})(1\,\text{h}/3600\,\text{s})\right]^2}{2\left(9.81\,\text{m/s}^2\right)(9.5\,\text{km})} = \boxed{0.208}$$

(*b*) Express the kinetic energy of the car:

$$K = \tfrac{1}{2}mv^2 \qquad (1)$$

Using a constant-acceleration equation, relate the speed of the car to its acceleration, initial speed, and the elapsed time:

$$v = v_0 + a\Delta t$$

Express the braking force acting on the car:

$$F_{\text{net}} = -f_k = -\mu_k mg = ma$$

Solve for a:

$$a = -\mu_k g$$

Substitute for a to obtain:

$$v = v_0 - \mu_k g\Delta t$$

Substitute in equation (1) to obtain:

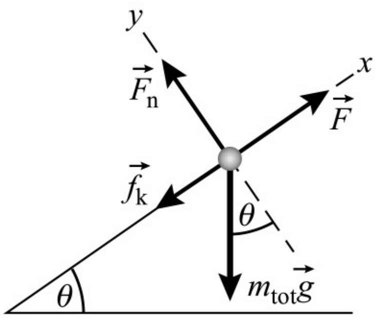
$$K = \tfrac{1}{2}m\left(v_0 - \mu_k g\Delta t\right)^2$$

Substitute numerical values and evaluate K:

$$K = \tfrac{1}{2}(1250\,\text{kg})\left[708\times10^{3}\ \text{m/h} - (0.208)(9.81\,\text{m/s}^2)(60\,\text{s})\right]^2 = \boxed{3.45\,\text{MJ}}$$

68 ••

Picture the Problem The free-body diagram shows the forces acting on the skiers as they are towed up the slope at constant speed. Because the power required to move them is $\vec{F}\cdot\vec{v}$, we need to find F as a function of m_{tot}, θ, and μ_k. We can apply Newton's 2nd law to obtain such a function.



Express the power required as a function of force on the skiers and their speed:

$$P = Fv \qquad (1)$$

Apply $\sum\vec{F} = m\vec{a}$ to the skiers:

$$\sum F_x = F - f_k - m_{tot}g\sin\theta = 0$$

and

$$\sum F_y = F_n - m_{tot}g\cos\theta = 0$$

Eliminate $f_k = \mu_k F_n$ and F_n between the two equations and solve for F:

$$F = m_{tot}g\sin\theta + \mu_k m_{tot}g\cos\theta$$

Substitute in equation (1) to obtain:

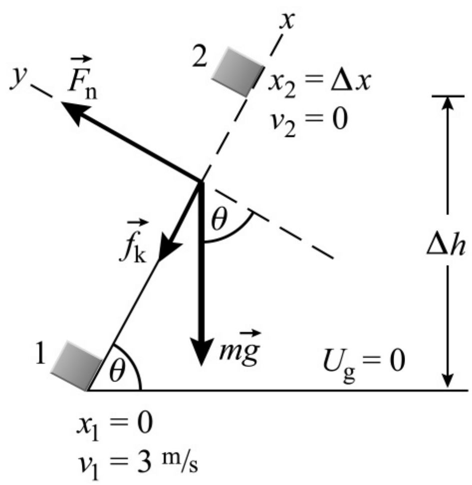
$$P = (m_{tot}g\sin\theta + \mu_k m_{tot}g\cos\theta)v$$
$$= m_{tot}gv(\sin\theta + \mu_k\cos\theta)$$

Substitute numerical values and evaluate P:

$$P = 80(75\,\text{kg})(9.81\,\text{m/s}^2)(2.5\,\text{m/s})[\sin15° + (0.06)\cos15°] = \boxed{46.6\,\text{kW}}$$

69 ••

Picture the Problem The free-body diagram for the box is superimposed on the pictorial representation shown to the right. The work done by friction slows and momentarily stops the box as it slides up the incline. The box's speed when it returns to bottom of the incline will be less than its speed when it started up the incline due to the energy dissipated by friction while it was in motion. Let the system include the box, the earth, and the incline. Then $W_{ext} = 0$. We can use the work-energy theorem with friction to solve the several parts of this problem.



(*a*) From the FBD we can see that the forces acting on the box are the normal force exerted by the inclined plane, a kinetic friction force, and the gravitational force (the weight of the box) exerted by the earth.

(*b*) Apply the work-energy theorem with friction to relate the distance Δx the box slides up the incline to its initial kinetic energy, its final potential energy, and the work done against friction:

$$-\tfrac{1}{2}mv_1^2 + mg\Delta h + \mu_k mg\Delta x\cos\theta = 0$$

Referring to the figure, relate Δh to Δx to obtain:

$$\Delta h = \Delta x\sin\theta$$

Substitute for Δh to obtain:

$$-\tfrac{1}{2}mv_1^2 + mg\Delta x\sin\theta + \mu_k mg\Delta x\cos\theta = 0$$

Solve for Δx:

$$\Delta x = \frac{v_1^2}{2g(\sin\theta + \mu_k\cos\theta)}$$

Substitute numerical values and evaluate Δx:

$$\Delta x = \frac{(3\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)[\sin 60° + (0.3)\cos 60°]} = \boxed{0.451\,\text{m}}$$

(*c*) Express and evaluate the energy dissipated by friction:

$$\Delta E_{\text{therm}} = f_k \Delta x = \mu_k mg\Delta x\cos\theta$$
$$= (0.3)(2\,\text{kg})(9.81\,\text{m/s}^2)(0.451\,\text{m})\cos 60° = \boxed{1.33\,\text{J}}$$

(*d*) Use the work-energy theorem with friction to obtain:

$$W_{\text{ext}} = \Delta K + \Delta U + \Delta E_{\text{therm}} = 0$$
or
$$K_1 - K_2 + U_1 - U_2 + \Delta E_{\text{therm}} = 0$$

Because $K_2 = U_1 = 0$ we have:

$$K_1 - U_2 + \Delta E_{\text{therm}} = 0$$
or
$$\tfrac{1}{2}mv_1^2 - mg\Delta x\sin\theta + \mu_k mg\Delta x\cos\theta = 0$$

Solve for v_1:

$$v_1 = \sqrt{2g\Delta x(\sin\theta - \mu_k\cos\theta)}$$

Substitute numerical values and evaluate v_1:

$$v_1 = \sqrt{2(9.81\,\text{m/s}^2)(0.451\,\text{m})[\sin 60° - (0.3)\cos 60°]} = \boxed{2.52\,\text{m/s}}$$

***70 •**

Picture the Problem The power provided by a motor that is delivering sufficient energy to exert a force *F* on a load which it is moving at a speed *v* is *Fv*.

The power provided by the motor is given by:

$$P = Fv$$

Because the elevator is ascending with constant speed, the tension in the support cable(s) is:

$$F = (m_{\text{elev}} + m_{\text{load}})g$$

Substitute for *F* to obtain:

$$P = (m_{\text{elev}} + m_{\text{load}})gv$$

Substitute numerical values and evaluate *P*:

$$P = (2000\,\text{kg})(9.81\,\text{m/s}^2)(2.3\,\text{m/s}) = \boxed{45.1\,\text{kW}}$$

71 ••

Picture the Problem The power a motor must provide to exert a force F on a load that it is moving at a speed v is Fv. The counterweight does negative work and the power of the motor is reduced from that required with no counterbalance.

The power provided by the motor is given by:

$$P = Fv$$

Because the elevator is counterbalanced and ascending with constant speed, the tension in the support cable(s) is:

$$F = (m_{\text{elev}} + m_{\text{load}} - m_{\text{cw}})g$$

Substitute and evaluate P:

$$P = (m_{\text{elev}} + m_{\text{load}} - m_{\text{cw}})gv$$

Substitute numerical values and evaluate P:

$$P = (500\,\text{kg})(9.81\,\text{m/s}^2)(2.3\,\text{m/s}) = \boxed{11.3\,\text{kW}}$$

Without a load:

$$F = (m_{\text{elev}} - m_{\text{cw}})g$$

and

$$P = (m_{\text{elev}} - m_{\text{cw}})gv = (-300\,\text{kg})(9.81\,\text{m/s}^2)(2.3\,\text{m/s}) = \boxed{-6.77\,\text{kW}}$$

72 ••

Picture the Problem We can use the work-energy theorem with friction to describe the energy transformation within the dart-spring-air-earth system. With this choice of the system, there are no external forces to do work on the system; i.e., $W_{\text{ext}} = 0$. Choose $U_{\text{g}} = 0$ at the elevation of the dart on the compressed spring. The energy initially stored in the spring is transformed into gravitational potential energy and thermal energy. During the dart's descent, its gravitational potential energy is transformed into kinetic energy and thermal energy.

Apply conservation of energy during the dart's ascent:

$$W_{\text{ext}} = \Delta K + \Delta U + \Delta E_{\text{therm}} = 0$$

or, because $\Delta K = 0$,

$$U_{\text{g,f}} - U_{\text{g,i}} + U_{\text{s,f}} - U_{\text{s,i}} + \Delta E_{\text{therm}} = 0$$

Because $U_{\text{g,i}} = U_{\text{s,f}} = 0$:

$$U_{\text{g,f}} - U_{\text{s,i}} + \Delta E_{\text{therm}} = 0$$

Substitute for $U_{g,i}$ and $U_{s,f}$ and solve for ΔE_{therm}:

$$\Delta E_{therm} = U_{s,i} - U_{g,f} = \tfrac{1}{2}kx^2 - mgh$$

Substitute numerical values and evaluate ΔE_{therm}:

$$\begin{aligned}\Delta E_{therm} &= \tfrac{1}{2}(5000\,\text{N/m})(0.03\,\text{m})^2 \\ &\quad - (0.007\,\text{kg})(9.81\,\text{m/s}^2)(24\,\text{m}) \\ &= \boxed{0.602\,\text{J}}\end{aligned}$$

Apply conservation of energy during the dart's descent:

$$W_{ext} = \Delta K + \Delta U + \Delta E_{therm} = 0$$

or, because $K_i = U_{g,f} = 0$,

$$K_f - U_{g,i} + \Delta E_{therm} = 0$$

Substitute for K_f and $U_{g,i}$ to obtain:

$$\tfrac{1}{2}mv_f^2 - mgh + \Delta E_{therm} = 0$$

Solve for v_f:

$$v_f = \sqrt{\frac{2(mgh - \Delta E_{therm})}{m}}$$

Substitute numerical values and evaluate v_f:

$$v_f = \sqrt{\frac{2\left[(0.007\,\text{kg})(9.81\,\text{m/s}^2)(24\,\text{m}) - 0.602\,\text{J}\right]}{0.007\,\text{kg}}} = \boxed{17.3\,\text{m/s}}$$

***73 ••**

Picture the Problem Let the system consist of the earth, rock and air. Given this choice, there are no external forces to do work on the system and $W_{ext} = 0$. Choose $U_g = 0$ to be where the rock begins its upward motion. The initial kinetic energy of the rock is partially transformed into potential energy and partially dissipated by air resistance as the rock ascends. During its descent, its potential energy is partially transformed into kinetic energy and partially dissipated by air resistance.

(*a*) Using the definition of kinetic energy, calculate the initial kinetic energy of the rock:

$$K_i = \tfrac{1}{2}mv_i^2 = \tfrac{1}{2}(2\,\text{kg})(40\,\text{m/s})^2 = \boxed{1.60\,\text{kJ}}$$

(*b*) Apply the work-energy theorem with friction to relate the energies of the system as the rock ascends:

$$\Delta K + \Delta U + \Delta E_{therm} = 0$$

Because $K_f = 0$:

$$-K_i + \Delta U + \Delta E_{therm} = 0$$

and

$$\Delta E_{therm} = K_i - \Delta U$$

Substitute numerical values and evaluate ΔE_{therm}:

$$\Delta E_{\text{therm}} = 1600\,\text{J} - (2\,\text{kg})(9.81\,\text{m/s}^2)(50\,\text{m}) = \boxed{619\,\text{J}}$$

(*c*) Apply the work-energy theorem with friction to relate the energies of the system as the rock descends:

$$\Delta K + \Delta U + 0.7\Delta E_{\text{therm}} = 0$$

Because $K_\text{i} = U_\text{f} = 0$:

$$K_\text{f} - U_\text{i} + 0.7\Delta E_{\text{therm}} = 0$$

Substitute for the energies to obtain:

$$\tfrac{1}{2}mv_\text{f}^2 - mgh + 0.7\Delta E_{\text{therm}} = 0$$

Solve for v_f:

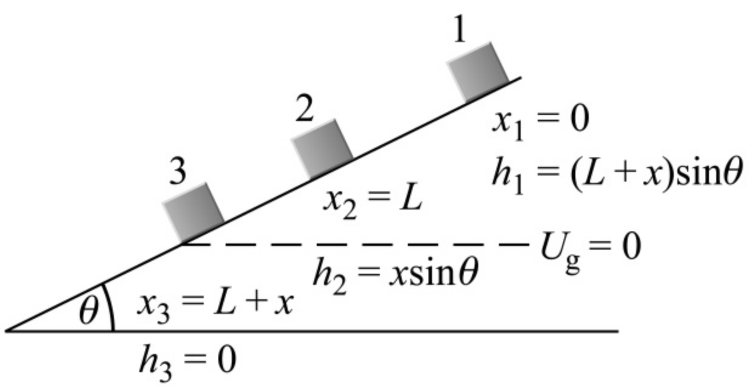
$$v_\text{f} = \sqrt{2gh - \frac{1.4\Delta E_{\text{therm}}}{m}}$$

Substitute numerical values and evaluate v_f:

$$v_\text{f} = \sqrt{2(9.81\,\text{m/s}^2)(50\,\text{m}) - \frac{1.4(619\,\text{J})}{2\,\text{kg}}} = \boxed{23.4\,\text{m/s}}$$

74 ••

Picture the Problem Let the distance the block slides before striking the spring be *L*. The pictorial representation shows the block at the top of the incline (1), just as it strikes the spring (2), and the block against the fully compressed spring (3). Let the block, spring, and the earth comprise the system. Then $W_{\text{ext}} = 0$. Let $U_g = 0$ where the spring is at maximum compression. We can apply the work-energy theorem to relate the energies of the system as it evolves from state 1 to state 3.



Express the work-energy theorem:

$$\Delta K + \Delta U_\text{g} + \Delta U_\text{s} = 0$$

or

$$\Delta K + U_{\text{g},3} - U_{\text{g},1} + U_{\text{s},3} - U_{\text{s},1} = 0$$

Because $\Delta K = U_{g,3} = U_{s,1} = 0$: $$-U_{g,1} + U_{s,3} = 0$$

Substitute for each of these energy terms to obtain: $$-mgh_1 + \tfrac{1}{2}kx^2 = 0$$

Substitute for h_3 and h_1: $$-mg(L + x)\sin\theta + \tfrac{1}{2}kx^2 = 0$$

Rewrite this equation explicitly as a quadratic equation: $$x^2 - \frac{2mg\sin\theta}{k}x - \frac{2mgL\sin\theta}{k} = 0$$

Solve this quadratic equation to obtain:

$$x = \boxed{\frac{mg}{k}\sin\theta + \sqrt{\left(\frac{mg}{k}\right)^2 \sin^2\theta + \frac{2mgL}{k}\sin\theta}}$$

Note that the negative sign between the two terms leads to a non-physical solution.

***75** •

Picture the Problem We can find the work done by the girder on the slab by calculating the change in the potential energy of the slab.

(*a*) Relate the work the girder does on the slab to the change in potential energy of the slab: $$W = \Delta U = mg\Delta h$$

Substitute numerical values and evaluate *W*: $$W = (1.5\times10^4\ \text{kg})(9.81\ \text{m/s}^2)(0.001\ \text{m}) = \boxed{147\ \text{J}}$$

(*b*) The energy is transferred to the girder from its surroundings, which are warmer than the girder. As the temperature of the girder rises, the atoms in the girder vibrate with a greater average kinetic energy, leading to a larger average separation, which causes the girder's expansion.

76 ••

Picture the Problem The average power delivered by the car's engine is the rate at which it changes the car's energy. Because the car is slowing down as it climbs the hill, its potential energy increases and its kinetic energy decreases.

Express the average power delivered by the car's engine: $$P_{av} = \frac{\Delta E}{\Delta t}$$

Express the increase in the car's mechanical energy:

$$\Delta E = \Delta K + \Delta U$$
$$= K_{top} - K_{bot} + U_{top} - U_{bot}$$
$$= \tfrac{1}{2}mv_{top}^2 - \tfrac{1}{2}mv_{bot}^2 + mg\Delta h$$
$$= \tfrac{1}{2}m\left(v_{top}^2 - v_{bot}^2 + 2g\Delta h\right)$$

Substitute numerical values and evaluate ΔE:

$$\Delta E = \tfrac{1}{2}(1500\,\text{kg})\left[(10\,\text{m/s})^2 - (24\,\text{m/s})^2 + 2(9.81\,\text{m/s}^2)(120\,\text{m})\right] = 1.41\,\text{MJ}$$

Assuming that the acceleration of the car is constant, find its average speed during this climb:

$$v_{av} = \frac{v_{top} + v_{bot}}{2} = 17\,\text{m/s}$$

Using the v_{av}, find the time it takes the car to climb the hill:

$$\Delta t = \frac{\Delta s}{v_{av}} = \frac{2000\,\text{m}}{17\,\text{m/s}} = 118\,\text{s}$$

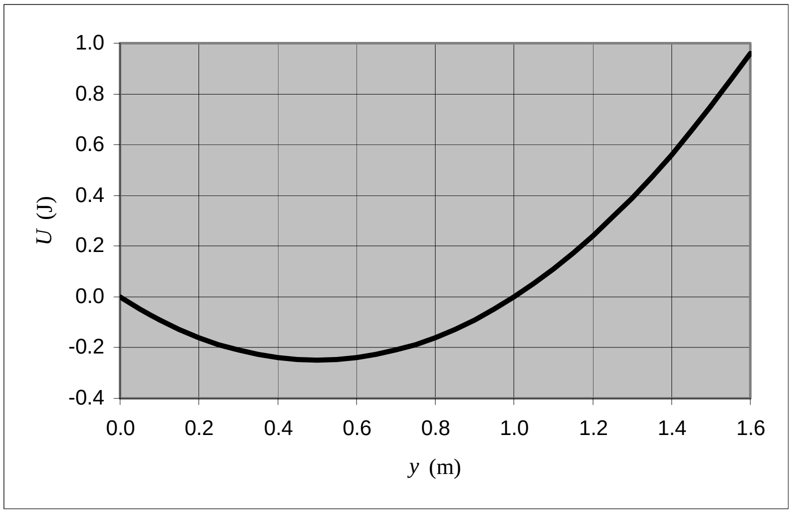
Substitute to determine P_{av}:

$$P_{av} = \frac{1.41\,\text{MJ}}{118\,\text{s}} = \boxed{11.9\,\text{kW}}$$

***77 ••**

Picture the Problem Given the potential energy function as a function of *y*, we can find the net force acting on a given system from $F = -dU/dy$. The maximum extension of the spring; i.e., the lowest position of the mass on its end, can be found by applying the work-energy theorem. The equilibrium position of the system can be found by applying the work-energy theorem with friction … as can the amount of thermal energy produced as the system oscillates to its equilibrium position.

(*a*) The graph of *U* as a function of *y* is shown to the right. Because *k* and *m* are not specified, *k* has been set equal to 2 and *mg* to 1. The spring is unstretched when $y = y_0 = 0$. Note that the minimum value of *U* (a position of stable equilibrium) occurs near $y = 5$ m.



(*b*) Evaluate the negative of the derivative of U with respect to y:

$$F = -\frac{dU}{dy} = -\frac{d}{dy}\left(\tfrac{1}{2}ky^2 - mgy\right)$$
$$= \boxed{-ky + mg}$$

(*c*) Apply conservation of energy to the movement of the mass from y = 0 to $y = y_{max}$:

$$\Delta K + \Delta U + \Delta E_{therm} = 0$$

Because $\Delta K = 0$ (the object starts from rest and is momentarily at rest at $y = y_{max}$) and $\Delta E_{therm} = 0$ (no friction), it follows that:

$$\Delta U = U(y_{max}) - U(0) = 0$$

Because $U(0) = 0$:

$$U(y_{max}) = 0 \Rightarrow \tfrac{1}{2}ky_{max}^2 - mgy_{max} = 0$$

Solve for y_{max}:

$$y_{max} = \boxed{\frac{2mg}{k}}$$

(*d*) Express the condition of F at equilibrium and solve for y_{eq}:

$$F_{eq} = 0 \Rightarrow -ky_{eq} + mg = 0$$

and

$$y_{eq} = \boxed{\frac{mg}{k}}$$

(*e*) Apply the conservation of energy to the movement of the mass from y = 0 to $y = y_{eq}$ and solve for ΔE_{therm}:

$$\Delta K + \Delta U + \Delta E_{therm} = 0$$

or, because $\Delta K = 0$.

$$\Delta E_{therm} = -\Delta U = U_i - U_f$$

Because $U_i = U(0) = 0$: $\Delta E_{therm} = -U_f = -\left(\frac{1}{2}ky_{eq}^2 - mgy_{eq}\right)$

Substitute for y_{eq} and simplify to obtain: $\Delta E_{therm} = \boxed{\dfrac{m^2g^2}{2k}}$

78 ••

Picture the Problem The energy stored in the compressed spring is initially transformed into the kinetic energy of the signal flare and then into gravitational potential energy and thermal energy as the flare climbs to its maximum height. Let the system contain the earth, the air, and the flare so that $W_{ext} = 0$. We can use the work-energy theorem with friction in the analysis of the energy transformations during the motion of the flare.

(*a*) The work done on the spring in compressing it is equal to the kinetic energy of the flare at launch. Therefore: $W_s = K_{i,\,flare} = \boxed{\frac{1}{2}mv_0^2}$

(*b*) Ignoring changes in gravitational potential energy (i.e., assume that the compression of the spring is small compared to the maximum elevation of the flare), apply the conservation of energy to the transformation that takes place as the spring decompresses and gives the flare its launch speed:

$$\Delta K + \Delta U_s = 0$$

or

$$K_f - K_i + U_{s,f} - U_{s,i} = 0$$

Because $K_i = \Delta U_g = U_{s,f}$: $K_f - U_{s,i} = 0$

Substitute for K_f and $U_{s,i}$: $\frac{1}{2}mv_0^2 - \frac{1}{2}kd^2 = 0$

Solve for k to obtain: $k = \boxed{\dfrac{mv_0^2}{d^2}}$

(*c*) Apply the work-energy theorem with friction to the upward trajectory of the flare:

$$\Delta K + \Delta U_g + \Delta E_{therm} = 0$$

Solve for ΔE_{therm}:

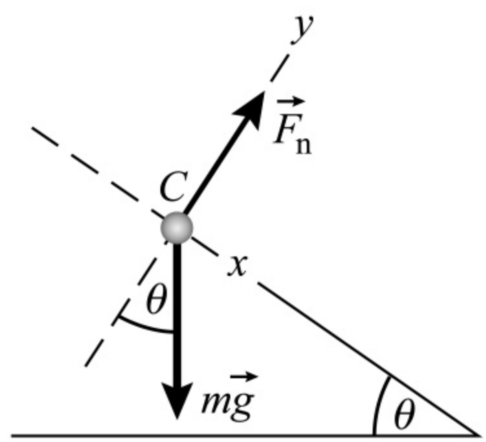
$$\Delta E_{\text{therm}} = -\Delta K - \Delta U_g = K_i - K_f + U_i - U_f$$

Because $K_f = U_i = 0$:

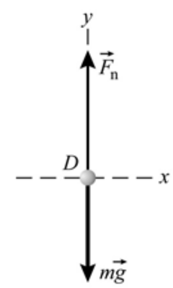
$$\Delta E_{\text{therm}} = \boxed{\tfrac{1}{2}mv_0^2 - mgh}$$

79 ••

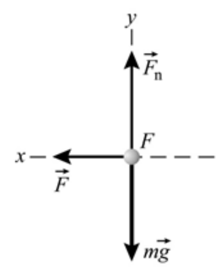
Picture the Problem Let $U_D = 0$. Choose the system to include the earth, the track, and the car. Then there are no external forces to do work on the system and change its energy and we can use Newton's 2nd law and the work-energy theorem to describe the system's energy transformations to point G … and then the work-energy theorem with friction to determine the braking force that brings the car to a stop. The free-body diagram for point C is shown to the right.



The free-body diagram for point D is shown to the right.



The free-body diagram for point F is shown to the right.



(*a*) Apply the work-energy theorem to the system's energy transformations between A and B:

$$\Delta K + \Delta U = 0$$

or

$$K_B - K_A + U_B - U_A = 0$$

If we assume that the car arrives at point B with $v_B = 0$, then:

$$-\tfrac{1}{2}mv_A^2 + mg\Delta h = 0$$

where Δh is the difference in elevation between A and B.

Solve for and evaluate Δh:

$$\Delta h = \frac{v_A^2}{2g} = \frac{(12\,\text{m/s})^2}{2(9.81\,\text{m/s}^2)} = 7.34\,\text{m}$$

The height above the ground is:

$$h + \Delta h = 10\,\text{m} + 7.34\,\text{m} = \boxed{17.3\,\text{m}}$$

(*b*) If the car just makes it to point B; i.e., if it gets there with $v_B = 0$, then the force exerted by the track on the car will be the normal force:

$$F_{\text{track on car}} = F_n = mg = (500\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{4.91\,\text{kN}}$$

(*c*) Apply $\sum F_x = ma_x$ to the car at point C (see the FBD) and solve for a:

$$mg\sin\theta = ma$$

and

$$a = g\sin\theta = (9.81\,\text{m/s}^2)\sin 30° = \boxed{4.91\,\text{m/s}^2}$$

(*d*) Apply $\sum F_y = ma_y$ to the car at point D (see the FBD) and solve for F_n:

$$F_n - mg = m\frac{v_D^2}{R}$$

and

$$F_n = mg + m\frac{v_D^2}{\text{R}}$$

Apply the work-energy theorem to the system's energy transformations between B and D:

$$\Delta K + \Delta U = 0$$

or

$$K_D - K_B + U_D - U_B = 0$$

Because $K_B = U_D = 0$:

$$K_D - U_B = 0$$

Substitute to obtain:

$$\tfrac{1}{2}mv_D^2 - mg(h + \Delta h) = 0$$

Solve for v_D^2:

$$v_D^2 = 2g(h + \Delta h)$$

Substitute to find F_n:

$$F_n = mg + m\frac{v_D^2}{\text{R}} = mg + m\frac{2g(h+\Delta h)}{R} = mg\left[1 + \frac{2(h+\Delta h)}{R}\right]$$

Substitute numerical values and evaluate F_n:

$$F_n = (500\,\text{kg})(9.81\,\text{m/s}^2)\left[1 + \frac{2(17.3\,\text{m})}{20\,\text{m}}\right]$$
$$= \boxed{13.4\,\text{kN, directed upward.}}$$

(*e*) *F* has two components at point F; one horizontal (the inward force that the track exerts) and the other vertical (the normal force). Apply $\sum \vec{F} = m\vec{a}$ to the car at point F:

$$\sum F_y = F_n - mg = 0 \Rightarrow F_n = mg$$
and
$$\sum F_x = F_c = m\frac{v_F^2}{R}$$

Express the resultant of these two forces:

$$F = \sqrt{F_c^2 + F_n^2}$$
$$= \sqrt{\left(m\frac{v_F^2}{R}\right)^2 + (mg)^2}$$
$$= m\sqrt{\frac{v_F^4}{R^2} + g^2}$$

Substitute numerical values and evaluate *F*:

$$F = (500\,\text{kg})\sqrt{\frac{(12\,\text{m/s})^4}{(30\,\text{m})^2} + (9.81\,\text{m/s}^2)^2}$$
$$= \boxed{5.46\,\text{kN}}$$

Find the angle the resultant makes with the *x* axis:

$$\theta = \tan^{-1}\left(\frac{F_n}{F_c}\right) = \tan^{-1}\left(\frac{gR}{v_F^2}\right)$$
$$= \tan^{-1}\left[\frac{(9.81\,\text{m/s}^2)(30\,\text{m})}{(12\,\text{m/s})^2}\right] = \boxed{63.9°}$$

(*f*) Apply the work-energy theorem with friction to the system's energy transformations between F and the car's stopping position:

$$-K_G + \Delta E_{\text{therm}} = 0$$
and
$$\Delta E_{\text{therm}} = K_G = \tfrac{1}{2}mv_G^2$$

The work done by friction is also given by:

$$\Delta E_{\text{therm}} = f\Delta s = F_{\text{brake}}d$$
where *d* is the stopping distance.

Equate the two expressions for ΔE_{therm} and solve for F_{brake}:

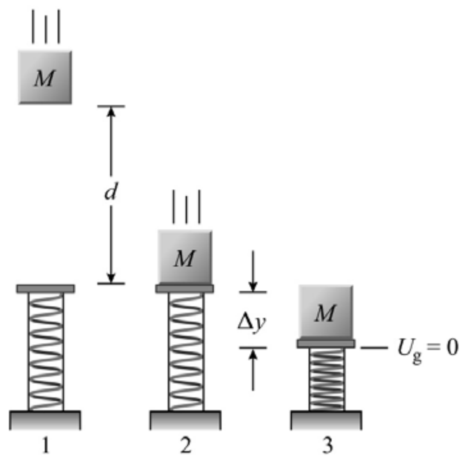
$$F_{\text{brake}} = \frac{mv_F^2}{2d}$$

Substitute numerical values and evaluate F_{brake}:

$$F_{brake} = \frac{(500\,\text{kg})(12\,\text{m/s})^2}{2(25\,\text{m})} = \boxed{1.44\,\text{kN}}$$

***80** •

Picture the Problem The rate of conversion of mechanical energy can be determined from $P = \vec{F} \cdot \vec{v}$. The pictorial representation shows the elevator moving downward just as it goes into freefall as state 1. In state 2 the elevator is moving faster and is about to strike the relaxed spring. The momentarily at rest elevator on the compressed spring is shown as state 3. Let $U_g = 0$ where the spring has its maximum compression and the system consist of the earth, the elevator, and the spring. Then $W_{ext} = 0$ and we can apply the conservation of mechanical energy to the analysis of the falling elevator and compressing spring.



(*a*) Express the rate of conversion of mechanical energy to thermal energy as a function of the speed of the elevator and braking force acting on it:

$$P = F_{braking} v_0$$

Because the elevator is moving with constant speed, the net force acting on it is zero and:

$$F_{braking} = Mg$$

Substitute for $F_{braking}$ and evaluate P:

$$\begin{aligned} P &= Mgv_0 \\ &= (2000\,\text{kg})(9.81\,\text{m/s}^2)(1.5\,\text{m/s}) \\ &= \boxed{29.4\,\text{kW}} \end{aligned}$$

(*b*) Apply the conservation of energy to the falling elevator and compressing spring:

$$\Delta K + \Delta U_g + \Delta U_s = 0$$

or

$$K_3 - K_1 + U_{g,3} - U_{g,1} + U_{s,3} - U_{s,1} = 0$$

Because $K_3 = U_{g,3} = U_{s,1} = 0$:

$$-\tfrac{1}{2} M v_0^2 - Mg(d + \Delta y) + \tfrac{1}{2} k(\Delta y)^2 = 0$$

Rewrite this equation as a quadratic equation in Δy, the maximum compression of the spring:

$$(\Delta y)^2 - \left(\frac{2Mg}{k}\right)\Delta y - \frac{M}{k}\left(2gd + v_0^2\right) = 0$$

Solve for Δy to obtain:

$$\Delta y = \frac{Mg}{k} \pm \sqrt{\frac{M^2 g^2}{k^2} + \frac{M}{k}\left(2gd + v_0^2\right)}$$

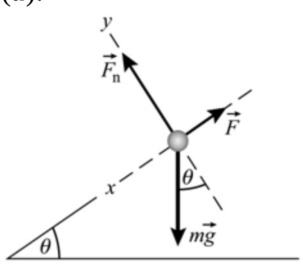
Substitute numerical values and evaluate Δy:

$$\Delta y = \frac{(2000\,\text{kg})(9.81\,\text{m/s}^2)}{1.5\times10^4\ \text{N/m}} + \sqrt{\frac{(2000\,\text{kg})^2(9.81\,\text{m/s}^2)^2}{(1.5\times10^4\ \text{N/m})^2} + \frac{2000\,\text{kg}}{1.5\times10^4\ \text{N/m}}\left[2(9.81\,\text{m/s}^2)(5\,\text{m}) + (1.5\,\text{m/s})^2\right]}$$
$$= \boxed{5.19\,\text{m}}$$

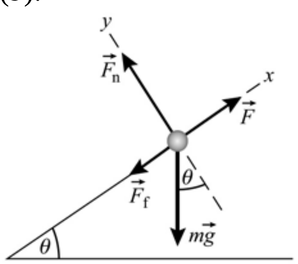
81 •

Picture the Problem We can use Newton's 2nd law to determine the force of friction as a function of the angle of the hill for a given constant speed. The power output of the engine is given by $P = \vec{F}_\text{f}\cdot\vec{v}$.

FBD for (*a*):



FBD for (*b*):



(*a*) Apply $\sum F_x = ma_x$ to the car:

$$mg\sin\theta - F_\text{f} = 0 \Rightarrow F_\text{f} = mg\sin\theta$$

Evaluate F_f for the two speeds:

$$F_{20} = (1000\,\text{kg})(9.81\,\text{m/s}^2)\sin 2.87° = \boxed{491\,\text{N}}$$

and

$$F_{30} = (1000\,\text{kg})(9.81\,\text{m/s}^2)\sin 5.74° = \boxed{981\,\text{N}}$$

(*b*) Express the power an engine must deliver on a level road in order

$$P = F_f v$$

$$P_{20} = (491\,\text{N})(20\,\text{m/s}) = \boxed{9.82\,\text{kW}}$$

to overcome friction loss and evaluate this expression for v = 20 m/s and 30 m/s:

and

$$P_{30} = (981\,\text{N})(30\,\text{m/s}) = \boxed{29.4\,\text{kW}}$$

(c) Apply $\sum F_x = ma_x$ to the car:

$$\sum F_x = F - mg\sin\theta - F_f = 0$$

Relate F to the power output of the engine and the speed of the car:

Since $P = Fv$, $F = \dfrac{P}{v}$

Substitute for F and solve for θ:

$$\theta = \sin^{-1}\left[\frac{\frac{P}{v} - F_{20}}{mg}\right]$$

Substitute numerical values and evaluate θ:

$$\theta = \sin^{-1}\left[\frac{\frac{40\,\text{kW}}{20\,\text{m/s}} - 491\,\text{N}}{(1000\,\text{kg})(9.81\,\text{m/s}^2)}\right] = \boxed{8.85°}$$

(d) Express the equivalence of the work done by the engine in driving the car at the two speeds:

$$W_{\text{engine}} = F_{20}(\Delta s)_{20} = F_{30}(\Delta s)_{30}$$

Let ΔV represent the volume of fuel consumed by the engine driving the car on a level road and divide both sides of the work equation by ΔV to obtain:

$$F_{20}\frac{(\Delta s)_{20}}{\Delta V} = F_{30}\frac{(\Delta s)_{30}}{\Delta V}$$

Solve for $\dfrac{(\Delta s)_{30}}{\Delta V}$:

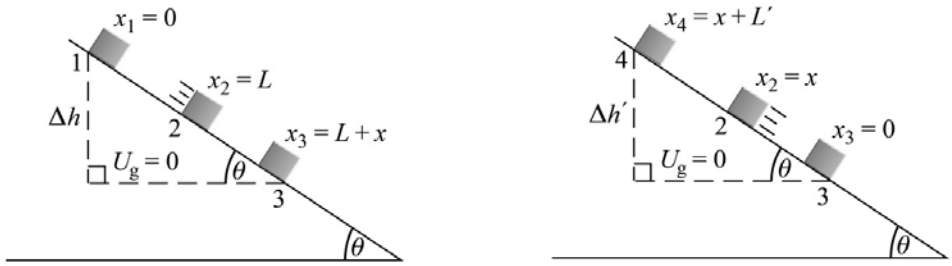
$$\frac{(\Delta s)_{30}}{\Delta V} = \frac{F_{20}}{F_{30}}\frac{(\Delta s)_{20}}{\Delta V}$$

Substitute numerical values and evaluate $\dfrac{(\Delta s)_{30}}{\Delta V}$:

$$\frac{(\Delta s)_{30}}{\Delta V} = \frac{491\,\text{N}}{981\,\text{N}}(12.7\,\text{km/L}) = \boxed{6.36\,\text{km/L}}$$

82 ••

Picture the Problem Let the system include the earth, block, spring, and incline. Then W_{ext} = 0. The pictorial representation to the left shows the block sliding down the incline and compressing the spring. Choose $U_g = 0$ at the elevation at which the spring is fully compressed. We can use the conservation of mechanical energy to determine the maximum compression of the spring. The pictorial representation to the right shows the block sliding up the rough incline after being accelerated by the fully compressed spring. We can use the work-energy theorem with friction to determine how far up the incline the block slides before stopping.



(*a*) Apply conservation of mechanical energy to the system as it evolves from state 1 to state 3:

$$\Delta K + \Delta U_g + \Delta U_s = 0$$

or

$$K_3 - K_1 + U_{g,3} - U_{g,1} + U_{s,3} - U_{s,1} = 0$$

Because $K_3 = K_1 = U_{g,3} = U_{s,1} = 0$:

$$-U_{g,1} + U_{s,3} = 0$$

or

$$-mg\Delta h + \tfrac{1}{2}kx^2 = 0$$

Relate Δh to $L + x$ and θ and substitute to obtain:

$$\Delta h = (L + x)\sin\theta$$

$$\therefore \tfrac{1}{2}kx^2 - mg(L + x)\sin\theta = 0$$

Rewrite this equation in the form of an explicit quadratic equation:

$$\tfrac{1}{2}kx^2 - (mg\sin\theta)x - mgL\sin\theta = 0$$

Substitute for *k*, *m*, *g*, θ and *L* to obtain:

$$\left(50\,\frac{\text{N}}{\text{m}}\right)x^2 - (9.81\,\text{N})x - 39.24\,\text{J} = 0$$

Solve for the physically meaningful (i.e., positive) root:

$$x = \boxed{0.989\,\text{m}}$$

(*b*) Proceed as in (*a*) but include energy dissipated by friction:

$$-U_{g,1} + U_{s,3} + \Delta E_{\text{therm}} = 0$$

The mechanical energy transformed to thermal energy is given by:

$$\Delta E_{\text{therm}} = F_f(L + x) = \mu_k F_n(L + x) = \mu_k mg\cos\theta(L + x)$$

Substitute for Δh and ΔE_{therm} to obtain:

$$-mg(L+x)\sin\theta + \tfrac{1}{2}kx^2 + \mu_k mg\cos\theta(L+x) = 0$$

Substitute for k, m, g, θ, μ_k and L to obtain:

$$\left(50\,\frac{\text{N}}{\text{m}}\right)x^2 - (6.41\,\text{N})x - 25.65\,\text{J} = 0$$

Solve for the positive root:

$$x = \boxed{0.783\,\text{m}}$$

(*c*) Apply the work-energy theorem with friction to the system as it evolves from state 3 to state 4:

$$K_4 - K_3 + U_{g,4} - U_{g,3} + U_{s,4} - U_{s,3} + \Delta E_{\text{therm}} = 0$$

Because $K_4 = K_1 = U_{g,3} = U_{s,4} = 0$:

$$U_{g,4} - U_{s,3} + \Delta E_{\text{therm}} = 0$$

or

$$-mg\Delta h' + \tfrac{1}{2}kx^2 + \Delta E_{\text{therm}} = 0$$

Substitute for $\Delta h'$ and ΔE_{therm} to obtain:

$$-mg(L'+x)\sin\theta + \tfrac{1}{2}kx^2 + \mu_k mg\cos\theta(L'+x) = 0$$

Solve for L' with $x = 0.783$ m:

$$L' = \boxed{1.54\,\text{m}}$$

83 ••

Picture the Problem The work done by the engines maintains the kinetic energy of the cars and overcomes the work done by frictional forces. Let the system include the earth, track, and the cars *but not the engines*. Then the engines will do external work on the system and we can use this work to find the power output of the train's engines.

(*a*) Use the definition of kinetic energy:

$$K = \tfrac{1}{2}mv^2 = \tfrac{1}{2}(2\times10^6\,\text{kg})\left(15\,\frac{\text{km}}{\text{h}}\cdot\frac{1\,\text{h}}{3600\,\text{s}}\right)^2 = \boxed{17.4\,\text{MJ}}$$

(*b*) The change in potential energy of the train is:

$$\Delta U = mg\Delta h = (2\times10^6\,\text{kg})(9.81\,\text{m/s}^2)(707\,\text{m}) = \boxed{1.39\times10^{10}\,\text{J}}$$

(*c*) Express the energy dissipated by kinetic friction:

$$\Delta E_{\text{therm}} = f\Delta s$$

Express the frictional force: $f = 0.008mg$

Substitute for f and evaluate ΔE_{therm}:

$$\Delta E_{\text{therm}} = 0.008mg\Delta s = 0.008\left(2\times10^{6}\text{ kg}\right)\left(9.81\text{m/s}^{2}\right)\left(62\text{ km}\right) = \boxed{9.73\times10^{9}\text{ J}}$$

(*d*) Express the power output of the train's engines in terms of the work done by them:

$$P = \frac{\Delta W}{\Delta t}$$

Use the work-energy theorem with friction to find the work done by the train's engines:

$$W_{\text{ext}} = \Delta K + \Delta U + \Delta E_{\text{therm}}$$

or, because $\Delta K = 0$,

$$W_{\text{ext}} = \Delta U + \Delta E_{\text{therm}}$$

Find the time during which the engines do this work:

$$\Delta t = \frac{\Delta s}{v}$$

Substitute in the expression for P to obtain:

$$P = \frac{\left(\Delta U + \Delta E_{\text{therm}}\right)v}{\Delta s}$$

Substitute numerical values and evaluate P:

$$P = \left(1.39\times10^{10}\text{ J} + 9.73\times10^{9}\text{ J}\right)\frac{\left(15\dfrac{\text{km}}{\text{h}}\cdot\dfrac{1\text{h}}{3600\text{s}}\right)}{62\text{ km}} = \boxed{1.59\text{MW}}$$

***84 ••**

Picture the Problem While on a horizontal surface, the work done by an automobile engine changes the kinetic energy of the car and does work against friction. These energy transformations are described by the work-energy theorem with friction. Let the system include the earth, the roadway, and the car *but not the car's engine*.

(*a*) The required energy equals the change in the kinetic energy of the car:

$$\Delta K = \tfrac{1}{2}mv^{2} = \tfrac{1}{2}\left(1200\text{ kg}\right)\left(50\frac{\text{km}}{\text{h}}\cdot\frac{1\text{h}}{3600\text{s}}\right)^{2} = \boxed{116\text{ kJ}}$$

(*b*) The required energy equals the

$$\Delta E_{\text{therm}} = f\Delta s$$

work done against friction:

Substitute numerical values and evaluate ΔE_{therm}:

$$\Delta E_{\text{therm}} = (300\,\text{N})(300\,\text{m}) = \boxed{90.0\,\text{kJ}}$$

(*c*) Apply the work-energy theorem with friction to express the required energy:

$$E' = W_{\text{ext}} = \Delta K + \Delta E_{\text{therm}} = \Delta K + 0.75E$$

Divide both sides of the equation by *E* to express the ratio of the two energies:

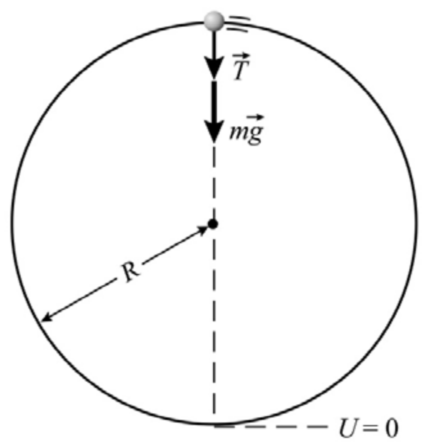
$$\frac{E'}{E} = \frac{\Delta K}{E} + 0.75$$

Substitute numerical values and evaluate E'/E:

$$\frac{E'}{E} = \frac{116\,\text{kJ}}{90\,\text{kJ}} + 0.75 = \boxed{2.04}$$

***85 •••**

Picture the Problem Assume that the bob is moving with speed *v* as it passes the top vertical point when looping around the peg. There are two forces acting on the bob: the tension in the string (if any) and the force of gravity, *Mg*; both point downward when the ball is in the topmost position. The minimum possible speed for the bob to pass the vertical occurs when the tension is 0; from this, gravity must supply the centripetal force required to keep the ball moving in a circle. We can use conservation of energy to relate *v* to *L* and *R*.



Express the condition that the bob swings around the peg in a full circle:

$$M\frac{v^2}{R} > Mg$$

Simplify to obtain:

$$\frac{v^2}{R} > g$$

Use conservation of energy to relate the kinetic energy of the bob at the bottom of the loop to its potential energy at the top of its swing:

$$\tfrac{1}{2}Mv^2 = Mg(L - 2R)$$

Solve for v^2:

$$v^2 = 2g(L - 2R)$$

Substitute to obtain:

$$\frac{2g(L - 2R)}{R} > g$$

Solve for R:

$$R < \boxed{\frac{2}{5}L}$$

86 ••

Picture the Problem If the wood exerts an average force F on the bullet, the work it does has magnitude FD. This must be equal to the change in the kinetic energy of the bullet, or because the final kinetic energy of the bullet is zero, to the negative of the initial kinetic energy. We'll let m be the mass of the bullet and v its initial speed and apply the work-kinetic energy theorem to relate the penetration depth to v.

Apply the work-kinetic energy theorem to relate the penetration depth to the change in the kinetic energy of the bullet:

$$W_{total} = \Delta K = K_f - K_i$$

or, because $K_f = 0$,

$$W_{total} = -K_i$$

Substitute for W_{total} and K_i to obtain:

$$FD = -\tfrac{1}{2}mv^2$$

Solve for D to obtain:

$$D = -\frac{mv^2}{2F}$$

For an identical bullet with twice the speed we have:

$$FD' = -\tfrac{1}{2}m(2v)^2$$

Solve for D' to obtain:

$$D' = 4\left(-\frac{mv^2}{2F}\right) = 4D$$

and $\boxed{(c)\text{ is correct.}}$

87 ••

Picture the Problem For part (a), we'll let the system include the glider, track, weight, and the earth. The speeds of the glider and the falling weight will be the same while they are in motion. Let their common speed when they have moved a distance Y be v and let the zero of potential energy be at the elevation of the weight when it has fallen the distance Y. We can use conservation of energy to relate the speed of the glider (and the weight) to the distance the weight has fallen. In part (b), we'll let the direction of motion be the x direction, the tension in the connecting string be T, and apply Newton's 2^{nd} law to the glider and the weight to find their common acceleration. Because this acceleration is constant, we can use a constant-acceleration equation to find their common speed when they have moved a distance Y.

(a) Use conservation of energy to relate the kinetic and potential energies of the system:

$$\Delta K + \Delta U = 0$$

or

$$K_f - K_i + U_f - U_i = 0$$

Because the system starts from rest and $U_f = 0$:

$$K_f - U_i = 0$$

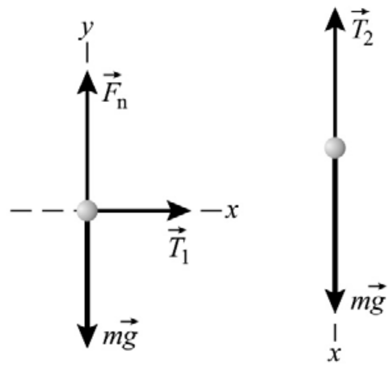
Substitute to obtain:

$$\tfrac{1}{2}mv^2 + \tfrac{1}{2}Mv^2 - mgY = 0$$

Solve for v:

$$v = \boxed{\sqrt{\frac{2mgY}{M+m}}}$$

(b) The free-body diagrams for the glider and the weight are shown to the right:



Apply Newton's 3rd law to obtain:

$$\left|\vec{\boldsymbol{T}}_1\right| = \left|\vec{\boldsymbol{T}}_2\right| = T$$

Apply $\sum F_x = ma$ to the glider:

$$T = Ma$$

Apply $\sum F_x = ma$ to the weight:

$$mg - T = ma$$

Add these equations to eliminate T and obtain:

$$mg = Ma + ma$$

Solve for a to obtain:

$$a = g\frac{m}{m+M}$$

Using a constant-acceleration equation, relate the speed of the glider to its initial speed and to the distance that the weight has fallen:

$$v^2 = v_0^2 + 2aY$$

or, because $v_0 = 0$,

$$v^2 = 2aY$$

Substitute for a and solve for v to obtain:

$$v = \boxed{\sqrt{\frac{2mgY}{M+m}}}$$, the same result we obtained in part (a).

***88 ••**

Picture the Problem We're given $P = dW/dt$ and are asked to evaluate it under the assumed conditions.

Express the rate of energy expenditure by the man:

$$P = 3mv^2 = 3(10\,\text{kg})(3\,\text{m/s})^2 = 270\,\text{W}$$

Express the rate of energy expenditure P' assuming that his

$$P = \tfrac{1}{5}P'$$

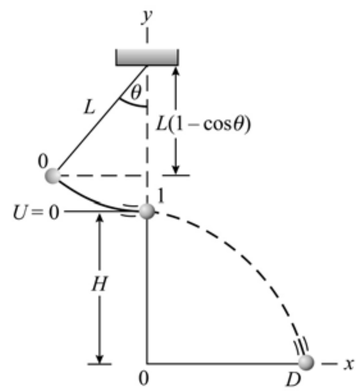
muscles have an efficiency of 20%:

Solve for and evaluate P':

$$P' = 5P = 5(270\,\text{W}) = \boxed{1.35\,\text{kW}}$$

89 ••

Picture the Problem The pictorial representation shows the bob swinging through an angle θ before the thread is cut and it is launched horizontally. Let its speed at position 1 be v. We can use conservation of energy to relate v to the change in the potential energy of the bob as it swings through the angle θ. We can find its flight time Δt from a constant-acceleration equation and then express D as the product of v and Δt.



Relate the distance D traveled horizontally by the bob to its launch speed v and time of flight Δt:

$$D = v\Delta t \qquad (1)$$

Use conservation of energy to relate its launch speed v to the length of the pendulum L and the angle θ:

$$K_1 - K_0 + U_1 - U_0 = 0$$

or, because $U_1 = K_0 = 0$,

$$K_1 - U_0 = 0$$

Substitute to obtain:

$$\tfrac{1}{2}mv^2 - mgL(1-\cos\theta) = 0$$

Solving for v yields:

$$v = \sqrt{2gL(1-\cos\theta)}$$

In the absence of air resistance, the horizontal and vertical motions of the bob are independent of each other and we can use a constant-acceleration equation to express the time of flight (the time to fall a distance H):

$$\Delta y = v_{0y}\Delta t + \tfrac{1}{2}a_y(\Delta t)^2$$

or, because $\Delta y = -H$, $a_y = -g$, and $v_{0y} = 0$,

$$-H = -\tfrac{1}{2}g(\Delta t)^2$$

Solve for Δt to obtain:

$$\Delta t = \sqrt{2H/g}$$

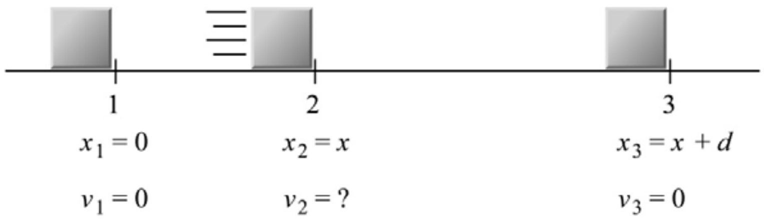
Substitute in equation (1) and simplify to obtain:

$$D = \sqrt{2gL(1-\cos\theta)}\sqrt{\frac{2H}{g}} = \boxed{2\sqrt{HL(1-\cos\theta)}}$$

which shows that, while D depends on θ, it is independent of g.

90 ••

Picture the Problem The pictorial representation depicts the block in its initial position against the compressed spring (1), as it separates from the spring with its maximum kinetic energy (2), and when it has come to rest after moving a distance $x + d$. Let the system consist of the earth, the block, and the surface on which the block slides. With this choice, $W_{ext} = 0$. We can use the work-energy theorem with friction to determine how far the block will slide before coming to rest.



(*a*) The work done by the spring on the block is given by:

$$W_{spring} = \Delta U_{spring} = \tfrac{1}{2}kx^2$$

Substitute numerical values and evaluate W_{spring}:

$$W_{spring} = \tfrac{1}{2}(20\ \text{N/cm})(3\ \text{cm})^2 = \boxed{0.900\ \text{J}}$$

(*b*) The energy dissipated by friction is given by:

$$\Delta E_{therm} = f\Delta s = \mu_k F_n \Delta x = \mu_k mg\Delta x$$

Substitute numerical values and evaluate ΔE_{therm}:

$$\Delta E_{therm} = (0.2)(5\ \text{kg})(9.81\ \text{m/s}^2)(0.03\ \text{m}) = \boxed{0.294\ \text{J}}$$

(*c*) Apply the conservation of energy between points 1 and 2:

$$K_2 - K_1 + U_{s,2} - U_{s,1} + \Delta E_{therm} = 0$$

Because $K_1 = U_{s,2} = 0$:

$$K_2 - U_{s,1} + \Delta E_{therm} = 0$$

Substitute to obtain:

$$\tfrac{1}{2}mv_2^2 - \tfrac{1}{2}kx^2 + \Delta E_{therm} = 0$$

Solve for v_2:

$$v_2 = \sqrt{\frac{kx^2 - 2\Delta E_{therm}}{m}}$$

Substitute numerical values and evaluate v_2:

$$v_2 = \sqrt{\frac{(20\ \text{N/cm})(3\ \text{cm})^2 - 2(0.294\ \text{J})}{5\ \text{kg}}} = \boxed{0.492\ \text{m/s}}$$

(*d*) Apply the conservation of energy between points 1 and 3:

$$\Delta K + U_{s,3} - U_{s,1} + \Delta E_{therm} = 0$$

Because $\Delta K = U_{s,3} = 0$:

$$-U_{s,1} + \Delta E_{therm} = 0$$

or

$$-\tfrac{1}{2}kx^2 + \mu_k mg(x+d) = 0$$

Solve for *d*:

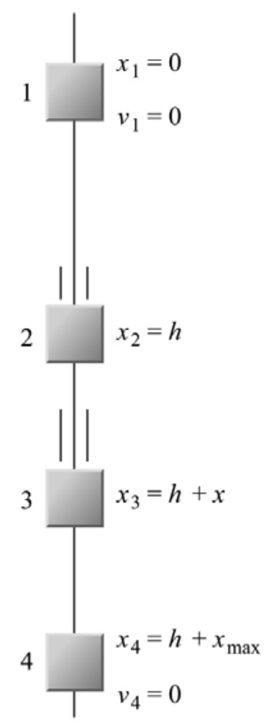
$$d = \frac{kx^2}{2\mu_k mg} - x$$

Substitute numerical values and evaluate *d*:

$$d = \frac{(20\,\text{N/cm})(3\,\text{cm})^2}{2(0.2)(5\,\text{kg})(9.81\,\text{m/s}^2)} - 0.03\,\text{m} = \boxed{6.17\,\text{cm}}$$

91 ••

Picture the Problem The pictorial representation shows the block initially at rest at point 1, falling under the influence of gravity to point 2, partially compressing the spring as it continues to gain kinetic energy at point 3, and finally coming to rest at point 4 with the spring fully compressed. Let the system consist of the earth, the block, and the spring so that $W_{ext} = 0$. Let $U_g = 0$ at point 3 for part (*a*) and at point 4 for part (*b*). We can use the work-energy theorem to express the kinetic energy of the system as a function of the block's position and then use this function to maximize *K* as well as determine the maximum compression of the spring and the location of the block when the system has half its maximum kinetic energy.



(*a*) Apply conservation of mechanical energy to describe the energy transformations between state 1 and state 3:

$$\Delta K + \Delta U_g + \Delta U_s = 0$$

or

$$K_3 - K_1 + U_{g,3} - U_{g,1} + U_{s,3} - U_{s,1} = 0$$

Because $K_1 = U_{g,3} = U_{s,1} = 0$:

$$K_3 - U_{g,1} + U_{s,3} = 0$$

and
$$K_3 = K = mg(h+x) - \tfrac{1}{2}kx^2$$

Differentiate K with respect to x and set this derivative equal to zero to identify extreme values:

$$\frac{dK}{dx} = mg - kx = 0 \text{ for extreme values.}$$

Solve for x:

$$x = \frac{mg}{k}$$

Evaluate the second derivative of K with respect to x:

$$\frac{d^2K}{dt^2} = -k < 0$$
$$\Rightarrow x = \frac{mg}{k} \text{ maximizes } K.$$

Evaluate K for $x = mg/k$:

$$K_{\max} = mgh + mg\left(\frac{mg}{k}\right) - \tfrac{1}{2}k\left(\frac{mg}{k}\right)^2$$
$$= \boxed{mgh + \frac{m^2g^2}{2k}}$$

(b) The spring will have its maximum compression at point 4 where $K = 0$:

$$mg(h + x_{\max}) - \tfrac{1}{2}kx_{\max}^2 = 0$$
or
$$x_{\max}^2 - \frac{2mg}{k}x_{\max} - \frac{2mgh}{k} = 0$$

Solve for x and keep the physically meaningful root:

$$x_{\max} = \boxed{\frac{mg}{k} + \sqrt{\frac{m^2g^2}{k^2} + \frac{2mgh}{k}}}$$

(c) Apply conservation of mechanical energy to the system as it evolves from state 1 to the state in which $K = \tfrac{1}{2}K_{\max}$:

$$\Delta K + \Delta U_{\text{g}} + \Delta U_{\text{s}} = 0$$
or
$$K - K_1 + U_{\text{g},3} - U_{\text{g},1} + U_{\text{s},3} - U_{\text{s},1} = 0$$

Because $K_1 = U_{\text{g},3} = U_{\text{s},1} = 0$:

$$K - U_{\text{g},1} + U_{\text{s},3} = 0$$
and
$$K = mg(h+x) - \tfrac{1}{2}kx^2$$

Substitute for K to obtain:

$$\tfrac{1}{2}\left(mgh+\frac{m^2g^2}{2k}\right)=mg(h+x)-\tfrac{1}{2}kx^2$$

Express this equation in quadratic form:

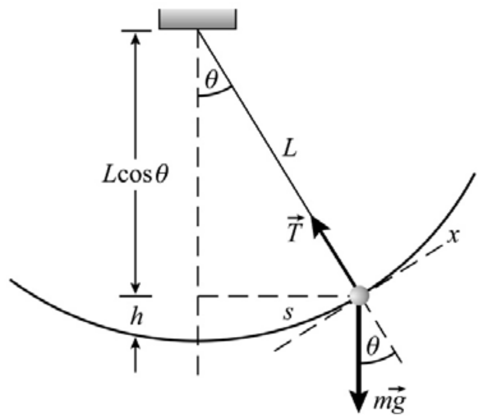
$$x^2-\frac{2mg}{k}x+\left(\frac{m^2g^2}{2k^2}-\frac{mgh}{k}\right)=0$$

Solve for the positive value of x:

$$\boxed{x=\frac{mg}{k}+\sqrt{\frac{2m^2g^2}{k^2}+\frac{4mgh}{k}}}$$

92 •••

Picture the Problem The free-body diagram shows the forces acting on the pendulum bob. The application of Newton's 2nd law leads directly to the required expression for the tangential acceleration. Recall that, provided θ is in radian measure, $s = L\theta$. Differentiation with respect to time produces the result called for in part (*b*). The remaining parts of the problem simply require following the directions for each part.



(*a*) Apply $\sum F_x = ma_x$ to the bob:

$$F_{\tan}=-mg\sin\theta=ma_{\tan}$$

Solve for $a_{\tan}$:

$$\boxed{a_{\tan}=dv/dt=-g\sin\theta}$$

(*b*) Relate the arc distance s to the length of the pendulum L and the angle θ:

$$s=L\theta$$

Differentiate with respect to time:

$$ds/dt=\boxed{v=Ld\theta/dt}$$

(*c*) Multiply $\frac{dv}{dt}$ by $\frac{d\theta}{d\theta}$ and substitute for $\frac{d\theta}{dt}$ from part (*b*):

$$\frac{dv}{dt}=\frac{dv}{dt}\frac{d\theta}{d\theta}=\frac{dv}{d\theta}\frac{d\theta}{dt}$$

$$=\boxed{\frac{dv}{d\theta}\left(\frac{v}{L}\right)}$$

(*d*) Equate the expressions for *dv*/*dt* from (*a*) and (*c*):

$$\frac{dv}{d\theta}\left(\frac{v}{L}\right) = -g\sin\theta$$

Separate the variables to obtain:

$$\boxed{vdv = -gL\sin\theta\, d\theta}$$

(*e*) Integrate the left side of the equation in part (*d*) from $v = 0$ to the final speed v and the right side from $\theta = \theta_0$ to $\theta = 0$:

$$\int_0^v v'dv' = \int_{\theta_0}^0 -gL\sin\theta' d\theta'$$

Evaluate the limits of integration to obtain:

$$\tfrac{1}{2}v^2 = gL(1-\cos\theta_0)$$

Note, from the figure, that $h = L(1 - \cos\theta_0)$. Substitute and solve for v:

$$v = \boxed{\sqrt{2gh}}$$

93 •••

Picture the Problem The potential energy of the climber is the sum of his gravitational potential energy and the potential energy stored in the spring-like bungee cord. Let θ be the angle which the position of the rock climber on the cliff face makes with a vertical axis and choose the zero of gravitational potential energy to be at the bottom of the cliff. We can use the definitions of U_g and U_{spring} to express the climber's total potential energy.

(*a*) Express the total potential energy of the climber:

$$U(s) = U_{\text{bungee cord}} + U_g$$

Substitute to obtain:

$$\begin{aligned} U(s) &= \tfrac{1}{2}k(s-L)^2 + Mgy \\ &= \tfrac{1}{2}k(s-L)^2 + MgH\cos\theta \\ &= \tfrac{1}{2}k(s-L)^2 + MgH\cos\left(\frac{s}{H}\right) \end{aligned}$$

A spreadsheet solution is shown below. The constants used in the potential energy function and the formulas used to calculate the potential energy are as follows:

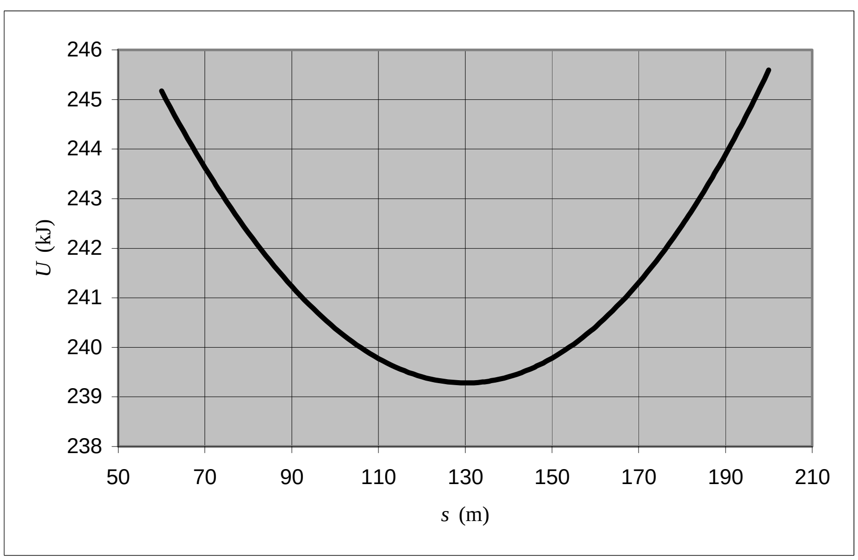
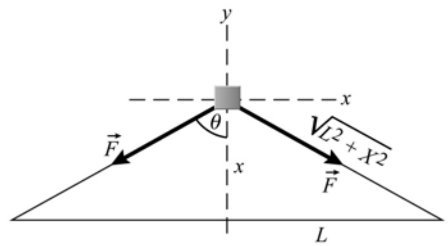
151				200	2.46E+05

The following graph was plotted using the data from columns D (s) and E ($U(s)$).



***94 •••**

Picture the Problem The diagram shows the forces each of the springs exerts on the block. The change in the potential energy stored in the springs is due to the elongation of both springs when the block is displaced a distance x from its equilibrium position and we can find ΔU using $\frac{1}{2}k(\Delta L)^2$. We can find the magnitude of the force pulling the block back toward its equilibrium position by finding the sum of the magnitudes of the y components of the forces exerted by the springs. In Part (d) we can use conservation of energy to find the speed of the block as it passes through its equilibrium position.



(a) Express the change in the potential energy stored in the springs when the block is displaced a distance x:

$$\Delta U = 2\left[\tfrac{1}{2}k(\Delta L)^2\right] = k(\Delta L)^2$$

where ΔL is the change in length of a spring.

Referring to the force diagram, express ΔL:

$$\Delta L = \sqrt{L^2 + x^2} - L$$

Substitute to obtain:

$$\Delta U = \boxed{k\left(\sqrt{L^2 + x^2} - L\right)^2}$$

(b) Sum the forces acting on the block to express $F_{\text{restoring}}$:

$$F_{\text{restoring}} = 2F\cos\theta = 2k\Delta L\cos\theta$$

$$= 2k\Delta L\frac{x}{\sqrt{L^2 + x^2}}$$

Substitute for ΔL to obtain:

$$F_{\text{restoring}} = 2k\left(\sqrt{L^2 + x^2} - L\right)\frac{x}{\sqrt{L^2 + x^2}}$$

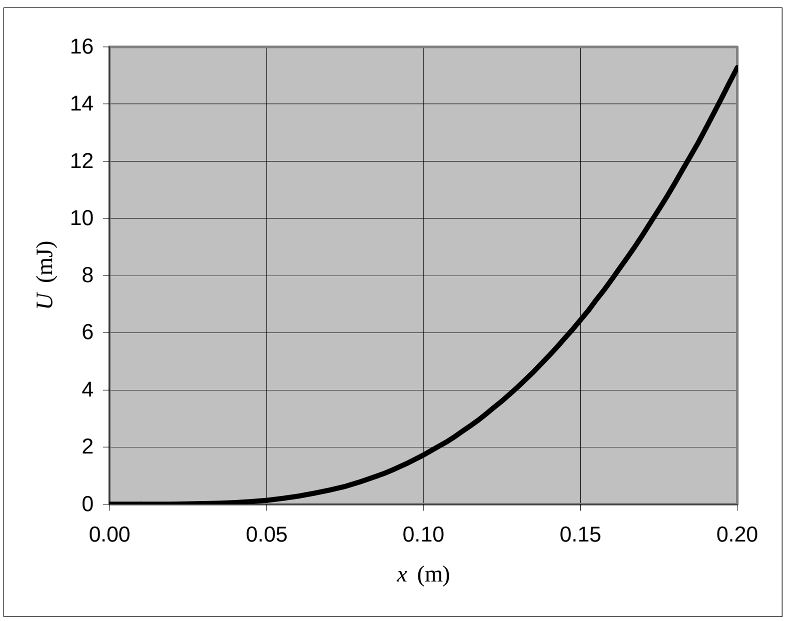
$$= \boxed{2kx\left(1 - \frac{L}{\sqrt{L^2 + x^2}}\right)}$$

(c) A spreadsheet program to calculate $U(x)$ is shown below. The constants used in the potential energy function and the formulas used to calculate the potential energy are as follows:

Cell	Content/Formula	Algebraic Form
B1	1	L
B2	1	k
B3	1	M
C8	C7+0.01	x
D7	$B$2*((C7^2+$B$1^2)^0.5–$B$1)^2	$U(x)$

	A	B	C	D
1	L =	0.1	m	
2	k =	1	N/m	
3	M =	1	kg	
4				
5				
6			*x*	*U*(*x*)
7			0	0
8			0.01	2.49E–07
9			0.02	3.92E–06
10			0.03	1.94E–05
11			0.04	5.93E–05
12			0.05	1.39E–04
23			0.16	7.86E–03
24			0.17	9.45E–03
25			0.18	1.12E–02
26			0.19	1.32E–02
27			0.20	1.53E–02

The following graph was plotted using the data from columns C (*x*) and D (*U*(*x*)).



(*d*) Use conservation of energy to relate the kinetic energy of the block as it passes through the equilibrium position to the change in its potential energy as it returns to its equilibrium position:

$$K_{\text{equilibrium}} = \Delta U$$

or

$$\tfrac{1}{2}Mv^2 = \Delta U$$

Solve for *v* to obtain:

$$v=\sqrt{\frac{2\Delta U}{M}}=\sqrt{\frac{2k\left(\sqrt{L^2+x^2}-L\right)^2}{M}}$$
$$=\left(\sqrt{L^2+x^2}-L\right)\sqrt{\frac{2k}{M}}$$

Substitute numerical values and evaluate *v*:

$$v=\left(\sqrt{(0.1\,\text{m})^2+(0.1\,\text{m})^2}-0.1\,\text{m}\right)\sqrt{\frac{2(1\,\text{N/m})}{1\,\text{kg}}}=\boxed{5.86\,\text{cm/s}}$$

Chapter 8
Systems of Particles and Conservation of Momentum

Conceptual Problems

1 •

Determine the Concept A doughnut. The definition of the center of mass of an object does not require that there be any matter at its location. Any hollow sphere (such as a basketball) or an empty container with any geometry are additional examples of three-dimensional objects that have no mass at their center of mass.

***2** •

Determine the Concept The center of mass is midway between the two balls and is in free-fall along with them (all forces can be thought to be concentrated at the center of mass.) The center of mass will initially rise, then fall.

Because the initial velocity of the center of mass is half of the initial velocity of the ball thrown upwards, the mass thrown upwards will rise for twice the time that the center of mass rises. Also, the center of mass will rise until the velocities of the two balls are equal but opposite. $\boxed{(b)\text{ is correct.}}$

3 •

Determine the Concept The acceleration of the center of mass of a system of particles is described by $\vec{F}_{\text{net,ext}} = \sum_{\text{i}} \vec{F}_{\text{i,ext}} = M\vec{a}_{\text{cm}}$, where M is the total mass of the system.

Express the acceleration of the center of mass of the two pucks:

$$a_{\text{cm}} = \frac{F_{\text{net,ext}}}{M} = \frac{F_1}{m_1 + m_2}$$

and $\boxed{(b)\text{ is correct.}}$

4 •

Determine the Concept The acceleration of the center of mass of a system of particles is described by $\vec{F}_{\text{net,ext}} = \sum_{\text{i}} \vec{F}_{\text{i,ext}} = M\vec{a}_{\text{cm}}$, where M is the total mass of the system.

Express the acceleration of the center of mass of the two pucks:

$$a_{\text{cm}} = \frac{F_{\text{net,ext}}}{M} = \frac{F_1}{m_1 + m_2}$$

because the spring force is an internal force.

$\boxed{(b)\text{ is correct.}}$

***5** •

Determine the Concept No. Consider a 1-kg block with a speed of 1 m/s and a 2- kg block with a speed of 0.707 m/s. The blocks have equal kinetic energies but momenta of magnitude 1 kg·m /s and 1.414 kg·m/s, respectively.

6 •

(*a*) True. The momentum of an object is the product of its mass and velocity. Therefore, if we are considering just the magnitudes of the momenta, the momentum of a heavy object is greater than that of a light object moving at the same speed.

(*b*) True. Consider the collision of two objects of equal mass traveling in opposite directions with the same speed. Assume that they collide inelastically. The mechanical energy of the system is not conserved (it is transformed into other forms of energy), but the momentum of the system is the same after the collision as before the collision, i.e., zero. Therefore, for any inelastic collision, the momentum of a system may be conserved even when mechanical energy is not.

(*c*) True. This is a restatement of the expression for the total momentum of a system of particles.

7 •

Determine the Concept To the extent that the system in which the rifle is being fired is an isolated system, i.e., the net external force is zero, momentum is conserved during its firing.

Apply conservation of momentum to the firing of the rifle:

$$\vec{p}_{\text{rifle}} + \vec{p}_{\text{bullet}} = 0$$

or

$$\boxed{\vec{p}_{\text{rifle}} = -\vec{p}_{\text{bullet}}}$$

***8** •

Determine the Concept When she jumps from a boat to a dock, she must, in order for momentum to be conserved, give the boat a recoil momentum, i.e., her forward momentum must be the same as the boat's backward momentum. The energy she imparts to the boat is $E_{\text{boat}} = p_{\text{boat}}^2 / 2m_{\text{boat}}$.

When she jumps from one dock to another, the mass of the dock plus the earth is so large that the energy she imparts to them is essentially zero.

***9** ••

Determine the Concept Conservation of momentum requires only that the net external force acting on the system be zero. It does not require the presence of a medium such as air.

10 •

Determine the Concept The kinetic energy of the sliding ball is $\frac{1}{2}mv_{\text{cm}}^2$. The kinetic energy of the rolling ball is $\frac{1}{2}mv_{\text{cm}}^2 + K_{\text{rel}}$, where its kinetic energy relative to its center of mass is K_{rel}. Because the bowling balls are identical and have the same velocity, the rolling ball has more energy.

11 •

Determine the Concept Think of someone pushing a box across a floor. Her push on the box is equal but opposite to the push of the box on her, but the action and reaction forces act on *different objects*. You can only add forces when they act on the same object.

12 •

Determine the Concept It's not possible for both to remain at rest after the collision, as that wouldn't satisfy the requirement that momentum is conserved. It is possible for one to remain at rest: This is what happens for a one-dimensional collision of two identical particles colliding elastically.

13 •

Determine the Concept It violates the conservation of momentum! To move forward requires pushing something backwards, which Superman doesn't appear to be doing when flying around. In a similar manner, if Superman picks up a train and throws it at Lex Luthor, he (Superman) ought to be tossed backwards at a pretty high speed to satisfy the conservation of momentum.

***14** ••

Determine the Concept There is only one force which can cause the car to move forward–the friction of the road! The car's engine causes the tires to rotate, but if the road were frictionless (as is closely approximated by icy conditions) the wheels would simply spin without the car moving anywhere. Because of friction, the car's tire pushes backwards against the road–from Newton's third law, the frictional force acting on the tire must then push it forward. This may seem odd, as we tend to think of friction as being a retarding force only, but true.

15 ••

Determine the Concept The friction of the tire against the road causes the car to slow down. This is rather subtle, as the tire is in contact with the ground without slipping at all times, and so as you push on the brakes harder, the force of static friction of the road against the tires must increase. Also, of course, the brakes heat up, and not the tires.

16 •

Determine the Concept Because $\Delta p = F\Delta t$ is constant, a safety net reduces the force acting on the performer by increasing the time Δt during which the slowing force acts.

17 •

Determine the Concept Assume that the ball travels at 80 mi/h ≈ 36 m/s. The ball stops in a distance of about 1 cm. So the distance traveled is about 2 cm at an average speed of about 18 m/s. The collision time is $\frac{0.02\,\text{m}}{18\,\text{m/s}} \approx 1\,\text{ms}$.

18 •

Determine the Concept The average force on the glass is less when falling on a carpet because Δt is longer.

19 •

(*a*) False. In a perfectly inelastic collision, the colliding bodies stick together but may or may not continue moving, depending on the momentum each brings to the collision.

(*b*) True. In a head-on elastic collision both kinetic energy and momentum are conserved and the relative speeds of approach and recession are equal.

(*c*) True. This is the definition of an elastic collision.

***20** ••

Determine the Concept All the initial kinetic energy of the isolated system is lost in a perfectly inelastic collision in which the velocity of the center of mass is zero.

21 ••

Determine the Concept We can find the loss of kinetic energy in these two collisions by finding the initial and final kinetic energies. We'll use conservation of momentum to find the final velocities of the two masses in each perfectly elastic collision.

(*a*) Letting *V* represent the velocity of the masses after their perfectly inelastic collision, use conservation of momentum to determine *V*:

$$p_{\text{before}} = p_{\text{after}}$$

or

$$mv - mv = 2mV \Rightarrow V = 0$$

Express the loss of kinetic energy for the case in which the two objects have oppositely directed velocities of magnitude *v*/2:

$$\Delta K = K_\text{f} - K_\text{i} = 0 - 2\left(\tfrac{1}{2}m\left(\frac{v}{2}\right)^2\right)$$

$$= -\frac{mv^2}{4}$$

Letting *V* represent the velocity of the masses after their perfectly inelastic collision, use conservation of momentum to determine *V*:

$$p_{\text{before}} = p_{\text{after}}$$

or

$$mv = 2mV \Rightarrow V = \tfrac{1}{2}v$$

Express the loss of kinetic energy for the case in which the one object is initially at rest and the other has an initial velocity *v*:

$$\Delta K = K_f - K_i = \tfrac{1}{2}(2m)\left(\frac{v}{2}\right)^2 - \tfrac{1}{2}mv^2 = -\frac{mv^2}{4}$$

The loss of kinetic energy is the same in both cases.

(*b*) Express the percentage loss for the case in which the two objects have oppositely directed velocities of magnitude *v*/2:

$$\frac{\Delta K}{K_{\text{before}}} = \frac{\frac{1}{4}mv^2}{\frac{1}{4}mv^2} = 100\%$$

Express the percentage loss for the case in which the one object is initially at rest and the other has an initial velocity *v*:

$$\frac{\Delta K}{K_{\text{before}}} = \frac{\frac{1}{4}mv^2}{\frac{1}{2}mv^2} = 50\%$$

The percentage loss is greatest for the case in which the two objects have oppositely directed velocities of magnitude *v*/2.

***22 ••**

Determine the Concept A will travel farther. Both peas are acted on by the same force, but pea A is acted on by that force for a longer time. By the impulse-momentum theorem, its momentum (and, hence, speed) will be higher than pea B's speed on leaving the shooter.

23 ••

Determine the Concept Refer to the particles as particle 1 and particle 2. Let the direction particle 1 is moving before the collision be the positive *x* direction. We'll use both conservation of momentum and conservation of mechanical energy to obtain an expression for the velocity of particle 2 after the collision. Finally, we'll examine the ratio of the final kinetic energy of particle 2 to that of particle 1 to determine the condition under which there is maximum energy transfer from particle 1 to particle 2.

Use conservation of momentum to obtain one relation for the final velocities:

$$m_1 v_{1,i} = m_1 v_{1,f} + m_2 v_{2,f} \qquad (1)$$

Use conservation of mechanical energy to set the velocity of

$$v_{2,f} - v_{1,f} = -(v_{2,i} - v_{1,i}) = v_{1,i} \qquad (2)$$

recession equal to the negative of the velocity of approach:

To eliminate $v_{1,f}$, solve equation (2) for $v_{1,f}$, and substitute the result in equation (1):

$$v_{1,f} = v_{2,f} + v_{1,i}$$
$$m_1 v_{1,i} = m_1\left(v_{2,f} - v_{1,i}\right) + m_2 v_{2,f}$$

Solve for $v_{2,f}$:

$$v_{2,f} = \frac{2m_1}{m_1 + m_2} v_{1,i}$$

Express the ratio R of $K_{2,f}$ to $K_{1,i}$ in terms of m_1 and m_2:

$$R = \frac{K_{2,f}}{K_{1,i}} = \frac{\frac{1}{2} m_2 \left(\frac{2m_1}{m_1 + m_2}\right)^2 v_{1,i}^2}{\frac{1}{2} m_1 v_{1,i}^2}$$
$$= \frac{m_2}{m_1} \frac{4m_1^2}{\left(m_1 + m_2\right)^2}$$

Differentiate this ratio with respect to m_2, set the derivative equal to zero, and obtain the quadratic equation:

$$-\frac{m_2^2}{m_1^2} + 1 = 0$$

Solve this equation for m_2 to determine its value for maximum energy transfer:

$$m_2 = m_1$$

(b) is correct because all of 1's kinetic energy is transferred to 2 when $m_2 = m_1$.

24 •

Determine the Concept In the center-of-mass reference frame the two objects approach with equal but opposite momenta and remain at rest after the collision.

25 •

Determine the Concept The water is changing direction when it rounds the corner in the nozzle. Therefore, the nozzle must exert a force on the stream of water to change its direction, and, from Newton's 3rd law, the water exerts an equal but opposite force on the nozzle.

26 •

Determine the Concept The collision usually takes place in such a short period of time that the impulse delivered by gravity or friction is negligible.

27 •

Determine the Concept No. $\vec{F}_{\text{ext,net}} = d\vec{p}/dt$ defines the relationship between the net force acting on a system and the rate at which its momentum changes. The net external force acting on the pendulum bob is the sum of the force of gravity and the tension in the string and these forces do not add to zero.

***28** ••

Determine the Concept We can apply conservation of momentum and Newton's laws of motion to the analysis of these questions.

(*a*) Yes, the car should slow down. An easy way of seeing this is to imagine a "packet" of grain being dumped into the car all at once: This is a completely inelastic collision, with the packet having an initial horizontal velocity of 0. After the collision, it is moving with the same horizontal velocity that the car does, so the car must slow down.

(*b*) When the packet of grain lands in the car, it initially has a horizontal velocity of 0, so it must be accelerated to come to the same speed as the car of the train. Therefore, the train must exert a force on it to accelerate it. By Newton's 3rd law, the grain exerts an equal but opposite force on the car, slowing it down. In general, this is a frictional force which causes the grain to come to the same speed as the car.

(*c*) No it doesn't speed up. Imagine a packet of grain being "dumped" out of the railroad car. This can be treated as a collision, too. It has the same horizontal speed as the railroad car when it leaks out, so the train car doesn't have to speed up or slow down to conserve momentum.

***29** ••

Determine the Concept Think of the stream of air molecules hitting the sail. Imagine that they bounce off the sail elastically–their net change in momentum is then roughly twice the change in momentum that they experienced going through the fan. Another way of looking at it: Initially, the air is at rest, but after passing through the fan and bouncing off the sail, it is moving backward–therefore, the boat must exert a net force on the air pushing it backward, and there must be a force on the boat pushing it forward.

Estimation and Approximation

30 ••

Picture the Problem We can estimate the time of collision from the average speed of the car and the distance traveled by the center of the car during the collision. We'll assume a car length of 6 m. We can calculate the average force exerted by the wall on the car from the car's change in momentum and it's stopping time.

(*a*) Relate the stopping time to the assumption that the center of the car travels halfway to the wall with constant deceleration:

$$\Delta t = \frac{d_{\text{stopping}}}{v_{\text{av}}} = \frac{\frac{1}{2}\left(\frac{1}{2}L_{\text{car}}\right)}{v_{\text{av}}} = \frac{\frac{1}{4}L_{\text{car}}}{v_{\text{av}}}$$

Express and evaluate v_{av}:

$$v_{av}=\frac{v_i+v_f}{2}=\frac{0+90\frac{\text{km}}{\text{h}}\times\frac{1\,\text{h}}{3600\,\text{s}}\times\frac{1000\,\text{m}}{\text{km}}}{2}=12.5\,\text{m/s}$$

Substitute for v_{av} and evaluate Δt:

$$\Delta t=\frac{\frac{1}{4}(6\,\text{m})}{12.5\,\text{m/s}}=\boxed{0.120\,\text{s}}$$

(b) Relate the average force exerted by the wall on the car to the car's change in momentum:

$$F_{av}=\frac{\Delta p}{\Delta t}=\frac{(2000\,\text{kg})\left(90\frac{\text{km}}{\text{h}}\times\frac{1\,\text{h}}{3600\,\text{s}}\times\frac{1000\,\text{m}}{\text{km}}\right)}{0.120\,\text{s}}=\boxed{417\,\text{kN}}$$

31 ••

Picture the Problem Let the direction the railcar is moving be the positive *x* direction and the system include the earth, the pumpers, and the railcar. We'll also denote the railcar with the letter c and the pumpers with the letter p. We'll use conservation of momentum to relate the center of mass frame velocities of the car and the pumpers and then transform to the earth frame of reference to find the time of fall of the car.

(a) Relate the time of fall of the railcar to the distance it falls and its velocity as it leaves the bank:

$$\Delta t=\frac{\Delta y}{v_c}$$

Use conservation of momentum to find the speed of the car relative to the velocity of its center of mass:

$$\vec{p}_i=\vec{p}_f$$

or

$$m_c u_c+m_p u_p=0$$

Relate u_c to u_p and solve for u_c:

$$u_c-u_p=4\,\text{m/s}$$

$$\therefore u_p=u_c-4\,\text{m/s}$$

Substitute for u_p to obtain:

$$m_c u_c+m_p(u_c-4\,\text{m/s})=0$$

Solve for and evaluate u_c:

$$u_c = \frac{4\,\text{m/s}}{1+\dfrac{m_c}{m_p}} = \frac{4\,\text{m/s}}{1+\dfrac{350\,\text{kg}}{4(75\,\text{kg})}} = 1.85\,\text{m/s}$$

Relate the speed of the car to its speed relative to the center of mass of the system:

$$v_c = u_c + v_{cm} = 1.85\frac{\text{m}}{\text{s}} + 32\frac{\text{km}}{\text{h}}\times\frac{1\,\text{h}}{3600\,\text{s}}\times\frac{1000\,\text{m}}{\text{km}} = 10.74\,\text{m/s}$$

Substitute and evaluate Δt:

$$\Delta t = \frac{25\,\text{m}}{10.74\,\text{m/s}} = \boxed{2.33\,\text{s}}$$

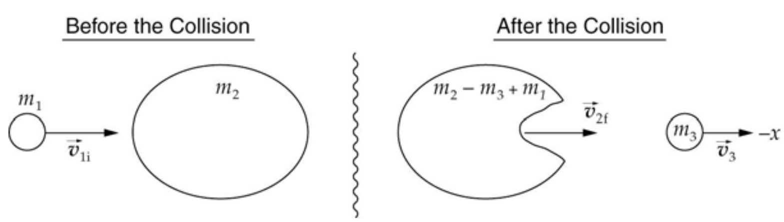
(*b*) Find the speed with which the pumpers hit the ground:

$$v_p = v_c - u_p = 10.74\,\text{m/s} - 4\,\text{m/s} = \boxed{6.74\,\text{m/s}}$$

Hitting the ground at this speed, they may be injured.

***32** ••

Picture the Problem The diagram depicts the bullet just before its collision with the melon and the motion of the melon-and-bullet-less-jet and the jet just after the collision. We'll assume that the bullet stays in the watermelon after the collision and use conservation of momentum to relate the mass of the bullet and its initial velocity to the momenta of the melon jet and the melon less the plug after the collision.



Apply conservation of momentum to the collision to obtain:

$$m_1v_{1i} = (m_2 - m_3 + m_1)v_{2f} + \sqrt{2m_3K_3}$$

Solve for v_{2f}:

$$v_{2f} = \frac{m_1v_{1i} - \sqrt{2m_3K_3}}{m_2 - m_3 + m_1}$$

Express the kinetic energy of the jet of melon in terms of the initial kinetic energy of the bullet:

$$K_3 = \tfrac{1}{10}K_1 = \tfrac{1}{10}\left(\tfrac{1}{2}m_1v_{1i}^2\right) = \tfrac{1}{20}m_1v_{1i}^2$$

Substitute and simplify to obtain:

$$v_{2f} = \frac{m_1 v_{1i} - \sqrt{2m_3\left(\frac{1}{20} m_1 v_{1i}^2\right)}}{m_2 - m_3 + m_1} = \frac{v_{1i}\left(m_1 - \sqrt{0.1 m_1 m_3}\right)}{m_2 - m_3 + m_1}$$

Substitute numerical values and evaluate v_{2f}:

$$v_{2f} = \left(1800\,\frac{\text{ft}}{\text{s}} \times \frac{1\,\text{m}}{3.281\ \text{ft}}\right)\frac{\left(0.0104\,\text{kg} - \sqrt{0.1(0.0104\,\text{kg})(0.14\,\text{kg})}\right)}{2.50\,\text{kg} - 0.14\,\text{kg} + 0.0104\,\text{kg}} = -0.386\,\text{m/s}$$

$$= \boxed{-1.27\,\text{ft/s}}$$

Note that this result is in reasonably good agreement with experimental results.

Finding the Center of Mass

33 •

Picture the Problem We can use its definition to find the center of mass of this system.

Apply its definition to find x_{cm}:

$$x_{cm} = \frac{m_1 x_1 + m_2 x_2 + m_3 x_3}{m_1 + m_2 + m_3} = \frac{(2\,\text{kg})(0) + (2\,\text{kg})(0.2\,\text{m}) + (2\,\text{kg})(0.5\,\text{m})}{2\,\text{kg} + 2\,\text{kg} + 2\,\text{kg}} = 0.233\,\text{m}$$

Because the point masses all lie along the x axis:

$y_{cm} = 0$ and the center of mass of this system of particles is at $\boxed{(0.233\,\text{m}, 0)}$.

***34** •

Picture the Problem Let the left end of the handle be the origin of our coordinate system. We can disassemble the club-ax, find the center of mass of each piece, and then use these coordinates and the masses of the handle and stone to find the center of mass of the club-ax.

Express the center of mass of the handle plus stone system:

$$x_{cm} = \frac{m_{stick} x_{cm,stick} + m_{stone} x_{cm,stone}}{m_{stick} + m_{stone}}$$

Assume that the stone is drilled and the stick passes through it. Use symmetry considerations to locate the center of mass of the stick:

$$x_{cm,stick} = 45.0\,\text{cm}$$

Use symmetry considerations to locate the center of mass of the stone:

$$x_{\text{cm,stone}} = 89.0\,\text{cm}$$

Substitute numerical values and evaluate x_{cm}:

$$x_{\text{cm}} = \frac{(2.5\,\text{kg})(45\,\text{cm}) + (8\,\text{kg})(89\,\text{cm})}{2.5\,\text{kg} + 8\,\text{kg}} = \boxed{78.5\text{cm}}$$

35 •

Picture the Problem We can treat each of balls as though they are point objects and apply the definition of the center of mass to find (x_{cm}, y_{cm}).

Use the definition of x_{cm}:

$$x_{\text{cm}} = \frac{m_A x_A + m_B x_B + m_C x_C}{m_A + m_B + m_C} = \frac{(3\,\text{kg})(2\,\text{m}) + (1\,\text{kg})(1\,\text{m}) + (1\,\text{kg})(3\,\text{m})}{3\,\text{kg} + 1\,\text{kg} + 1\,\text{kg}} = 2.00\,\text{m}$$

Use the definition of y_{cm}:

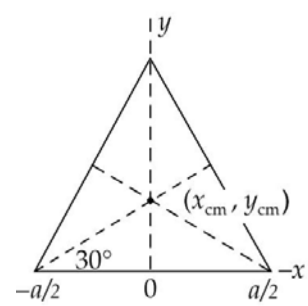
$$y_{\text{cm}} = \frac{m_A y_A + m_B y_B + m_C y_C}{m_A + m_B + m_C} = \frac{(3\,\text{kg})(2\,\text{m}) + (1\,\text{kg})(1\,\text{m}) + (1\,\text{kg})(0)}{3\,\text{kg} + 1\,\text{kg} + 1\,\text{kg}} = 1.40\,\text{m}$$

The center of mass of this system of particles is at:

$$\boxed{(2.00\,\text{m}, 1.40\,\text{m})}$$

36 •

Picture the Problem The figure shows an equilateral triangle with its y-axis vertex above the x axis. The bisectors of the vertex angles are also shown. We can find x coordinate of the center-of-mass by inspection and the y coordinate using trigonometry.



From symmetry considerations:

$$x_{\text{cm}} = 0$$

Express the trigonometric relationship between $a/2$, 30°, and y_{cm}:

$$\tan 30° = \frac{y_{cm}}{a/2}$$

Solve for y_{cm}:

$$y_{cm} = \tfrac{1}{2} a \tan 30° = 0.289a$$

The center of mass of an equilateral triangle oriented as shown above is at $\boxed{(0, 0.289a)}$.

***37 ••**

Picture the Problem Let the subscript 1 refer to the 3-m by 3-m sheet of plywood before the 2-m by 1-m piece has been cut from it. Let the subscript 2 refer to 2-m by 1-m piece that has been removed and let σ be the area density of the sheet. We can find the center-of-mass of these two regions; treating the missing region as though it had negative mass, and then finding the center-of-mass of the U-shaped region by applying its definition.

Express the coordinates of the center of mass of the sheet of plywood:

$$x_{cm} = \frac{m_1 x_{cm,1} - m_2 x_{cm,2}}{m_1 - m_2}$$

$$y_{cm} = \frac{m_1 y_{cm,1} - m_2 y_{cm,2}}{m_1 - m_2}$$

Use symmetry to find $x_{cm,1}$, $y_{cm,1}$, $x_{cm,2}$, and $y_{cm,2}$:

$$x_{cm,1} = 1.5\,\text{m},\ y_{cm,1} = 1.5\,\text{m}$$

and

$$x_{cm,2} = 1.5\,\text{m},\ y_{cm,2} = 2.0\,\text{m}$$

Determine m_1 and m_2:

$$m_1 = \sigma A_1 = 9\sigma\,\text{kg}$$

and

$$m_2 = \sigma A_2 = 2\sigma\,kg$$

Substitute numerical values and evaluate x_{cm}:

$$x_{cm} = \frac{(9\sigma\,\text{kg})(1.5\,\text{m}) - (2\sigma\,\text{kg})(1.5\,\text{kg})}{9\sigma\,\text{kg} - 2\sigma\,\text{kg}} = 1.50\,\text{m}$$

Substitute numerical values and evaluate y_{cm}:

$$y_{cm} = \frac{(9\sigma\,\text{kg})(1.5\,\text{m}) - (2\sigma\,\text{kg})(2\,\text{m})}{9\sigma\,\text{kg} - 2\sigma\,\text{kg}} = 1.36\,\text{m}$$

The center of mass of the U-shaped sheet of plywood is at $\boxed{(1.50\,\text{m}, 1.36\,\text{m})}$.

38 ••

Picture the Problem We can use its definition to find the center of mass of the can plus water. By setting the derivative of this function equal to zero, we can find the value of x that corresponds to the minimum height of the center of mass of the water as it drains out and then use this extreme value to express the minimum height of the center of mass.

(*a*) Using its definition, express the location of the center of mass of the can + water:

$$x_{cm} = \frac{M\left(\frac{H}{2}\right) + m\left(\frac{x}{2}\right)}{M + m}$$

Let the cross-sectional area of the cup be A and use the definition of density to relate the mass m of water remaining in the can at any given time to its depth x:

$$\rho = \frac{M}{AH} = \frac{m}{Ax}$$

Solve for m to obtain:

$$m = \frac{x}{H}M$$

Substitute to obtain:

$$x_{cm} = \frac{M\left(\frac{H}{2}\right) + \left(\frac{x}{H}M\right)\left(\frac{x}{2}\right)}{M + \frac{x}{H}M}$$

$$= \boxed{\frac{H}{2}\left(\frac{1 + \left(\frac{x}{H}\right)^2}{1 + \frac{x}{H}}\right)}$$

(*b*) Differentiate x_{cm} with respect to x and set the derivative equal to zero for extrema:

$$\frac{dx_{cm}}{dx} = \frac{H}{2}\frac{d}{dx}\left(\frac{1 + \left(\frac{x}{H}\right)^2}{1 + \frac{x}{H}}\right) = \frac{H}{2}\left\{\frac{\left(1 + \frac{x}{H}\right)\frac{d}{dx}\left[1 + \left(\frac{x}{H}\right)^2\right]}{\left(1 + \frac{x}{H}\right)^2} - \frac{\left[1 + \left(\frac{x}{H}\right)^2\right]\frac{d}{dx}\left(1 + \frac{x}{H}\right)}{\left(1 + \frac{x}{H}\right)^2}\right\}$$

$$= \frac{H}{2}\left\{\frac{\left(1 + \frac{x}{H}\right)2\left(\frac{x}{H}\right)\left(\frac{1}{H}\right)}{\left(1 + \frac{x}{H}\right)^2} - \frac{\left[1 + \left(\frac{x}{H}\right)^2\right]\left(\frac{1}{H}\right)}{\left(1 + \frac{x}{H}\right)^2}\right\} = 0$$

Simplify this expression to obtain:

$$\left(\frac{x}{H}\right)^2 + 2\left(\frac{x}{H}\right) - 1 = 0$$

Solve for x/H to obtain:

$$x = H\left(\sqrt{2}-1\right) \approx 0.414H$$

where we've kept the positive solution because a negative value for x/H would make no sense.

Use your graphing calculator to convince yourself that the graph of x_{cm} as a function of x is concave upward at $x \approx 0.414H$ and that, therefore, the minimum value of x_{cm} occurs at $x \approx 0.414H$.

Evaluate x_{cm} at $x = H\left(\sqrt{2}-1\right)$ to obtain:

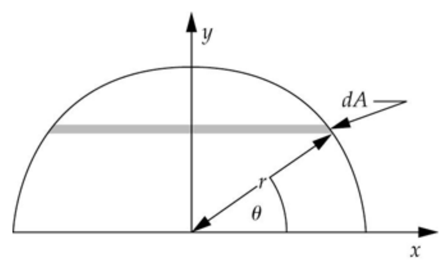
$$x_{cm}\Big|_{x=H\left(\sqrt{2}-1\right)} = \frac{H}{2}\left(\frac{1+\left(\frac{H\left(\sqrt{2}-1\right)}{H}\right)^2}{1+\frac{H\left(\sqrt{2}-1\right)}{H}}\right)$$

$$= \boxed{H\left(\sqrt{2}-1\right)}$$

Finding the Center of Mass by Integration

***39** ••

Picture the Problem A semicircular disk and a surface element of area dA is shown in the diagram. Because the disk is a continuous object, we'll use $M\vec{r}_{cm} = \int \vec{r}\,dm$ and symmetry to find its center of mass.



Express the coordinates of the center of mass of the semicircular disk:

$$x_{cm} = 0 \text{ by symmetry.}$$

$$y_{cm} = \frac{\int y\sigma\,dA}{M}$$

Express y as a function of r and θ:

$$y = r\sin\theta$$

Express dA in terms of r and θ:

$$dA = r\,d\theta\,dr$$

Express M as a function of r and θ:

$$M = \sigma A_{\text{half disk}} = \tfrac{1}{2}\sigma\pi R^2$$

Substitute and evaluate y_{cm}:

$$y_{\text{cm}} = \frac{\sigma \int_0^R \int_0^\pi r^2 \sin\theta \, d\theta \, dr}{M} = \frac{2\sigma}{M} \int_0^R r^2 dr$$

$$= \frac{2\sigma}{3M} R^3 = \boxed{\frac{4}{3\pi} R}$$

40 •••

Picture the Problem Because a solid hemisphere is a continuous object, we'll use $M\vec{r}_{\text{cm}} = \int \vec{r} dm$ to find its center of mass. The volume element for a sphere is $dV = r^2 \sin\theta \, d\theta \, d\phi \, dr$, where θ is the polar angle and ϕ the azimuthal angle.

Let the base of the hemisphere be the xy plane and ρ be the mass density. Then:

$$z = r\cos\theta$$

Express the z coordinate of the center of mass:

$$z_{\text{cm}} = \frac{\int r\rho dV}{\int \rho dV}$$

Evaluate $M = \int \rho dV$:

$$M = \int \rho dV = \tfrac{1}{2} \rho V_{\text{sphere}}$$

$$= \tfrac{1}{2}\rho\left(\tfrac{4}{3}\pi R^3\right) = \tfrac{2}{3}\pi\rho R^3$$

Evaluate $\int r\rho dV$:

$$\int r\rho dV = \int_0^R \int_0^{\pi/2} \int_0^{2\pi} r^3 \sin\theta\cos\theta d\theta d\phi dr$$

$$= \frac{\pi\rho R^4}{2}\left[\tfrac{1}{2}\sin^2\theta\right]_0^{\pi/2} = \frac{\pi\rho R^4}{4}$$

Substitute and simplify to find z_{cm}:

$$z_{\text{cm}} = \frac{\frac{1}{4}\pi\rho R^4}{\frac{2}{3}\pi\rho R^3} = \boxed{\tfrac{3}{8}R}$$

41 •••

Picture the Problem Because a thin hemisphere shell is a continuous object, we'll use $M\vec{r}_{\text{cm}} = \int \vec{r} dm$ to find its center of mass. The element of area on the shell is $dA = 2\pi R^2 \sin\theta \, d\theta$, where R is the radius of the hemisphere.

Let σ be the surface mass density and express the z coordinate of the center of mass:

$$z_{\text{cm}} = \frac{\int z\sigma \, dA}{\int \sigma \, dA}$$

Evaluate $M=\int\sigma\,dA$:

$$M=\int\sigma\,dA=\tfrac{1}{2}\sigma A_{\text{spherical shell}}$$
$$=\tfrac{1}{2}\sigma\left(4\pi R^2\right)=2\pi\sigma R^2$$

Evaluate $\int z\sigma\,dA$:

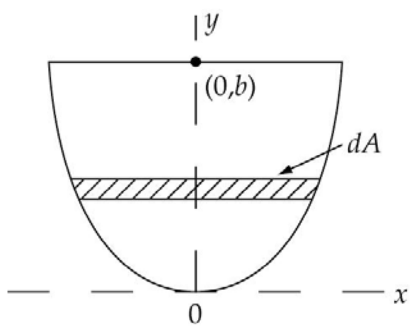
$$\int z\sigma\,dA=2\pi R^3\sigma\int_0^{\pi/2}\sin\theta\cos\theta\,d\theta$$
$$=\pi R^3\sigma\int_0^{\pi/2}\sin 2\theta\,d\theta$$
$$=\pi R^3\sigma$$

Substitute and simplify to find z_{cm}:

$$z_{\text{cm}}=\frac{\pi R^3\sigma}{2\pi\sigma R^2}=\boxed{\tfrac{1}{2}R}$$

42 •••

Picture the Problem The parabolic sheet is shown to the right. Because the area of the sheet is distributed symmetrically with respect to the y axis, $x_{\text{cm}}=0$. We'll integrate the element of area dA (= xdy) to obtain the total area of the sheet and $yxdy$ to obtain the numerator of the definition of the center of mass.



Express y_{cm}:

$$y_{\text{cm}}=\frac{\int_0^b xydy}{\int_0^b xdy}$$

Evaluate $\int_0^b xydy$:

$$\int_0^b xydy=\int_0^b\frac{y^{1/2}}{\sqrt{a}}ydy=\frac{1}{\sqrt{a}}\int_0^b y^{3/2}dy$$
$$=\frac{2}{5\sqrt{a}}b^{5/2}$$

Evaluate $\int_0^b xdy$:

$$\int_0^b xdy=\int_0^b\frac{y^{1/2}}{\sqrt{a}}dy=\frac{1}{\sqrt{a}}\int_0^b y^{1/2}dy$$
$$=\frac{2}{3\sqrt{a}}b^{3/2}$$

Substitute and simplify to determine y_{cm}:

$$y_{cm} = \frac{\frac{2}{5\sqrt{a}}b^{5/2}}{\frac{2}{3\sqrt{a}}b^{3/2}} = \tfrac{3}{5}b$$

Note that, by symmetry:

$$x_{cm} = 0$$

The center of mass of the parabolic sheet is at:

$$\boxed{\left(0, \tfrac{3}{5}b\right)}$$

Motion of the Center of Mass

43 •

Picture the Problem The velocity of the center of mass of a system of particles is related to the total momentum of the system through $\vec{\boldsymbol{P}} = \sum_{i} m_i\vec{\boldsymbol{v}}_i = M\vec{\boldsymbol{v}}_{cm}$.

Use the expression for the total momentum of a system to relate the velocity of the center of mass of the two-particle system to the momenta of the individual particles:

$$\vec{\boldsymbol{v}}_{cm} = \frac{\sum_{i} m_i\vec{\boldsymbol{v}}_i}{M} = \frac{m_1\vec{\boldsymbol{v}}_1 + m_2\vec{\boldsymbol{v}}_2}{m_1 + m_2}$$

Substitute numerical values and evaluate $\vec{\boldsymbol{v}}_{cm}$:

$$\vec{\boldsymbol{v}}_{cm} = \frac{(3\,\text{kg})(\vec{\boldsymbol{v}}_1 + \vec{\boldsymbol{v}}_2)}{6\,\text{kg}} = \tfrac{1}{2}(\vec{\boldsymbol{v}}_1 + \vec{\boldsymbol{v}}_2)$$
$$= \tfrac{1}{2}\left[(6\,\text{m/s})\hat{\boldsymbol{i}} - (3\,\text{m/s})\hat{\boldsymbol{j}}\right]$$
$$= \boxed{(3\,\text{m/s})\hat{\boldsymbol{i}} - (1.5\,\text{m/s})\hat{\boldsymbol{j}}}$$

***44** •

Picture the Problem Choose a coordinate system in which east is the positive x direction and use the relationship $\vec{\boldsymbol{P}} = \sum_{i} m_i\vec{\boldsymbol{v}}_i = M\vec{\boldsymbol{v}}_{cm}$ to determine the velocity of the center of mass of the system.

Use the expression for the total momentum of a system to relate the velocity of the center of mass of the two-vehicle system to the momenta of the individual vehicles:

$$\vec{\boldsymbol{v}}_{cm} = \frac{\sum_{i} m_i\vec{\boldsymbol{v}}_i}{M} = \frac{m_t\vec{\boldsymbol{v}}_t + m_c\vec{\boldsymbol{v}}_c}{m_t + m_c}$$

Express the velocity of the truck:

$$\vec{\boldsymbol{v}}_t = (16\,\text{m/s})\hat{\boldsymbol{i}}$$

Express the velocity of the car: $\vec{v}_c = (-20\,\text{m/s})\hat{i}$

Substitute numerical values and evaluate $\vec{v}_{cm}$:

$$\vec{v}_{cm} = \frac{(3000\,\text{kg})(16\,\text{m/s})\,\hat{i} + (1500\,\text{kg})(-20\,\text{m/s})\,\hat{i}}{3000\,\text{kg} + 1500\,\text{kg}} = \boxed{(4.00\,\text{m/s})\,\hat{i}}$$

45 •

Picture the Problem The acceleration of the center of mass of the ball is related to the net external force through Newton's 2nd law: $\vec{F}_{\text{net,ext}} = M\vec{a}_{cm}$.

Use Newton's 2nd law to express the acceleration of the ball:

$$\vec{a}_{cm} = \frac{\vec{F}_{\text{net,ext}}}{M}$$

Substitute numerical values and evaluate $\vec{a}_{cm}$:

$$\vec{a}_{cm} = \frac{(12\,\text{N})\hat{i}}{3\,\text{kg} + 1\,\text{kg} + 1\,\text{kg}} = \boxed{(2.4\,\text{m/s}^2)\hat{i}}$$

46 ••

Picture the Problem Choose a coordinate system in which upward is the positive y direction. We can use Newton's 2nd law $\vec{F}_{\text{net,ext}} = M\vec{a}_{cm}$ to find the acceleration of the center of mass of this two-body system.

(*a*) $\boxed{\text{Yes; initially the scale reads } (M+m)g\text{; while } m \text{ is in free fall, the reading is } Mg.}$

(*b*) Using Newton's 2nd law, express the acceleration of the center of mass of the system:

$$\vec{a}_{cm} = \frac{\vec{F}_{\text{net,ext}}}{m_{\text{tot}}}$$

Substitute to obtain:

$$\vec{a}_{cm} = \boxed{-\frac{mg}{M+m}\,\hat{j}}$$

(*c*) Use Newton's 2nd law to express the net force acting on the scale while the object of mass m is falling:

$$F_{\text{net,ext}} = (M+m)g - (M+m)a_{cm}$$

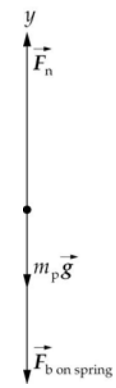
Substitute and simplify to obtain:

$$F_{\text{net,ext}} = (M+m)g - (M+m)\left(\frac{mg}{M+m}\right) = \boxed{Mg}$$

as expected, given our answer to part (*a*).

***47** ••

Picture the Problem The free-body diagram shows the forces acting on the platform when the spring is partially compressed. The scale reading is the force the scale exerts on the platform and is represented on the FBD by F_n. We can use Newton's 2nd law to determine the scale reading in part (*a*) and the work-energy theorem in conjunction with Newton's 2nd law in parts (*b*) and (*c*).



(*a*) Apply $\sum F_y = ma_y$ to the spring when it is compressed a distance *d*:

$$\sum F_y = F_n - m_p g - F_{\text{ball on spring}} = 0$$

Solve for F_n:

$$F_n = m_p g + F_{\text{ball on spring}}$$
$$= m_p g + kd = m_p g + k\left(\frac{m_b g}{k}\right)$$
$$= \boxed{m_p g + m_b g = (m_p + m_b)g}$$

(*b*) Use conservation of mechanical energy, with $U_g = 0$ at the position at which the spring is fully compressed, to relate the gravitational potential energy of the system to the energy stored in the fully compressed spring:

$$\Delta K + \Delta U_g + \Delta U_s = 0$$

Because $\Delta K = U_{g,f} = U_{s,i} = 0$,

$$U_{g,i} - U_{s,f} = 0$$

or

$$m_b g d - \tfrac{1}{2}kd^2 = 0$$

Solve for *d*:

$$d = \frac{2m_b g}{k}$$

Evaluate our force equation in (*a*) with $d = \dfrac{2m_b g}{k}$:

$$F_n = m_p g + F_{\text{ball on spring}}$$
$$= m_p g + kd = m_p g + k\left(\frac{2m_b g}{k}\right)$$
$$= \boxed{m_p g + 2m_b g = (m_p + 2m_b)g}$$

(*c*) When the ball is in its original position, the spring is relaxed and exerts no force on the ball. Therefore:

$$F_n = \text{scale reading} = \boxed{m_p g}$$

***48 ••**

Picture the Problem Assume that the object whose mass is m_1 is moving downward and take that direction to be the positive direction. We'll use Newton's 2nd law for a system of particles to relate the acceleration of the center of mass to the acceleration of the individual particles.

(*a*) Relate the acceleration of the center of mass to m_1, m_2, m_c and their accelerations:

$$M\vec{a}_{cm} = m_1\vec{a}_1 + m_2\vec{a}_2 + m_c\vec{a}_c$$

Because m_1 and m_2 have a common acceleration a and $a_c = 0$:

$$a_{cm} = a\frac{m_1 - m_2}{m_1 + m_2 + m_c}$$

From Problem 4-81 we have:

$$a = g\frac{m_1 - m_2}{m_1 + m_2}$$

Substitute to obtain:

$$a_{cm} = \left(\frac{m_1 - m_2}{m_1 + m_2}g\right)\left(\frac{m_1 - m_2}{m_1 + m_2 + m_c}\right) = \boxed{\frac{(m_1 - m_2)^2}{(m_1 + m_2)(m_1 + m_2 + m_c)}g}$$

(*b*) Use Newton's 2nd law for a system of particles to obtain:

$$F - Mg = -Ma_{cm}$$

where $M = m_1 + m_2 + m_c$ and F is positive upwards.

Solve for F and substitute for a_{cm} from part (*a*):

$$F = Mg - Ma_{cm} = Mg - \frac{(m_1 - m_2)^2}{m_1 + m_2}g = \boxed{\left[\frac{4m_1m_2}{m_1 + m_2} + m_c\right]g}$$

(*c*) From Problem 4-81:

$$T = \frac{2m_1m_2}{m_1 + m_2}g$$

Substitute in our result from part (*b*) to obtain:

$$F = \left[2\frac{2m_1m_2}{m_1+m_2} + m_c\right]g = \left[2\frac{T}{g} + m_c\right]g = \boxed{2T + m_c g}$$

49 ••

Picture the Problem The free-body diagram shows the forces acting on the platform when the spring is partially compressed. The scale reading is the force the scale exerts on the platform and is represented on the FBD by F_n. We can use Newton's 2nd law to determine the scale reading in part (*a*) and the result of Problem 7-96 part (*b*) to obtain the scale reading when the ball is dropped from a height *h* above the cup.

(*a*) Apply $\sum F_y = ma_y$ to the spring when it is compressed a distance *d*:

$$\sum F_y = F_n - m_p g - F_{\text{ball on spring}} = 0$$

Solve for F_n:

$$F_n = m_p g + F_{\text{ball on spring}} = m_p g + kd = m_p g + k\left(\frac{m_b g}{k}\right) = \boxed{m_p g + m_b g = (m_p + m_b)g}$$

(*b*) From Problem 7-96, part (*b*):

$$x_{max} = \frac{m_b g}{k}\left(1 + \sqrt{1 + \frac{2kh}{m_b g}}\right)$$

From part (*a*):

$$F_n = m_p g + F_{\text{ball on spring}} = m_p g + kx_{max} = \boxed{m_p g + m_b g\left(1 + \sqrt{1 + \frac{2kh}{m_b g}}\right)}$$

The Conservation of Momentum

50 •

Picture the Problem Let the system include the woman, the canoe, and the earth. Then the *net* external force is zero and linear momentum is conserved as she jumps off the canoe. Let the direction she jumps be the positive *x* direction.

Apply conservation of momentum to the system:

$$\sum m_i \vec{v}_i = m_{girl}\vec{v}_{girl} + m_{canoe}\vec{v}_{canoe} = 0$$

Substitute to obtain:

$$(55\,\text{kg})(2.5\,\text{m/s})\hat{i} + (75\,\text{kg})\vec{v}_{canoe} = 0$$

Solve for $\vec{v}_{canoe}$:

$$\vec{v}_{canoe} = \boxed{(-1.83\,\text{m/s})\,\hat{i}}$$

51 •

Picture the Problem If we include the earth in our system, then the net external force is zero and linear momentum is conserved as the spring delivers its energy to the two objects.

Apply conservation of momentum to the system:

$$\sum m_i \vec{v}_i = m_5\vec{v}_5 + m_{10}\vec{v}_{10} = 0$$

Substitute numerical values to obtain:

$$(5\,\text{kg})(-8\,\text{m/s})\hat{i} + (10\,\text{kg})\vec{v}_{10} = 0$$

Solve for $\vec{v}_{10}$:

$$\vec{v}_{10} = \boxed{(4\,\text{m/s})\hat{i}}$$

***52** •

Picture the Problem This is an explosion-like event in which linear momentum is conserved. Thus we can equate the initial and final momenta in the *x* direction and the initial and final momenta in the *y* direction. Choose a coordinate system in the positive *x* direction is to the right and the positive *y* direction is upward.

Equate the momenta in the *y* direction before and after the explosion:

$$\sum p_{y,i} = \sum p_{y,f} = mv_2 - 2mv_1$$
$$= m(2v_1) - 2mv_1 = 0$$

We can conclude that the momentum was entirely in the *x* direction before the particle exploded.

Equate the momenta in the *x* direction before and after the explosion:

$$\sum p_{x,i} = \sum p_{x,f}$$
$$\therefore 4mv_i = mv_3$$

Solve for v_3:

$v_i = \frac{1}{4}v_3$ and $\boxed{(c)\text{ is correct.}}$

53 •

Picture the Problem Choose the direction the shell is moving just before the explosion to be the positive x direction and apply conservation of momentum.

Use conservation of momentum to relate the masses of the fragments to their velocities:

$$\vec{p}_\text{i} = \vec{p}_\text{f}$$

or

$$mv\hat{i} = \tfrac{1}{2}mv\hat{j} + \tfrac{1}{2}m\vec{v}\,'$$

Solve for $\vec{v}\,'$:

$$\vec{v}\,' = \boxed{2v\hat{i} - v\hat{j}}$$

***54** ••

Picture the Problem Let the system include the earth and the platform, gun and block. Then $\vec{F}_\text{net,ext} = 0$ and momentum is conserved within the system.

(*a*) Apply conservation of momentum to the system just before and just after the bullet leaves the gun:

$$\vec{p}_\text{before} = \vec{p}_\text{after}$$

or

$$0 = \vec{p}_\text{bullet} + \vec{p}_\text{platform}$$

Substitute for $\vec{p}_\text{bullet}$ and $\vec{p}_\text{platform}$ and solve for $\vec{v}_\text{platform}$:

$$0 = m_\text{b}v_\text{b}\hat{i} + m_\text{p}\,\vec{v}_\text{platform}$$

and

$$\vec{v}_\text{platform} = \boxed{-\frac{m_\text{b}}{m_\text{p}}v_\text{b}\hat{i}}$$

(*b*) Apply conservation of momentum to the system just before the bullet leaves the gun and just after it comes to rest in the block:

$$\vec{p}_\text{before} = \vec{p}_\text{after}$$

or

$$0 = \vec{p}_\text{platform} \Rightarrow \vec{v}_\text{platform} = 0$$

(*c*) Express the distance Δs traveled by the platform:

$$\Delta s = v_\text{platform}\Delta t$$

Express the velocity of the bullet relative to the platform:

$$v_\text{rel} = v_\text{b} - v_\text{platform} = v_\text{b} + \frac{m_\text{b}}{m_\text{p}}v_\text{b}$$

$$= \left(1 + \frac{m_\text{b}}{m_\text{p}}\right)v_\text{b} = \frac{m_\text{p} + m_\text{b}}{m_\text{p}}v_\text{b}$$

Relate the time of flight Δt to L and v_rel:

$$\Delta t = \frac{L}{v_\text{rel}}$$

Substitute to find the distance Δs moved by the platform in time Δt:

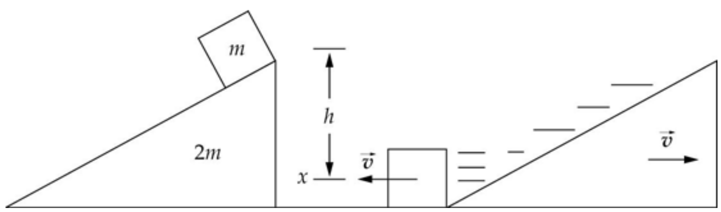
$$\Delta s = v_{\text{platform}}\Delta t = \left(\frac{m_{\text{b}}}{m_{\text{p}}}v_{\text{b}}\right)\left(\frac{L}{v_{\text{rel}}}\right)$$

$$= \left(\frac{m_{\text{b}}}{m_{\text{p}}}v_{\text{b}}\right)\left(\frac{L}{\frac{m_{\text{p}}+m_{\text{b}}}{m_{\text{p}}}v_{\text{b}}}\right)$$

$$= \boxed{\frac{m_{\text{b}}}{m_{\text{p}}+m_{\text{b}}}L}$$

55 ••

Picture the Problem The pictorial representation shows the wedge and small object, initially at rest, to the left, and, to the right, both in motion as the small object leaves the wedge. Choose the direction the small object is moving when it leaves the wedge be the positive *x* direction and the zero of potential energy to be at the surface of the table. Let the speed of the small object be *v* and that of the wedge *V*. We can use conservation of momentum to express *v* in terms of *V* and conservation of energy to express *v* in terms of *h*.



Apply conservation of momentum to the small object and the wedge:

$$\vec{p}_{\text{i},x} = \vec{p}_{\text{f},x}$$

or

$$0 = mv\hat{i} + 2m\vec{V}$$

Solve for $\vec{V}$:

$$\vec{V} = -\tfrac{1}{2}v\hat{i} \qquad (1)$$

and

$$V = \tfrac{1}{2}v$$

Use conservation of energy to determine the speed of the small object when it exits the wedge:

$$\Delta K + \Delta U = 0$$

or

$$K_{\text{f}} - K_{\text{i}} + U_{\text{f}} - U_{\text{i}} = 0$$

Because $U_{\text{f}} = K_{\text{i}} = 0$:

$$\tfrac{1}{2}mv^2 + \tfrac{1}{2}(2m)V^2 - mgh = 0$$

Substitute for V to obtain:

$$\tfrac{1}{2}mv^2 + \tfrac{1}{2}(2m)\left(\tfrac{1}{2}v\right)^2 - mgh = 0$$

Solve for v to obtain:

$$v = 2\sqrt{\frac{gh}{3}}$$

Substitute in equation (1) to determine $\vec{V}$:

$$\vec{V} = -\tfrac{1}{2}\left(2\sqrt{\frac{gh}{3}}\right)\hat{i} = \boxed{-\sqrt{\frac{gh}{3}}\,\hat{i}}$$

i.e., the wedge moves in the direction opposite to that of the small object with a speed of $\sqrt{\frac{gh}{3}}$.

***56 ••**

Picture the Problem Because no external forces act on either cart, the center of mass of the two-cart system can't move. We can use the data concerning the masses and separation of the gliders initially to calculate its location and then apply the definition of the center of mass a second time to relate the positions X_1 and X_2 of the centers of the carts when they first touch. We can also use the separation of the centers of the gliders when they touch to obtain a second equation in X_1 and X_2 that we can solve simultaneously with the equation obtained from the location of the center of mass.

(*a*) Apply its definition to find the center of mass of the 2-glider system:

$$x_{cm} = \frac{m_1x_1 + m_2x_2}{m_1 + m_2} = \frac{(0.1\,\text{kg})(0.1\,\text{m}) + (0.2\,\text{kg})(1.6\,\text{m})}{0.1\,\text{kg} + 0.2\,\text{kg}} = 1.10\,\text{m}$$

from the left end of the air track.

Use the definition of the center of mass to relate the coordinates of the centers of the two gliders when they first touch to the location of the center of mass:

$$1.10\,\text{m} = \frac{m_1X_1 + m_2X_2}{m_1 + m_2} = \frac{(0.1\,\text{kg})X_1 + (0.2\,\text{kg})X_2}{0.1\,\text{kg} + 0.2\,\text{kg}} = \tfrac{1}{3}X_1 + \tfrac{2}{3}X_2$$

Also, when they first touch, their centers are separated by half their combined lengths:

$$X_2 - X_1 = \tfrac{1}{2}(10\,\text{cm} + 20\,\text{cm}) = 0.15\,\text{m}$$

Thus we have:

$$0.333X_1 + 0.667X_2 = 1.10\,\text{m}$$

and

$$X_2 - X_1 = 0.15\,\text{m}$$

Solve these equations simultaneously to obtain:

$$X_1 = \boxed{1.00\,\text{m}} \text{ and } X_2 = \boxed{1.15\,\text{m}}$$

(*b*)

No. The initial momentum of the system is zero, so it must be zero after the collision.

Kinetic Energy of a System of Particles

***57** •

Picture the Problem Choose a coordinate system in which the positive *x* direction is to the right. Use the expression for the total momentum of a system to find the velocity of the center of mass and the definition of relative velocity to express the sum of the kinetic energies relative to the center of mass.

(*a*) Find the sum of the kinetic energies:

$$\begin{aligned} K &= K_1 + K_2 \\ &= \tfrac{1}{2}m_1v_1^2 + \tfrac{1}{2}m_2v_2^2 \\ &= \tfrac{1}{2}(3\,\text{kg})(5\,\text{m/s})^2 + \tfrac{1}{2}(3\,\text{kg})(2\,\text{m/s})^2 \\ &= \boxed{43.5\,\text{J}} \end{aligned}$$

(*b*) Relate the velocity of the center of mass of the system to its total momentum:

$$M\vec{\boldsymbol{v}}_{\text{cm}} = m_1\vec{\boldsymbol{v}}_1 + m_2\vec{\boldsymbol{v}}_2$$

Solve for $\vec{\boldsymbol{v}}_{\text{cm}}$:

$$\vec{\boldsymbol{v}}_{\text{cm}} = \frac{m_1\vec{\boldsymbol{v}}_1 + m_2\vec{\boldsymbol{v}}_2}{m_1 + m_2}$$

Substitute numerical values and evaluate $\vec{\boldsymbol{v}}_{\text{cm}}$:

$$\begin{aligned} \vec{\boldsymbol{v}}_{\text{cm}} &= \frac{(3\,\text{kg})(5\,\text{m/s})\hat{\boldsymbol{i}} - (3\,\text{kg})(2\,\text{m/s})\hat{\boldsymbol{i}}}{3\,\text{kg} + 3\,\text{kg}} \\ &= \boxed{(1.50\,\text{m/s})\hat{\boldsymbol{i}}} \end{aligned}$$

(*c*) The velocity of an object relative to the center of mass is given by:

$$\vec{\boldsymbol{v}}_{\text{rel}} = \vec{\boldsymbol{v}} - \vec{\boldsymbol{v}}_{\text{cm}}$$

Substitute numerical values to obtain:

$$\vec{v}_{1,\text{rel}} = (5\,\text{m/s})\hat{i} - (1.5\,\text{m/s})\hat{i} = \boxed{(3.50\,\text{m/s})\hat{i}}$$

$$\vec{v}_{2,\text{rel}} = (-2\,\text{m/s})\hat{i} - (1.5\,\text{m/s})\hat{i} = \boxed{(-3.50\,\text{m/s})\hat{i}}$$

(*d*) Express the sum of the kinetic energies relative to the center of mass:

$$K_{\text{rel}} = K_{1,\text{rel}} + K_{2,\text{rel}} = \tfrac{1}{2}m_1v_{1,\text{rel}}^2 + \tfrac{1}{2}m_2v_{2,\text{rel}}^2$$

Substitute numerical values and evaluate K_{rel}:

$$K_{\text{rel}} = \tfrac{1}{2}(3\,\text{kg})(3.5\,\text{m/s})^2 + \tfrac{1}{2}(3\,\text{kg})(-3.5\,\text{m/s})^2 = \boxed{36.75\,\text{J}}$$

(*e*) Find K_{cm}:

$$K_{\text{cm}} = \tfrac{1}{2}m_{\text{tot}}v_{\text{cm}}^2 = \tfrac{1}{2}(6\,\text{kg})(1.5\,\text{m/s})^2 = 6.75\,\text{J} = 43.5\,\text{J} - 36.75\,\text{J} = \boxed{K - K_{\text{rel}}}$$

58 •

Picture the Problem Choose a coordinate system in which the positive *x* direction is to the right. Use the expression for the total momentum of a system to find the velocity of the center of mass and the definition of relative velocity to express the sum of the kinetic energies relative to the center of mass.

(*a*) Express the sum of the kinetic energies:

$$K = K_1 + K_2 = \tfrac{1}{2}m_1v_1^2 + \tfrac{1}{2}m_2v_2^2$$

Substitute numerical values and evaluate *K*:

$$K = \tfrac{1}{2}(3\,\text{kg})(5\,\text{m/s})^2 + \tfrac{1}{2}(5\,\text{kg})(3\,\text{m/s})^2 = \boxed{60.0\,\text{J}}$$

(*b*) Relate the velocity of the center of mass of the system to its total momentum:

$$M\vec{v}_{\text{cm}} = m_1\vec{v}_1 + m_2\vec{v}_2$$

Solve for $\vec{v}_{\text{cm}}$:

$$\vec{v}_{\text{cm}} = \frac{m_1\vec{v}_1 + m_2\vec{v}_2}{m_1 + m_2}$$

Substitute numerical values and evaluate $\vec{v}_{cm}$:

$$\vec{v}_{cm} = \frac{(3\,\text{kg})(5\,\text{m/s})\hat{\boldsymbol{i}} + (5\,\text{kg})(3\,\text{m/s})\hat{\boldsymbol{i}}}{3\,\text{kg} + 5\,\text{kg}} = \boxed{(3.75\,\text{m/s})\hat{\boldsymbol{i}}}$$

(*c*) The velocity of an object relative to the center of mass is given by:

$$\vec{v}_{rel} = \vec{v} - \vec{v}_{cm}$$

Substitute numerical values and evaluate the relative velocities:

$$\vec{v}_{1,rel} = (5\,\text{m/s})\hat{\boldsymbol{i}} - (3.75\,\text{m/s})\hat{\boldsymbol{i}} = \boxed{(1.25\,\text{m/s})\hat{\boldsymbol{i}}}$$

and

$$\vec{v}_{2,rel} = (3\,\text{m/s})\hat{\boldsymbol{i}} - (3.75\,\text{m/s})\hat{\boldsymbol{i}} = \boxed{(-0.750\,\text{m/s})\hat{\boldsymbol{i}}}$$

(*d*) Express the sum of the kinetic energies relative to the center of mass:

$$K_{rel} = K_{1,rel} + K_{2,rel} = \tfrac{1}{2}m_1 v_{1,rel}^2 + \tfrac{1}{2}m_2 v_{2,rel}^2$$

Substitute numerical values and evaluate K_{rel}:

$$K_{rel} = \tfrac{1}{2}(3\,\text{kg})(1.25\,\text{m/s})^2 + \tfrac{1}{2}(5\,\text{kg})(-0.75\,\text{m/s})^2 = \boxed{3.75\,\text{J}}$$

(*e*) Find K_{cm}:

$$K_{cm} = \tfrac{1}{2}m_{tot}v_{cm}^2 = \tfrac{1}{2}(8\,\text{kg})(3.75\,\text{m/s})^2 = 56.3\,\text{J} = \boxed{K - K_{rel}}$$

Impulse and Average Force

59 •

Picture the Problem The impulse imparted to the ball by the kicker equals the *change* in the ball's momentum. The impulse is also the product of the average force exerted on the ball by the kicker and the time during which the average force acts.

(*a*) Relate the impulse delivered to the ball to its change in momentum:

$$I = \Delta p = p_f - p_i = mv_f \;\text{ since } v_i = 0$$

Substitute numerical values and evaluate *I*:

$$I = (0.43\,\text{kg})(25\,\text{m/s}) = \boxed{10.8\,\text{N}\cdot\text{s}}$$

(*b*) Express the impulse delivered to the ball as a function of the average force acting on it and solve for and evaluate F_{av}:

$$I = F_{av}\Delta t$$

and

$$F_{av} = \frac{I}{\Delta t} = \frac{10.8\,\text{N}\cdot\text{s}}{0.008\,\text{s}} = \boxed{1.34\,\text{kN}}$$

60 •

Picture the Problem The impulse exerted by the ground on the brick equals the *change* in momentum of the brick and is also the product of the average force exerted by the ground on the brick and the time during which the average force acts.

(*a*) Express the impulse exerted by the ground on the brick:

$$I = \left|\Delta p_{brick}\right| = \left|p_{f,brick} - p_{i,brick}\right|$$

Because $p_{f,brick} = 0$:

$$I = p_{i,brick} = m_{brick}v \qquad (1)$$

Use conservation of energy to determine the speed of the brick at impact:

$$\Delta K + \Delta U = 0$$

or

$$K_f - K_i + U_f - U_i = 0$$

Because $U_f = K_i = 0$:

$$K_f - U_i = 0$$

or

$$\tfrac{1}{2}m_{brick}v^2 - m_{brick}gh = 0$$

Solve for v:

$$v = \sqrt{2gh}$$

Substitute in equation (1) to obtain:

$$I = m_{brick}\sqrt{2gh}$$

Substitute numerical values and evaluate I:

$$I = (0.3\,\text{kg})\sqrt{2(9.81\,\text{m/s}^2)(8\,\text{m})} = \boxed{3.76\,\text{N}\cdot\text{s}}$$

(*c*) Express the impulse delivered to the brick as a function of the average force acting on it and solve for and evaluate F_{av}:

$$I = F_{av}\Delta t$$

and

$$F_{av} = \frac{I}{\Delta t} = \frac{3.76\,\text{N}\cdot\text{s}}{0.0013\,\text{s}} = \boxed{2.89\,\text{kN}}$$

***61** •

Picture the Problem The impulse exerted by the ground on the meteorite equals the *change* in momentum of the meteorite and is also the product of the average force exerted by the ground on the meteorite and the time during which the average force acts.

Express the impulse exerted by the ground on the meteorite:

$$I = \Delta p_{\text{meteorite}} = p_{\text{f}} - p_{\text{i}}$$

Relate the kinetic energy of the meteorite to its initial momentum and solve for its initial momentum:

$$K_{\text{i}} = \frac{p_{\text{i}}^2}{2m} \Rightarrow p_{\text{i}} = \sqrt{2mK_{\text{i}}}$$

Express the ratio of the initial and final kinetic energies of the meteorite:

$$\frac{K_{\text{i}}}{K_{\text{f}}} = \frac{\dfrac{p_{\text{i}}^2}{2m}}{\dfrac{p_{\text{f}}^2}{2\text{m}}} = \frac{p_{\text{i}}^2}{p_{\text{f}}^2} = 2$$

Solve for p_{f}:

$$p_{\text{f}} = \frac{p_{\text{i}}}{\sqrt{2}}$$

Substitute in our expression for I and simplify:

$$I = \frac{p_{\text{i}}}{\sqrt{2}} - p_{\text{i}} = p_{\text{i}}\left(\frac{1}{\sqrt{2}} - 1\right)$$
$$= \sqrt{2mK_{\text{i}}}\left(\frac{1}{\sqrt{2}} - 1\right)$$

Because our interest is in its magnitude, evaluate $|I|$:

$$|I| = \left|\sqrt{2(30.8\times10^3\ \text{kg})(617\times10^6\ \text{J})}\left(\frac{1}{\sqrt{2}} - 1\right)\right| = \boxed{1.81\,\text{MN}\cdot\text{s}}$$

Express the impulse delivered to the meteorite as a function of the average force acting on it and solve for and evaluate F_{av}:

$$I = F_{\text{av}}\Delta t$$

and

$$F_{\text{av}} = \frac{I}{\Delta t} = \frac{1.81\,\text{MN}\cdot\text{s}}{3\text{s}} = \boxed{0.602\,\text{MN}}$$

62 ••

Picture the Problem The impulse exerted by the bat on the ball equals the *change* in momentum of the ball and is also the product of the average force exerted by the bat on the ball and the time during which the bat and ball were in contact.

(*a*) Express the impulse exerted by the bat on the ball in terms of the change in momentum of the ball:

$$\vec{\boldsymbol{I}} = \Delta\vec{\boldsymbol{p}}_{\text{ball}} = \vec{\boldsymbol{p}}_{\text{f}} - \vec{\boldsymbol{p}}_{\text{i}}$$
$$= mv_{\text{f}}\hat{\boldsymbol{i}} - \left(-mv_{\text{i}}\hat{\boldsymbol{i}}\right) = 2mv\hat{\boldsymbol{i}}$$

where $v = v_{\text{f}} = v_{\text{i}}$

Substitute for *m* and *v* and evaluate *I*:

$$I = 2(0.15\,\text{kg})(20\,\text{m/s}) = \boxed{6.00\,\text{N}\cdot\text{s}}$$

(*b*) Express the impulse delivered to the ball as a function of the average force acting on it and solve for and evaluate F_{av}:

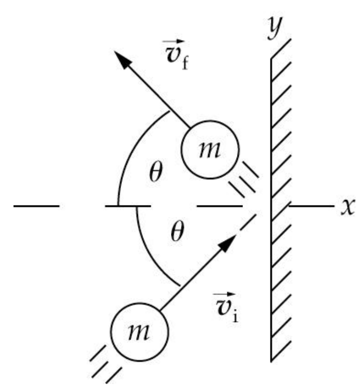
$$I = F_{\text{av}}\Delta t$$

and

$$F_{\text{av}} = \frac{I}{\Delta t} = \frac{6.00\,\text{N}\cdot\text{s}}{1.3\,\text{ms}} = \boxed{4.62\,\text{kN}}$$

***63 ••**

Picture the Problem The figure shows the handball just before and immediately after its collision with the wall. Choose a coordinate system in which the positive *x* direction is to the right. The wall changes the momentum of the ball by exerting a force on it during the ball's collision with it. The reaction to this force is the force the ball exerts on the wall. Because these action and reaction forces are equal in magnitude, we can find the average force exerted on the ball by finding the change in momentum of the ball.



Using Newton's 3rd law, relate the average force exerted by the ball on the wall to the average force exerted by the wall on the ball:

$$\vec{F}_{\text{av on wall}} = -\vec{F}_{\text{av on ball}}$$

and

$$F_{\text{av on wall}} = F_{\text{av on ball}} \qquad (1)$$

Relate the average force exerted by the wall on the ball to its change in momentum:

$$\vec{F}_{\text{av on ball}} = \frac{\Delta\vec{p}}{\Delta t} = \frac{m\Delta\vec{v}}{\Delta t}$$

Express $\Delta\vec{v}_x$ for the ball:

$$\Delta\vec{v}_x = v_{\text{f},x}\hat{i} - v_{\text{i},x}\hat{i}$$

or, because $v_{\text{i},x} = v\cos\theta$ and $v_{\text{f},x} = -v\cos\theta$,

$$\Delta\vec{v}_x = -v\cos\theta\,\hat{i} - v\cos\theta\,\hat{i} = -2v\cos\theta\,\hat{i}$$

Substitute in our expression for $\vec{F}_{\text{av on ball}}$:

$$\vec{F}_{\text{av on ball}} = \frac{m\Delta\vec{v}}{\Delta t} = -\frac{2mv\cos\theta}{\Delta t}\hat{i}$$

Evaluate the magnitude of $\vec{F}_{\text{av on ball}}$:

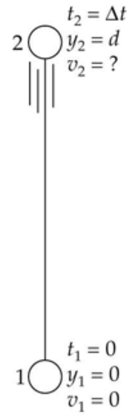
$$F_{\text{av on ball}} = \frac{2mv\cos\theta}{\Delta t} = \frac{2(0.06\,\text{kg})(5\,\text{m/s})\cos 40°}{2\,\text{ms}} = 230\,\text{N}$$

Substitute in equation (1) to obtain:

$$F_{\text{av on wall}} = \boxed{230\,\text{N}}$$

64 ••

Picture the Problem The pictorial representation shows the ball during the interval of time you are exerting a force on it to accelerate it upward. The average force you exert can be determined from the change in momentum of the ball. The change in the velocity of the ball can be found by applying conservation of mechanical energy to its rise in the air once it has left your hand.



(*a*) Relate the average force exerted by your hand on the ball to the change in momentum of the ball:

$$F_{\text{av}} = \frac{\Delta p}{\Delta t} = \frac{p_2 - p_1}{\Delta t} = \frac{mv_2}{\Delta t}$$

because v_1 and, hence, $p_1 = 0$.

Letting $U_g = 0$ at the initial elevation of your hand, use conservation of mechanical energy to relate the initial kinetic energy of the ball to its potential energy when it is at its highest point:

$$\Delta K + \Delta U = 0$$

or

$$-K_i + U_f = 0$$

since $K_f = U_i = 0$

Substitute for K_f *and* U_i and solve for v_2:

$$-\tfrac{1}{2}mv_2^2 + mgh = 0$$

and

$$v_2 = \sqrt{2gh}$$

Relate Δt to the average speed of the ball while you are throwing it upward:

$$\Delta t = \frac{d}{v_{\text{av}}} = \frac{d}{\frac{v_2}{2}} = \frac{2d}{v_2}$$

Substitute for Δt and v_2 in the expression for F_{av} to obtain:

$$F_{av} = \frac{mgh}{d}$$

Substitute numerical values and evaluate F_{av}:

$$F_{av} = \frac{(0.15\,\text{kg})(9.81\,\text{m/s}^2)(40\,\text{m})}{0.7\,\text{m}} = \boxed{84.1\,\text{N}}$$

(*b*) Express the ratio of the weight of the ball to the average force acting on it:

$$\frac{w}{F_{av}} = \frac{mg}{F_{av}} = \frac{(0.15\,\text{kg})(9.81\,\text{m/s}^2)}{84.1\,\text{N}} < 2\%$$

$$\boxed{\text{Because the weight of the ball is less than 2\% of the average force exerted on the ball, it is reasonable to have neglected its weight.}}$$

65 ••

Picture the Problem Choose a coordinate system in which the direction the ball is moving *after* its collision with the wall is the positive *x* direction. The impulse delivered to the wall or received by the player equals the change in the momentum of the ball. We can find the average forces from the rate of change in the momentum of the ball.

(*a*) Relate the impulse delivered to the wall to the change in momentum of the handball:

$$\vec{I} = \Delta\vec{p} = m\vec{v}_f - m\vec{v}_i = (0.06\,\text{kg})(8\,\text{m/s})\hat{i} - \left[-(0.06\,\text{kg})(10\,\text{m/s})\hat{i}\right] = \boxed{(1.08\,\text{N}\cdot\text{s})\hat{i}\text{ directed into wall.}}$$

(*b*) Find F_{av} from the change in the ball's momentum:

$$F_{av} = \frac{\Delta p}{\Delta t} = \frac{1.08\,\text{N}\cdot\text{s}}{0.003\,\text{s}} = \boxed{360\,\text{N, into wall.}}$$

(*c*) Find the impulse received by the player from the change in momentum of the ball:

$$I = \Delta p_{ball} = m\Delta v = (0.06\,\text{kg})(8\,\text{m/s}) = \boxed{0.480\,\text{N}\cdot\text{s, away from wall.}}$$

(*d*) Relate F_{av} to the change in the ball's momentum:

$$F_{av} = \frac{\Delta p_{ball}}{\Delta t}$$

Express the stopping time in terms of the average speed v_{av} of the ball

$$\Delta t = \frac{d}{v_{av}}$$

and its stopping distance *d*:

Substitute to obtain:

$$F_{av} = \frac{v_{av}\Delta p_{ball}}{d}$$

Substitute numerical values and evaluate F_{av}:

$$F_{av} = \frac{(4\,\text{m/s})(0.480\,\text{N}\cdot\text{s})}{0.5\,\text{m}} = \boxed{3.84\,\text{N, away from wall.}}$$

66 •••

Picture the Problem The average force exerted on the limestone by the droplets of water equals the rate at which momentum is being delivered to the floor. We're given the number of droplets that arrive per minute and can use conservation of mechanical energy to determine their velocity as they reach the floor.

(*a*) Letting *N* represent the rate at which droplets fall, relate F_{av} to the change in the droplet's momentum:

$$F_{av} = \frac{\Delta p_{droplets}}{\Delta t} = N\frac{m\Delta v}{\Delta t}$$

Find the mass of the droplets:

$$m = \rho V = (1\,\text{kg/L})(0.03\,\text{mL}) = 3\times10^{-5}\,\text{kg}$$

Letting $U_g = 0$ at the point of impact of the droplets, use conservation of mechanical energy to relate their speed at impact to their fall distance:

$$\Delta K + \Delta U = 0$$

or

$$K_f - K_i + U_f - U_i = 0$$

Because $K_i = U_f = 0$:

$$\tfrac{1}{2}mv_f^2 - mgh = 0$$

Solve for and evaluate $v = v_f$:

$$v = \sqrt{2gh} = \sqrt{2(9.81\,\text{m/s}^2)(5\,\text{m})} = 9.90\,\text{m/s}$$

Substitute numerical values and evaluate F_{av}:

$$F_{av} = \left(\frac{N}{\Delta t}\right)m\Delta v$$

$$= \left(10\frac{\text{droplets}}{\text{min}}\times\frac{1\,\text{min}}{60\,\text{s}}\right)\times(3\times10^{-5}\,\text{kg})(9.90\,\text{m/s})$$

$$= \boxed{4.95\times10^{-5}\,\text{N}}$$

(*b*) Calculate the ratio of the weight of a droplet to F_{av}:

$$\frac{w}{F_{\text{av}}}=\frac{mg}{F_{\text{av}}}=\frac{(3\times10^{-5}\text{ kg})(9.81\text{ m/s}^2)}{4.95\times10^{-5}\text{ N}}\approx\boxed{6}$$

Collisions in One Dimension

***67** •

Picture the Problem We can apply conservation of momentum to this perfectly inelastic collision to find the after-collision speed of the two cars. The ratio of the transformed kinetic energy to kinetic energy before the collision is the fraction of kinetic energy lost in the collision.

(*a*) Letting *V* be the velocity of the two cars after their collision, apply conservation of momentum to their perfectly inelastic collision:

$$p_{\text{initial}}=p_{\text{final}}$$

or

$$mv_1+mv_2=(m+m)V$$

Solve for and evaluate *V*:

$$V=\frac{v_1+v_2}{2}=\frac{30\text{ m/s}+10\text{ m/s}}{2}=\boxed{20.0\text{ m/s}}$$

(*b*) Express the ratio of the kinetic energy that is lost to the kinetic energy of the two cars before the collision and simplify:

$$\frac{\Delta K}{K_{\text{initial}}}=\frac{K_{\text{final}}-K_{\text{initial}}}{K_{\text{initial}}}=\frac{K_{\text{final}}}{K_{\text{initial}}}-1=\frac{\frac{1}{2}(2m)V^2}{\frac{1}{2}mv_1^2+\frac{1}{2}mv_2^2}-1=\frac{2V^2}{v_1^2+v_2^2}-1$$

Substitute numerical values to obtain:

$$\frac{\Delta K}{K_{\text{initial}}}=\frac{2(20\text{ m/s})^2}{(30\text{ m/s})^2+(10\text{ m/s})^2}-1=-0.200$$

$$\boxed{\text{20\% of the initial kinetic energy is transformed into heat, sound, and the deformation of metal.}}$$

68 •

Picture the Problem We can apply conservation of momentum to this perfectly inelastic collision to find the after-collision speed of the two players.

Letting the subscript 1 refer to the running back and the subscript 2 refer to the linebacker, apply conservation of momentum to their perfectly inelastic collision:

$$p_i = p_f$$

or

$$m_1 v_1 = (m_1 + m_2)V$$

Solve for V:

$$V = \frac{m_1}{m_1 + m_2} v_1$$

Substitute numerical values and evaluate V:

$$V = \frac{85\,\text{kg}}{85\,\text{kg} + 105\,\text{kg}}(7\,\text{m/s}) = \boxed{3.13\,\text{m/s}}$$

69 •

Picture the Problem We can apply conservation of momentum to this collision to find the after-collision speed of the 5-kg object. Let the direction the 5-kg object is moving before the collision be the positive direction. We can decide whether the collision was elastic by examining the initial and final kinetic energies of the system.

(*a*) Letting the subscript 5 refer to the 5-kg object and the subscript 2 refer to the 10-kg object, apply conservation of momentum to obtain:

$$p_i = p_f$$

or

$$m_5 v_{i,5} - m_{10} v_{i,10} = m_5 v_{f,5}$$

Solve for $v_{f,5}$:

$$v_{f,5} = \frac{m_5 v_{i,5} - m_{10} v_{i,10}}{m_5}$$

Substitute numerical values and evaluate $v_{f,5}$:

$$v_{f,5} = \frac{(5\,\text{kg})(4\,\text{m/s}) - (10\,\text{kg})(3\,\text{m/s})}{5\,\text{kg}}$$

$$= \boxed{-2.00\,\text{m/s}}$$

where the minus sign means that the 5-kg object is moving to the left after the collision.

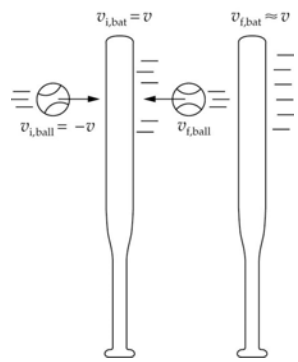
(*b*) Evaluate ΔK for the collision:

$$\Delta K = K_f - K_i = \tfrac{1}{2}(5\,\text{kg})(2\,\text{m/s})^2 - \left[\tfrac{1}{2}(5\,\text{kg})(4\,\text{m/s})^2 + \tfrac{1}{2}(10\,\text{kg})(3\,\text{m/s})^2\right] = -75.0\,\text{J}$$

$$\boxed{\text{Because } \Delta K \neq 0, \text{ the collision was inelastic.}}$$

70 •

Picture the Problem The pictorial representation shows the ball and bat just before and just after their collision. Take the direction the bat is moving to be the positive direction. Because the collision is elastic, we can equate the speeds of recession and approach, with the approximation that $v_{i,bat} \approx v_{f,bat}$ to find $v_{f,ball}$.



Express the speed of approach of the bat and ball:

$$v_{f,bat} - v_{f,ball} = -(v_{i,bat} - v_{i,ball})$$

Because the mass of the bat is much greater than that of the ball:

$$v_{i,bat} \approx v_{f,bat}$$

Substitute to obtain:

$$v_{f,bat} - v_{f,ball} = -(v_{f,bat} - v_{i,ball})$$

Solve for and evaluate $v_{f,ball}$:

$$v_{f,ball} = v_{f,bat} + (v_{f,bat} - v_{i,ball}) = -v_{i,ball} + 2v_{f,bat} = v + 2v = \boxed{3v}$$

***71** ••

Picture the Problem Let the direction the proton is moving before the collision be the positive *x* direction. We can use both conservation of momentum and conservation of mechanical energy to obtain an expression for velocity of the proton after the collision.

(*a*) Use the expression for the total momentum of a system to find v_{cm}:

$$\vec{P} = \sum_i m_i \vec{v}_i = M\vec{v}_{cm}$$

and

$$\vec{v}_{cm} = \frac{m\vec{v}_{p,i}}{m + 12m} = \tfrac{1}{13}(300\,\text{m/s})\hat{i} = \boxed{(23.1\,\text{m/s})\hat{i}}$$

(*b*) Use conservation of momentum to obtain one relation for the final velocities:

$$m_p v_{p,i} = m_p v_{p,f} + m_{nuc} v_{nuc,f} \quad (1)$$

Use conservation of mechanical energy to set the velocity of recession equal to the negative of the velocity of approach:

$$v_{nuc,f} - v_{p,f} = -(v_{nuc,i} - v_{p,i}) = v_{p,i} \quad (2)$$

To eliminate $v_{nuc,f}$, solve equation (2) for $v_{nuc,f}$, and substitute the result in equation (1):

$$v_{nuc,f} = v_{p,i} + v_{p,f}$$

$$m_p v_{p,i} = m_p v_{p,f} + m_{nuc}(v_{p,i} + v_{p,f})$$

Solve for and evaluate $v_{p,f}$:

$$v_{p,f} = \frac{m_p - m_{nuc}}{m_p + m_{nuc}} v_{p,i}$$

$$= \frac{m - 12m}{13m}(300\,\text{m/s}) = \boxed{-254\,\text{m/s}}$$

72 ••

Picture the Problem We can use conservation of momentum and the definition of an elastic collision to obtain two equations in v_{2f} and v_{3f} that we can solve simultaneously.

Use conservation of momentum to obtain one relation for the final velocities:

$$m_3 v_{3i} = m_3 v_{3f} + m_2 v_{2f} \quad (1)$$

Use conservation of mechanical energy to set the velocity of recession equal to the negative of the velocity of approach:

$$v_{2f} - v_{3f} = -(v_{2i} - v_{3i}) = v_{3i} \quad (2)$$

Solve equation (2) for v_{3f} , substitute in equation (1) to eliminate v_{3f}, and solve for and evaluate v_{2f}:

$$v_{2f} = \frac{2m_3 v_{3i}}{m_2 + m_3} = \frac{2(3\,\text{kg})(4\,\text{m/s})}{2\,\text{kg} + 3\,\text{kg}}$$

$$= \boxed{4.80\,\text{m/s}}$$

Use equation (2) to find v_{3f}:

$$v_{3f} = v_{2f} - v_{3i} = 4.80\,\text{m/s} - 4.00\,\text{m/s}$$

$$= \boxed{0.800\,\text{m/s}}$$

Evaluate K_i and K_f:

$$K_i = K_{3i} = \tfrac{1}{2} m_3 v_{3i}^2 = \tfrac{1}{2}(3\,\text{kg})(4\,\text{m/s})^2$$

$$= 24.0\,\text{J}$$

and

$$K_f = K_{3f} + K_{2f} = \tfrac{1}{2}m_3v_{3f}^2 + \tfrac{1}{2}m_2v_{2f}^2$$
$$= \tfrac{1}{2}(3\,\text{kg})(0.8\,\text{m/s})^2 + \tfrac{1}{2}(2\,\text{kg})(4.8\,\text{m/s})^2$$
$$= 24.0\,\text{J}$$

Because $K_i = K_f$, we can conclude that the values obtained for v_{2f} and v_{3f} are consistent with the collision having been elastic.

73 ••

Picture the Problem We can find the velocity of the center of mass from the definition of the total momentum of the system. We'll use conservation of energy to find the maximum compression of the spring and express the initial (i.e., before collision) and final (i.e., at separation) velocities. Finally, we'll transform the velocities from the center of mass frame of reference to the table frame of reference.

(*a*) Use the definition of the total momentum of a system to relate the initial momenta to the velocity of the center of mass:

$$\vec{P} = \sum_i m_i\vec{v}_i = M\vec{v}_{cm}$$

or

$$m_1v_{1i} = (m_1 + m_2)v_{cm}$$

Solve for v_{cm}:

$$v_{cm} = \frac{m_1v_{1i} + m_2v_{2i}}{m_1 + m_2}$$

Substitute numerical values and evaluate v_{cm}:

$$v_{cm} = \frac{(2\,\text{kg})(10\,\text{m/s}) + (5\,\text{kg})(3\,\text{m/s})}{2\,\text{kg} + 5\,\text{kg}} = \boxed{5.00\,\text{m/s}}$$

(*b*) Find the kinetic energy of the system at maximum compression ($u_1 = u_2 = 0$):

$$K = K_{cm} = \tfrac{1}{2}Mv_{cm}^2 = \tfrac{1}{2}(7\,\text{kg})(5\,\text{m/s})^2 = 87.5\,\text{J}$$

Use conservation of energy to relate the kinetic energy of the system to the potential energy stored in the spring at maximum compression:

$$\Delta K + \Delta U_s = 0$$

or

$$K_f - K_i + U_{sf} - U_{si} = 0$$

Because $K_f = K_{cm}$ and $U_{si} = 0$:

$$K_{cm} - K_i + \tfrac{1}{2}k(\Delta x)^2 = 0$$

Solve for Δx:

$$\Delta x = \sqrt{\frac{2(K_\text{i} - K_\text{cm})}{k}} = \sqrt{\frac{2\left[\frac{1}{2}m_1v_{1\text{i}}^2 + \frac{1}{2}m_2v_{2\text{i}}^2 - K_\text{cm}\right]}{k}} = \sqrt{\frac{m_1v_{1\text{i}}^2 + m_2v_{2\text{i}}^2 - 2K_\text{cm}}{k}}$$

Substitute numerical values and evaluate Δx:

$$\Delta x = \sqrt{\left[\frac{(2\,\text{kg})(10\,\text{m/s})^2 + (5\,\text{kg})(3\,\text{m/s})^2}{1120\,\text{N/m}} - \frac{2(87.5\,\text{J})}{1120\,\text{N/m}}\right]} = \boxed{0.250\,\text{m}}$$

(*c*) Find $u_{1\text{i}}$, $u_{2\text{i}}$, and $u_{1\text{f}}$ for this elastic collision:

$$u_{1\text{i}} = v_{1\text{i}} - v_\text{cm} = 10\,\text{m/s} - 5\,\text{m/s} = 5\,\text{m/s},$$
$$u_{2\text{i}} = v_{2\text{i}} - v_\text{cm} = 3\,\text{m/s} - 5\,\text{m/s} = -2\,\text{m/s},$$
and
$$u_{1\text{f}} = v_{1\text{f}} - v_\text{cm} = 0 - 5\,\text{m/s} = -5\,\text{m/s}$$

Use conservation of mechanical energy to set the velocity of recession equal to the negative of the velocity of approach and solve for $u_{2\text{f}}$:

$$u_{2\text{f}} - u_{1\text{f}} = -(u_{2\text{i}} - u_{1\text{i}})$$
and
$$u_{2\text{f}} = -u_{2\text{i}} + u_{1\text{i}} + u_{1\text{f}} = -(-2\,\text{m/s}) + 5\,\text{m/s} - 5\,\text{m/s} = 2\,\text{m/s}$$

Transform $u_{1\text{f}}$ and $u_{2\text{f}}$ to the table frame of reference:

$$v_{1\text{f}} = u_{1\text{f}} + v_\text{cm} = -5\,\text{m/s} + 5\,\text{m/s} = \boxed{0}$$
and
$$v_{2\text{f}} = u_{2\text{f}} + v_\text{cm} = 2\,\text{m/s} + 5\,\text{m/s} = \boxed{7.00\,\text{m/s}}$$

***74 ••**

Picture the Problem Let the system include the earth, the bullet, and the sheet of plywood. Then $W_\text{ext} = 0$. Choose the zero of gravitational potential energy to be where the bullet enters the plywood. We can apply both conservation of energy and conservation of momentum to obtain the various physical quantities called for in this problem.

(*a*) Use conservation of mechanical energy after the bullet exits the sheet of plywood to relate its exit speed to the height to which it rises:

$$\Delta K + \Delta U = 0$$
or, because $K_\text{f} = U_\text{i} = 0$,
$$-\tfrac{1}{2}mv_m^2 + mgh = 0$$

Solve for v_m:

$$v_m = \boxed{\sqrt{2gh}}$$

Proceed similarly to relate the initial velocity of the plywood to the height to which it rises:

$$v_M = \boxed{\sqrt{2gH}}$$

(b) Apply conservation of momentum to the collision of the bullet and the sheet of plywood:

$$\vec{\boldsymbol{p}}_\text{i} = \vec{\boldsymbol{p}}_\text{f}$$

or

$$mv_{m\text{i}} = mv_m + Mv_M$$

Substitute for v_m and v_M and solve for $v_{m\text{i}}$:

$$v_{m\text{i}} = \boxed{\sqrt{2gh} + \frac{M}{m}\sqrt{2gH}}$$

(c) Express the initial mechanical energy of the system (i.e., just before the collision):

$$E_\text{i} = \tfrac{1}{2}mv_{m\text{i}}^2$$

$$= \boxed{mg\left[h + \frac{2M}{m}\sqrt{hH} + \left(\frac{M}{m}\right)^2 H\right]}$$

Express the final mechanical energy of the system (i.e., when the bullet and block have reached their maximum heights):

$$E_\text{f} = mgh + MgH = \boxed{g(mh + MH)}$$

(d) Use the work-energy theorem with $W_\text{ext} = 0$ to find the energy dissipated by friction in the inelastic collision:

$$E_\text{f} - E_\text{i} + W_\text{friction} = 0$$

and

$$W_\text{friction} = E_\text{i} - E_\text{f}$$

$$= \boxed{gMH\left[2\sqrt{\frac{h}{H}} + \frac{M}{m} - 1\right]}$$

75 ••

Picture the Problem We can find the velocity of the center of mass from the definition of the total momentum of the system. We'll use conservation of energy to find the speeds of the particles when their separation is least and when they are far apart.

(a) Noting that when the distance between the two particles is least, both move at the same speed, namely v_cm, use the definition of the total momentum of a system to relate the initial momenta to the velocity of

$$\vec{\boldsymbol{P}} = \sum_i m_i \vec{\boldsymbol{v}}_i = M\vec{\boldsymbol{v}}_\text{cm}$$

or

$$m_\text{p}v_\text{pi} = (m_\text{p} + m_\alpha)v_\text{cm}\,.$$

the center of mass:

Solve for and evaluate v_{cm}:

$$v_{cm} = v' = \frac{m_p v_{pi} + m_\alpha v_{\alpha i}}{m_1 + m_2} = \frac{mv_0 + 0}{m + 4m}$$
$$= \boxed{0.200\,v_0}$$

(*b*) Use conservation of momentum to obtain one relation for the final velocities:

$$m_p v_0 = m_p v_{pf} + m_\alpha v_{\alpha f} \qquad (1)$$

Use conservation of mechanical energy to set the velocity of recession equal to the negative of the velocity of approach:

$$v_{pf} - v_{\alpha f} = -\left(v_{pi} - v_{\alpha i}\right) = -v_{pi} \qquad (2)$$

Solve equation (2) for v_{pf} , substitute in equation (1) to eliminate v_{pf}, and solve for $v_{\alpha f}$:

$$v_{\alpha f} = \frac{2m_p v_0}{m_p + m_\alpha} = \frac{2mv_0}{m + 4m} = \boxed{0.400\,v_0}$$

76 •

Picture the Problem Let the numeral 1 denote the electron and the numeral 2 the hydrogen atom. We can find the final velocity of the electron and, hence, the fraction of its initial kinetic energy that is transferred to the atom, by transforming to the center-of-mass reference frame, calculating the post-collision velocity of the electron, and then transforming back to the laboratory frame of reference.

Express *f*, the fraction of the electron’s initial kinetic energy that is transferred to the atom:

$$f = \frac{K_i - K_f}{K_i} = 1 - \frac{K_f}{K_i}$$
$$= 1 - \frac{\frac{1}{2}m_1 v_{1f}^2}{\frac{1}{2}m_1 v_{1i}^2} = 1 - \left(\frac{v_{1f}}{v_{1i}}\right)^2 \qquad (1)$$

Find the velocity of the center of mass:

$$v_{cm} = \frac{m_1 v_{1i}}{m_1 + m_2}$$

or, because $m_2 = 1840m_1$,

$$v_{cm} = \frac{m_1 v_{1i}}{m_1 + 1840m_1} = \frac{1}{1841}v_{1i}$$

Find the initial velocity of the electron in the center-of-mass reference frame:

$$u_{1i} = v_{1i} - v_{cm} = v_{1i} - \frac{1}{1841}v_{1i}$$
$$= \left(1 - \frac{1}{1841}\right)v_{1i}$$

Find the post-collision velocity of the electron in the center-of-mass reference frame by reversing its velocity:

$$u_{1f} = -u_{1i} = \left(\frac{1}{1841} - 1\right)v_{1i}$$

To find the final velocity of the electron in the original frame, add v_{cm} to its final velocity in the center-of-mass reference frame:

$$v_{1f} = u_{1f} + v_{cm} = \left(\frac{2}{1841} - 1\right)v_{1i}$$

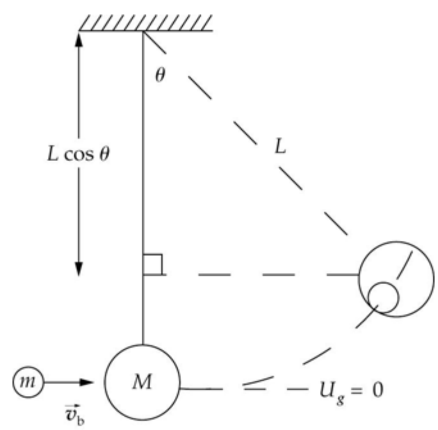
Substitute in equation (1) to obtain:

$$f = 1 - \left(\frac{\left(\frac{2}{1841} - 1\right)v_{1i}}{v_{1i}}\right)^2 = 1 - \left(\frac{2}{1841} - 1\right)^2$$

$$= 2.17\times10^{-3} = \boxed{0.217\%}$$

77 ••

Picture the Problem The pictorial representation shows the bullet about to imbed itself in the bob of the ballistic pendulum and then, later, when the bob plus bullet have risen to their maximum height. We can use conservation of momentum during the collision to relate the speed of the bullet to the initial speed of the bob plus bullet (V). The initial kinetic energy of the bob plus bullet is transformed into gravitational potential energy when they reach their maximum height. Hence we apply conservation of mechanical energy to relate V to the angle through which the bullet plus bob swings and then solve the momentum and energy equations simultaneously for the speed of the bullet.



Use conservation of momentum to relate the speed of the bullet just before impact to the initial speed of the bob plus bullet:

$$mv_b = (m+M)V$$

Solve for the speed of the bullet:

$$v_b = \left(1 + \frac{M}{m}\right)V \qquad (1)$$

Use conservation of energy to relate

$$\Delta K + \Delta U = 0$$

the initial kinetic energy of the bullet to the final potential energy of the system:

or, because $K_f = U_i = 0$,

$$-K_i + U_f = 0$$

Substitute for K_i and U_f and solve for V:

$$-\tfrac{1}{2}(m+M)V^2 + (m+M)gL(1-\cos\theta) = 0$$

and

$$V = \sqrt{2gL(1-\cos\theta)}$$

Substitute for V in equation (1) to obtain:

$$v_b = \left(1+\frac{M}{m}\right)\sqrt{2gL(1-\cos\theta)}$$

Substitute numerical values and evaluate v_b:

$$v_b = \left(1+\frac{1.5\,\text{kg}}{0.016\,\text{kg}}\right)\sqrt{2(9.81\,\text{m/s}^2)(2.3\,\text{m})(1-\cos 60°)} = \boxed{450\,\text{m/s}}$$

***78 ••**

Picture the Problem We can apply conservation of momentum and the definition of an elastic collision to obtain equations relating the initial and final velocities of the colliding objects that we can solve for v_{1f} and v_{2f}.

Apply conservation of momentum to the elastic collision of the particles to obtain:

$$m_1v_{1f} + m_2v_{2f} = m_1v_{1i} + m_2v_{2i} \qquad (1)$$

Relate the initial and final kinetic energies of the particles in an elastic collision:

$$\tfrac{1}{2}m_1v_{1f}^2 + \tfrac{1}{2}m_2v_{2f}^2 = \tfrac{1}{2}m_1v_{1i}^2 + \tfrac{1}{2}m_2v_{2i}^2$$

Rearrange this equation and factor to obtain:

$$m_2\left(v_{2f}^2 - v_{2i}^2\right) = m_1\left(v_{1i}^2 - v_{1f}^2\right)$$

or

$$m_2(v_{2f}-v_{2i})(v_{2f}+v_{2i}) = m_1(v_{1i}-v_{1f})(v_{1i}+v_{1f}) \qquad (2)$$

Rearrange equation (1) to obtain:

$$m_2(v_{2f}-v_{2i}) = m_1(v_{1i}-v_{1f}) \qquad (3)$$

Divide equation (2) by equation (3) to obtain:

$$v_{2f} + v_{2i} = v_{1i} + v_{1f}$$

Rearrange this equation to obtain equation (4):

$$v_{1f} - v_{2f} = v_{2i} - v_{1i} \qquad (4)$$

Multiply equation (4) by m_2 and add it to equation (1) to obtain:

$$(m_1+m_2)v_{1f} = (m_1-m_2)v_{1i} + 2m_2v_{2i}$$

Solve for v_{1f} to obtain:

$$v_{1f} = \boxed{\frac{m_1 - m_2}{m_1 + m_2} v_{1i} + \frac{2m_2}{m_1 + m_2} v_{2i}}$$

Multiply equation (4) by m_1 and subtract it from equation (1) to obtain:

$$(m_1 + m_2) v_{2f} = (m_2 - m_1) v_{2i} + 2m_1 v_{1i}$$

Solve for v_{2f} to obtain:

$$v_{2f} = \boxed{\frac{2m_1}{m_1 + m_2} v_{1i} + \frac{m_2 - m_1}{m_1 + m_2} v_{2i}}$$

Remarks: Note that the velocities satisfy the condition that $\boldsymbol{v}_{2f} - \boldsymbol{v}_{1f} = -(\boldsymbol{v}_{2i} - \boldsymbol{v}_{1i})$. This verifies that the speed of recession equals the speed of approach.

79 ••

Picture the Problem As in this problem, Problem 78 involves an elastic, one-dimensional collision between two objects. Both solutions involve using the conservation of momentum equation $m_1 v_{1f} + m_2 v_{2f} = m_1 v_{1i} + m_2 v_{2i}$ and the elastic collision equation $v_{1f} - v_{2f} = v_{2i} - v_{1i}$. In part (*a*) we can simply set the masses equal to each other and substitute in the equations in Problem 78 to show that the particles "swap" velocities. In part (*b*) we can divide the numerator and denominator of the equations in Problem 78 by m_2 and use the condition that $m_2 >> m_1$ to show that $v_{1f} \approx -v_{1i} + 2v_{2i}$ and $v_{2f} \approx v_{2i}$.

(*a*) From Problem 78 we have:

$$v_{1f} = \frac{m_1 - m_2}{m_1 + m_2} v_{1i} + \frac{2m_2}{m_1 + m_2} v_{2i} \quad (1)$$

and

$$v_{2f} = \frac{2m_1}{m_1 + m_2} v_{1i} + \frac{m_2 - m_1}{m_1 + m_2} v_{2i} \quad (2)$$

Set $m_1 = m_2 = m$ to obtain:

$$v_{1f} = \frac{2m}{m + m} v_{2i} = \boxed{v_{2i}}$$

and

$$v_{2f} = \frac{2m}{m + m} v_{1i} = \boxed{v_{1i}}$$

(*b*) Divide the numerator and denominator of both terms in equation (1) by m_2 to obtain:

$$v_{1f} = \frac{\frac{m_1}{m_2} - 1}{\frac{m_1}{m_2} + 1} v_{1i} + \frac{2}{\frac{m_1}{m_2} + 1} v_{2i}$$

If $m_2 >> m_1$:

$$v_{1f} \approx \boxed{-v_{1i} + 2v_{2i}}$$

Divide the numerator and denominator of both terms in equation (2) by m_2 to obtain:

$$v_{2f} = \frac{2\frac{m_1}{m_2}}{\frac{m_1}{m_2}+1}v_{1i} + \frac{1-\frac{m_1}{m_2}}{\frac{m_1}{m_2}+1}v_{2i}$$

If $m_2 >> m_1$:

$$v_{2f} \approx \boxed{v_{2i}}$$

Remarks: Note that, in both parts of this problem, the velocities satisfy the condition that $v_{2f} - v_{1f} = -(v_{2i} - v_{1i})$. This verifies that the speed of recession equals the speed of approach.

Perfectly Inelastic Collisions and the Ballistic Pendulum

80 ••

Picture the Problem Choose $U_g = 0$ at the bob's equilibrium position. Momentum is conserved in the collision of the bullet with bob and the initial kinetic energy of the bob plus bullet is transformed into gravitational potential energy as it swings up to the top of the circle. If the bullet plus bob just makes it to the top of the circle with zero speed, it will swing through a complete circle.

Use conservation of momentum to relate the speed of the bullet just before impact to the initial speed of the bob plus bullet:

$$m_1 v = (m_1 + m_2)V$$

Solve for the speed of the bullet:

$$v = \left(1 + \frac{m_2}{m_1}\right)V \qquad (1)$$

Use conservation of energy to relate the initial kinetic energy of the bob plus bullet to their potential energy at the top of the circle:

$$\Delta K + \Delta U = 0$$

or, because $K_f = U_i = 0$,

$$-K_i + U_f = 0$$

Substitute for K_i and U_f:

$$-\tfrac{1}{2}(m_1 + m_2)V^2 + (m_1 + m_2)g(2L) = 0$$

Solve for V:

$$V = \sqrt{gL}$$

Substitute for V in equation (1) and simplify to obtain:

$$v = \boxed{\left(1 + \frac{m_2}{m_1}\right)\sqrt{gL}}$$

***81 ••**

Picture the Problem Choose $U_g = 0$ at the equilibrium position of the ballistic pendulum. Momentum is conserved in the collision of the bullet with the bob and kinetic energy is transformed into gravitational potential energy as the bob swings up to its maximum height.

Letting V represent the initial speed of the bob as it begins its upward swing, use conservation of momentum to relate this speed to the speeds of the bullet just before and after its collision with the bob:

$$m_1 v = m_1\left(\tfrac{1}{2}v\right) + m_2 V$$

Solve for the speed of the bob:

$$V = \frac{m_1}{2m_2}v \qquad (1)$$

Use conservation of energy to relate the initial kinetic energy of the bob to its potential energy at its maximum height:

$$\Delta K + \Delta U = 0$$

or, because $K_f = U_i = 0$,

$$-K_i + U_f = 0$$

Substitute for K_i and U_f:

$$-\tfrac{1}{2}m_2 V^2 + m_2 gh = 0$$

Solve for h:

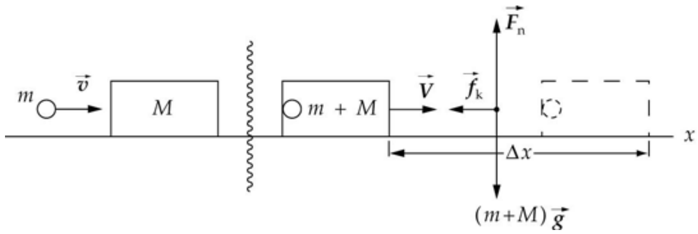
$$h = \frac{V^2}{2g} \qquad (2)$$

Substitute V from equation (1) in equation (2) and simplify to obtain:

$$h = \frac{\left(\frac{m_1}{2m_2}v\right)^2}{2g} = \boxed{\frac{v^2}{8g}\left(\frac{m_1}{m_2}\right)^2}$$

82 •

Picture the Problem Let the mass of the bullet be m, that of the wooden block M, the pre-collision velocity of the bullet v, and the post-collision velocity of the block+bullet be V. We can use conservation of momentum to find the velocity of the block with the bullet imbedded in it just after their perfectly inelastic collision. We can use Newton's 2^{nd} law to find the acceleration of the sliding block and a constant-acceleration equation to find the distance the block slides.



Using a constant-acceleration equation, relate the velocity of the block+bullet just after their collision to their acceleration and displacement before stopping:

$$0 = V^2 + 2a\Delta x$$

because the final velocity of the block+bullet is zero.

Solve for the distance the block slides before coming to rest:

$$\Delta x = -\frac{V^2}{2a} \quad (1)$$

Use conservation of momentum to relate the pre-collision velocity of the bullet to the post-collision velocity of the block+bullet:

$$mv = (m+M)V$$

Solve for *V*:

$$V = \frac{m}{m+M}v$$

Substitute in equation (1) to obtain:

$$\Delta x = -\frac{1}{2a}\left(\frac{m}{m+M}v\right)^2 \quad (2)$$

Apply $\sum \vec{F} = m\vec{a}$ to the block+bullet (see the FBD in the diagram):

$$\sum F_x = -f_k = (m+M)a \quad (3)$$

and

$$\sum F_y = F_n - (m+M)g = 0 \quad (4)$$

Use the definition of the coefficient of kinetic friction and equation (4) to obtain:

$$f_k = \mu_k F_n = \mu_k (m+M)g$$

Substitute in equation (3):

$$-\mu_k (m+M)g = (m+M)a$$

Solve for *a* to obtain:

$$a = -\mu_k g$$

Substitute in equation (2) to obtain:

$$\Delta x = \frac{1}{2\mu_k g}\left(\frac{m}{m+M}v\right)^2$$

Substitute numerical values and evaluate Δx:

$$\Delta x = \frac{1}{2(0.22)(9.81\,\text{m/s}^2)}\left(\frac{0.0105\,\text{kg}}{0.0105\,\text{kg}+10.5\,\text{kg}}(750\,\text{m/s})\right)^2 = \boxed{0.130\,\text{m}}$$

83 ••

Picture the Problem The collision of the ball with the box is perfectly inelastic and we can find the speed of the box-and-ball immediately after their collision by applying conservation of momentum. If we assume that the kinetic friction force is constant, we can use a constant-acceleration equation to find the acceleration of the box and ball combination and the definition of μ_k to find its value.

Using its definition, express the coefficient of kinetic friction of the table:

$$\mu_k = \frac{f_k}{F_n} = \frac{(M+m)|a|}{(M+m)g} = \frac{|a|}{g} \quad (1)$$

Use conservation of momentum to relate the speed of the ball just before the collision to the speed of the ball+box immediately after the collision:

$$MV = (m+M)v$$

Solve for v:

$$v = \frac{MV}{m+M} \quad (2)$$

Use a constant-acceleration equation to relate the sliding distance of the ball+box to its initial and final velocities and its acceleration:

$$v_f^2 = v_i^2 + 2a\Delta x$$

or, because $v_f = 0$ and $v_i = v$,

$$0 = v^2 + 2a\Delta x$$

Solve for a:

$$a = -\frac{v^2}{2\Delta x}$$

Substitute in equation (1) to obtain:

$$\mu_k = \frac{v^2}{2g\Delta x}$$

Use equation (2) to eliminate v:

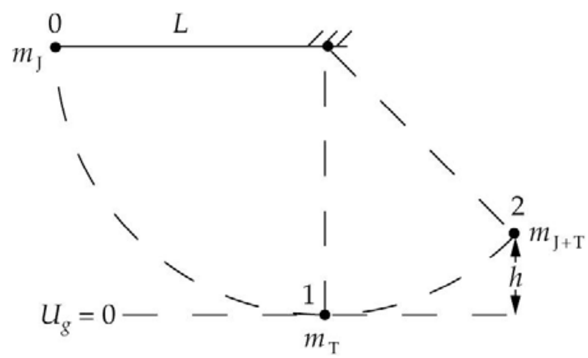
$$\mu_k = \frac{1}{2g\Delta x}\left(\frac{MV}{m+M}\right)^2 = \frac{1}{2g\Delta x}\left(\frac{V}{\frac{m}{M}+1}\right)^2$$

Substitute numerical values and evaluate μ_k:

$$\mu_k = \frac{1}{2(9.81\,\text{m/s}^2)(0.52\,\text{m})}\left(\frac{1.3\,\text{m/s}}{\frac{0.327\,\text{kg}}{0.425\,\text{kg}}+1}\right)^2 = \boxed{0.0529}$$

***84 ••**

Picture the Problem Jane's collision with Tarzan is a perfectly inelastic collision. We can find her speed v_1 just before she grabs Tarzan from conservation of energy and their speed V just after she grabs him from conservation of momentum. Their kinetic energy just after their collision will be transformed into gravitational potential energy when they have reached their greatest height h.



Use conservation of energy to relate the potential energy of Jane and Tarzan at their highest point (2) to their kinetic energy immediately after Jane grabbed Tarzan:

$$U_2 = K_1$$

or

$$m_{J+T}gh = \tfrac{1}{2}m_{J+T}V^2$$

Solve for h to obtain:

$$h = \frac{V^2}{2g} \qquad (1)$$

Use conservation of momentum to relate Jane's velocity just before she collides with Tarzan to their velocity just after their perfectly inelastic collision:

$$m_J v_1 = m_{J+T}V$$

Solve for V:

$$V = \frac{m_J}{m_{J+T}}v_1 \qquad (2)$$

Apply conservation of energy to relate Jane's kinetic energy at 1 to her potential energy at 0:

$$K_1 = U_0$$

or

$$\tfrac{1}{2}m_J v_1^2 = m_J gL$$

Solve for v_1:

$$v_1 = \sqrt{2gL}$$

Substitute in equation (2) to obtain:

$$V = \frac{m_J}{m_{J+T}}\sqrt{2gL}$$

Substitute in equation (1) and simplify:

$$h = \frac{1}{2g}\left(\frac{m_J}{m_{J+T}}\right)^2 2gL = \left(\frac{m_J}{m_{J+T}}\right)^2 L$$

Substitute numerical values and evaluate h:

$$h = \left(\frac{54\,\text{kg}}{54\,\text{kg} + 82\,\text{kg}}\right)^2 (25\,\text{m}) = \boxed{3.94\,\text{m}}$$

Exploding Objects and Radioactive Decay

85 ••

Picture the Problem This nuclear reaction is $^4\text{Be} \rightarrow 2\alpha + 1.5{\times}10^{-14}$ J. In order to conserve momentum, the alpha particles will have move in opposite directions with the same velocities. We'll use conservation of energy to find their speeds.

Letting E represent the energy released in the reaction, express conservation of energy for this process:

$$2K_\alpha = 2\left(\tfrac{1}{2}m_\alpha v_\alpha^2\right) = E$$

Solve for v_α:

$$v_\alpha = \sqrt{\frac{E}{m_\alpha}}$$

Substitute numerical values and evaluate v_α:

$$v_\alpha = \sqrt{\frac{1.5\times10^{-14}\text{ J}}{6.68\times10^{-27}\text{ kg}}} = \boxed{1.50\times10^{6}\text{ m/s}}$$

86 ••

Picture the Problem This nuclear reaction is $^5\text{Li} \rightarrow \alpha + \text{p} + 3.15 \times 10^{-13}$ J. To conserve momentum, the alpha particle and proton must move in opposite directions. We'll apply both conservation of energy and conservation of momentum to find the speeds of the proton and alpha particle.

Use conservation of momentum in this process to express the alpha particle's velocity in terms of the proton's:

$$p_i = p_f = 0$$

and

$$0 = m_p v_p - m_\alpha v_\alpha$$

Solve for v_α and substitute for m_α to obtain:

$$v_\alpha = \frac{m_p}{m_\alpha} v_p = \frac{m_p}{4m_p} v_p = \tfrac{1}{4} v_p$$

Letting E represent the energy released in the reaction, apply conservation of energy to the process:

$$K_p + K_\alpha = E$$

or

$$\tfrac{1}{2} m_p v_p^2 + \tfrac{1}{2} m_\alpha v_\alpha^2 = E$$

Substitute for v_α:

$$\tfrac{1}{2} m_p v_p^2 + \tfrac{1}{2} m_\alpha \left(\tfrac{1}{4} v_p\right)^2 = E$$

Solve for v_p and substitute for m_α to obtain:

$$v_p = \sqrt{\frac{32E}{16m_p + m_\alpha}} = \sqrt{\frac{32E}{16m_p + 4m_p}}$$

Substitute numerical values and evaluate v_p:

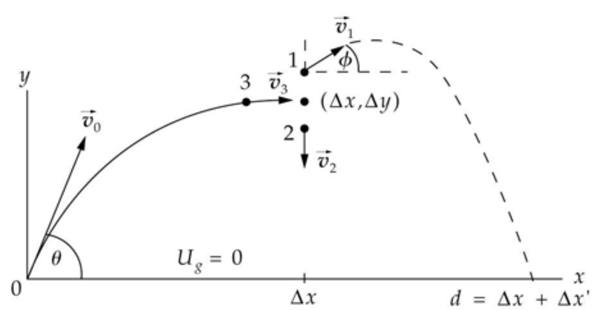
$$v_p = \sqrt{\frac{32\left(3.15\times10^{-13}\text{ J}\right)}{20\left(1.67\times10^{-27}\text{ kg}\right)}} = \boxed{1.74\times10^{7}\text{ m/s}}$$

Use the relationship between v_p and v_α to obtain v_α:

$$v_\alpha = \tfrac{1}{4} v_p = \tfrac{1}{4}\left(1.74\times10^{7}\text{ m/s}\right) = \boxed{4.34\times10^{6}\text{ m/s}}$$

87 •••

Picture the Problem The pictorial representation shows the projectile at its maximum elevation and is moving horizontally. It also shows the two fragments resulting from the explosion. We chose the system to include the projectile and the earth so that no external forces act to change the momentum of the system during the explosion. With this choice of system we can also use conservation of energy to determine the elevation of the projectile when it explodes. We'll also find it useful to use constant-acceleration equations in our description of the motion of the projectile and its fragments.



(*a*) Use conservation of momentum to relate the velocity of the projectile before its explosion to the velocities of its two parts after the explosion:

$$\vec{p}_i = \vec{p}_f$$
$$m_3\vec{v}_3 = m_1\vec{v}_1 + m_2\vec{v}_2$$
$$m_3v_3\hat{i} = m_1v_{x1}\hat{i} + m_1v_{y1}\hat{j} - m_2v_{y2}\hat{j}$$

The only way this equality can hold is if:

$$m_3v_3 = m_1v_{x1}$$
and
$$m_1v_{y1} = m_2v_{y2}$$

Express v_3 in terms of v_0 and substitute for the masses to obtain:

$$v_{x1} = 3v_3 = 3v_0\cos\theta$$
$$= 3(120\,\text{m/s})\cos 30° = 312\,\text{m/s}$$
and
$$v_{y1} = 2v_{y2} \quad (1)$$

Using a constant-acceleration equation with the downward direction positive, relate v_{y2} to the time it takes the 2-kg fragment to hit the ground:

$$\Delta y = v_{y2}\Delta t + \tfrac{1}{2}g(\Delta t)^2$$
$$v_{y2} = \frac{\Delta y - \frac{1}{2}g(\Delta t)^2}{\Delta t} \quad (2)$$

With $U_g = 0$ at the launch site, apply conservation of energy to the climb of the projectile to its maximum elevation:

$$\Delta K + \Delta U = 0$$
Because $K_f = U_i = 0$, $-K_i + U_f = 0$
or
$$-\tfrac{1}{2}m_3v_{y0}^2 + m_3g\Delta y = 0$$

Solve for Δy:

$$\Delta y = \frac{v_{y0}^2}{2g} = \frac{(v_0\sin 30°)^2}{2g}$$

Substitute numerical values and evaluate Δy:

$$\Delta y = \frac{[(120\,\text{m/s})\sin 30°]^2}{2(9.81\,\text{m/s}^2)} = 183.5\,\text{m}$$

Substitute in equation (2) and evaluate v_{y2}:

$$v_{y2} = \frac{183.5\,\text{m} - \frac{1}{2}(9.81\,\text{m/s}^2)(3.6\,\text{s})^2}{3.6\,\text{s}}$$
$$= 33.3\,\text{m/s}$$

Substitute in equation (1) and evaluate v_{y1}:

$$v_{y1} = 2(33.3\,\text{m/s}) = 66.6\,\text{m/s}$$

Express $\vec{v}_1$ in vector form:

$$\vec{v}_1 = v_{x1}\hat{i} + v_{y1}\hat{j} = \boxed{(312\,\text{m/s})\hat{i} + (66.6\,\text{m/s})\hat{j}}$$

(*b*) Express the total distance *d* traveled by the 1-kg fragment:

$$d = \Delta x + \Delta x' \qquad (3)$$

Relate Δx to v_0 and the time-to-explosion:

$$\Delta x = (v_0 \cos\theta)(\Delta t_{\text{exp}}) \qquad (4)$$

Using a constant-acceleration equation, express Δt_{exp}:

$$\Delta t_{\text{exp}} = \frac{v_{y0}}{g} = \frac{v_0 \sin\theta}{g}$$

Substitute numerical values and evaluate Δt_{exp}:

$$\Delta t_{\text{exp}} = \frac{(120\,\text{m/s})\sin 30°}{9.81\,\text{m/s}^2} = 6.12\,\text{s}$$

Substitute in equation (4) and evaluate Δx:

$$\Delta x = (120\,\text{m/s})(\cos 30°)(6.12\,\text{s}) = 636.5\,\text{m}$$

Relate the distance traveled by the 1-kg fragment after the explosion to the time it takes it to reach the ground:

$$\Delta x' = v_{x1}\Delta t'$$

Using a constant-acceleration equation, relate the time $\Delta t'$ for the 1-kg fragment to reach the ground to its initial speed in the *y* direction and the distance to the ground:

$$\Delta y = v_{y1}\Delta t' - \tfrac{1}{2} g (\Delta t')^2$$

Substitute to obtain the quadratic equation:

$$(\Delta t')^2 - (13.6\,\text{s})\Delta t' - 37.4\,\text{s}^2 = 0$$

Solve the quadratic equation to find $\Delta t'$:

$$\Delta t' = 15.9\text{ s}$$

Substitute in equation (3) and evaluate *d*:

$$d = \Delta x + \Delta x' = \Delta x + v_{x1}\Delta t' = 636.5\,\text{m} + (312\,\text{m/s})(15.9\,\text{s}) = \boxed{5.61\,\text{km}}$$

(*c*) Express the energy released in the explosion:

$$E_{exp} = \Delta K = K_f - K_i \quad (5)$$

Find the kinetic energy of the fragments after the explosion:

$$K_f = K_1 + K_2 = \tfrac{1}{2}m_1v_1^2 + \tfrac{1}{2}m_2v_2^2$$
$$= \tfrac{1}{2}(1\,\text{kg})\left[(312\,\text{m/s})^2 + (66.6\,\text{m/s})^2\right]$$
$$+ \tfrac{1}{2}(2\,\text{kg})(33.3\,\text{m/s})^2$$
$$= 52.0\,\text{kJ}$$

Find the kinetic energy of the projectile before the explosion:

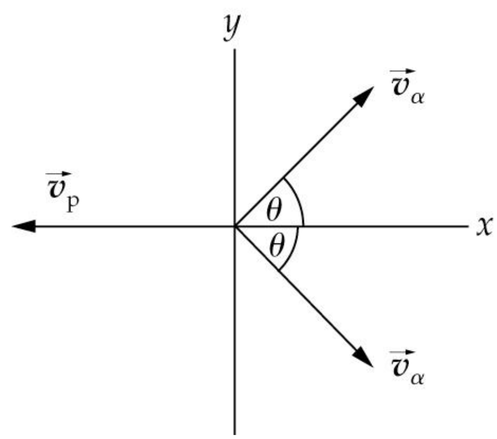
$$K_i = \tfrac{1}{2}m_3v_3^2 = \tfrac{1}{2}m_3(v_0\cos\theta)^2$$
$$= \tfrac{1}{2}(3\,\text{kg})\left[(120\,\text{m/s})\cos 30°\right]^2$$
$$= 16.2\,\text{kJ}$$

Substitute in equation (5) to determine the energy released in the explosion:

$$E_{exp} = K_f - K_i = 52.0\,\text{kJ} - 16.2\,\text{kJ}$$
$$= \boxed{35.8\,\text{kJ}}$$

***88** •••

Picture the Problem This nuclear reaction is $^9\text{B} \rightarrow 2\alpha + \text{p} + 4.4\times10^{-14}$ J. Assume that the proton moves in the –*x* direction as shown in the figure. The sum of the kinetic energies of the decay products equals the energy released in the decay. We'll use conservation of momentum to find the angle between the velocities of the proton and the alpha particles. Note that $v_\alpha = v_\alpha{}'$.



Express the energy released to the kinetic energies of the decay products:

$$K_p + 2K_\alpha = E_{rel}$$

or

$$\tfrac{1}{2}m_pv_p^2 + 2\left(\tfrac{1}{2}m_\alpha v_\alpha^2\right) = E_{rel}$$

Solve for v_α:

$$v_\alpha = \sqrt{\frac{E_{rel} - \tfrac{1}{2}m_pv_p^2}{m_\alpha}}$$

Substitute numerical values and evaluate v_α:

$$v_\alpha = \sqrt{\frac{4.4\times10^{-14}\text{ J}}{6.68\times10^{-27}\text{ kg}} - \frac{\frac{1}{2}\left(1.67\times10^{-27}\text{ kg}\right)\left(6\times10^{6}\text{ m/s}\right)^2}{6.68\times10^{-27}\text{ kg}}} = \boxed{1.44\times10^{6}\text{ m/s}}$$

Given that the boron isotope was at rest prior to the decay, use conservation of momentum to relate the momenta of the decay products:

$$\vec{p}_\text{f} = \vec{p}_\text{i} = 0 \Rightarrow p_{x\text{f}} = 0$$
$$\therefore 2\left(m_\alpha v_\alpha \cos\theta\right) - m_\text{p} v_\text{p} = 0$$
or
$$2\left(4m_\text{p} v_\alpha \cos\theta\right) - m_\text{p} v_\text{p} = 0$$

Solve for θ:

$$\theta = \cos^{-1}\left[\frac{v_\text{p}}{8v_\alpha}\right]$$
$$= \cos^{-1}\left[\frac{6\times10^{6}\text{ m/s}}{8\left(1.44\times10^{6}\text{ m/s}\right)}\right] = \pm58.7°$$

Let θ' equal the angle the velocities of the alpha particles make with that of the proton:

$$\theta' = \pm\left(180° - 58.7°\right)$$
$$= \boxed{\pm121°}$$

Coefficient of Restitution

89 •

Picture the Problem The coefficient of restitution is defined as the ratio of the velocity of recession to the velocity of approach. These velocities can be determined from the heights from which the ball was dropped and the height to which it rebounded by using conservation of mechanical energy.

Use its definition to relate the coefficient of restitution to the velocities of approach and recession:

$$e = \frac{v_\text{rec}}{v_\text{app}}$$

Letting $U_\text{g} = 0$ at the surface of the steel plate, apply conservation of energy to express the velocity of approach:

$$\Delta K + \Delta U = 0$$
Because $K_\text{i} = U_\text{f} = 0$,
$$K_\text{f} - U_\text{i} = 0$$
or
$$\tfrac{1}{2} m v_\text{app}^2 - mgh_\text{app} = 0$$

Solve for v_app:

$$v_\text{app} = \sqrt{2gh_\text{app}}$$

In like manner, show that: $v_{rec} = \sqrt{2gh_{rec}}$

Substitute in the equation for *e* to obtain:

$$e = \frac{\sqrt{2gh_{rec}}}{\sqrt{2gh_{app}}} = \sqrt{\frac{h_{rec}}{h_{app}}}$$

Substitute numerical values and evaluate *e*:

$$e = \sqrt{\frac{2.5\,\text{m}}{3\,\text{m}}} = \boxed{0.913}$$

***90** •

Picture the Problem The coefficient of restitution is defined as the ratio of the velocity of recession to the velocity of approach. These velocities can be determined from the heights from which an object was dropped and the height to which it rebounded by using conservation of mechanical energy.

Use its definition to relate the coefficient of restitution to the velocities of approach and recession:

$$e = \frac{v_{rec}}{v_{app}}$$

Letting $U_g = 0$ at the surface of the steel plate, apply conservation of energy to express the velocity of approach:

$$\Delta K + \Delta U = 0$$

Because $K_i = U_f = 0$,

$$K_f - U_i = 0$$

or

$$\tfrac{1}{2}mv_{app}^2 - mgh_{app} = 0$$

Solve for v_{app}:

$$v_{app} = \sqrt{2gh_{app}}$$

In like manner, show that:

$$v_{rec} = \sqrt{2gh_{rec}}$$

Substitute in the equation for *e* to obtain:

$$e = \frac{\sqrt{2gh_{rec}}}{\sqrt{2gh_{app}}} = \sqrt{\frac{h_{rec}}{h_{app}}}$$

Find e_{min}:

$$e_{min} = \sqrt{\frac{173\,\text{cm}}{254\,\text{cm}}} = 0.825$$

Find e_{max}:

$$e_{max} = \sqrt{\frac{183\,\text{cm}}{254\,\text{cm}}} = 0.849$$

and $\boxed{0.825 \le e \le 0.849}$

91 •

Picture the Problem Because the rebound kinetic energy is proportional to the rebound height, the percentage of mechanical energy lost in one bounce can be inferred from knowledge of the rebound height. The coefficient of restitution is defined as the ratio of the velocity of recession to the velocity of approach. These velocities can be determined from the heights from which an object was dropped and the height to which it rebounded by using conservation of mechanical energy.

(*a*) We know, from conservation of energy, that the kinetic energy of an object dropped from a given height *h* is proportional to *h*:

$K \propto h.$

If, for each bounce of the ball, $h_{rec} = 0.8h_{app}$:

$\boxed{20\% \text{ of its mechanical energy is lost.}}$

(*b*) Use its definition to relate the coefficient of restitution to the velocities of approach and recession:

$$e = \frac{v_{rec}}{v_{app}}$$

Letting $U_g = 0$ at the surface from which the ball is rebounding, apply conservation of energy to express the velocity of approach:

$$\Delta K + \Delta U = 0$$

Because $K_i = U_f = 0$,

$$K_f - U_i = 0$$

or

$$\tfrac{1}{2}mv_{app}^2 - mgh_{app} = 0$$

Solve for v_{app}:

$$v_{app} = \sqrt{2gh_{app}}$$

In like manner, show that:

$$v_{rec} = \sqrt{2gh_{rec}}$$

Substitute in the equation for *e* to obtain:

$$e = \frac{\sqrt{2gh_{rec}}}{\sqrt{2gh_{app}}} = \sqrt{\frac{h_{rec}}{h_{app}}}$$

Substitute for $\frac{h_{rec}}{h_{app}}$ to obtain:

$$e = \sqrt{0.8} = \boxed{0.894}$$

92 ••

Picture the Problem Let the numeral 2 refer to the 2-kg object and the numeral 4 to the 4-kg object. Choose a coordinate system in which the direction the 2-kg object is moving before the collision is the positive *x* direction and let the system consist of the earth, the surface on which the objects slide, and the objects. Then we can use conservation of momentum to find the velocity of the recoiling 4-kg object. We can find the energy transformed in the collision by calculating the difference between the kinetic energies before and after the collision and the coefficient of restitution from its definition.

(*a*) Use conservation of momentum in one dimension to relate the initial and final momenta of the participants in the collision:

$$\vec{\boldsymbol{p}}_\text{i} = \vec{\boldsymbol{p}}_\text{f}$$

or

$$m_2 v_{2\text{i}} = m_4 v_{4\text{f}} - m_2 v_{2\text{f}}$$

Solve for and evaluate the final velocity of the 4-kg object:

$$v_{4\text{f}} = \frac{m_2 v_{2\text{i}} + m_2 v_{2\text{f}}}{m_4} = \frac{(2\,\text{kg})(6\,\text{m/s} + 1\,\text{m/s})}{4\,\text{kg}} = \boxed{3.50\,\text{m/s}}$$

(*b*) Express the energy lost in terms of the kinetic energies before and after the collision:

$$\begin{aligned} E_\text{lost} &= K_\text{i} - K_\text{f} \\ &= \tfrac{1}{2} m_2 v_{2\text{i}}^2 - \left(\tfrac{1}{2} m_2 v_{2\text{f}}^2 + \tfrac{1}{2} m_4 v_{4\text{f}}^2\right) \\ &= \tfrac{1}{2}\left[m_2\left(v_{2\text{i}}^2 - v_{2\text{f}}^2\right) - m_4 v_{4\text{f}}^2\right] \end{aligned}$$

Substitute numerical values and evaluate E_lost:

$$E_\text{lost} = \tfrac{1}{2}\left[\left((2\,\text{kg})\left\{(6\,\text{m/s})^2 - (1\,\text{m/s})^2\right\}\right) - (4\,\text{kg})(3.5\,\text{m/s})^2\right] = \boxed{10.5\,\text{J}}$$

(*c*) Use the definition of the coefficient of restitution:

$$e = \frac{v_\text{rec}}{v_\text{app}} = \frac{v_{4\text{f}} - v_{2\text{f}}}{v_{2\text{i}}} = \frac{3.5\,\text{m/s} - (-1\,\text{m/s})}{6\,\text{m/s}} = \boxed{0.750}$$

93 ••

Picture the Problem Let the numeral 2 refer to the 2-kg block and the numeral 3 to the 3-kg block. Choose a coordinate system in which the direction the blocks are moving before the collision is the positive *x* direction and let the system consist of the earth, the surface on which the blocks move, and the blocks. Then we can use conservation of momentum find the velocity of the 2-kg block after the collision. We can find the coefficient of restitution from its definition.

(*a*) Use conservation of momentum in one dimension to relate the initial and final momenta of the participants in the collision:

$$\vec{p}_i = \vec{p}_f$$

or

$$m_2 v_{2i} + m_3 v_{3i} = m_2 v_{2f} + m_3 v_{3f}$$

Solve for the final velocity of the 2-kg object:

$$v_{2f} = \frac{m_2 v_{2i} + m_3 v_{3i} - m_3 v_{3f}}{m_2}$$

Substitute numerical values and evaluate v_{2f}:

$$v_{2f} = \frac{(2\,\text{kg})(5\,\text{m/s}) + (3\,\text{kg})(2\,\text{m/s} - 4.2\,\text{m/s})}{2\,\text{kg}} = \boxed{1.70\,\text{m/s}}$$

(*b*) Use the definition of the coefficient of restitution:

$$e = \frac{v_{rec}}{v_{app}} = \frac{v_{3f} - v_{2f}}{v_{2i} - v_{3i}} = \frac{4.2\,\text{m/s} - 1.7\,\text{m/s}}{5\,\text{m/s} - 2\,\text{m/s}}$$

$$= \boxed{0.833}$$

Collisions in Three Dimensions

***94 ••**

Picture the Problem We can use the definition of the magnitude of a vector and the definition of the dot product to establish the result called for in (*a*). In part (*b*) we can use the result of part (*a*), the conservation of momentum, and the definition of an elastic collision (kinetic energy is conserved) to show that the particles separate at right angles.

(*a*) Find the dot product of $\vec{B} + \vec{C}$ with itself:

$$\left(\vec{B} + \vec{C}\right) \cdot \left(\vec{B} + \vec{C}\right) = B^2 + C^2 + 2\vec{B} \cdot \vec{C}$$

Because $\vec{A} = \vec{B} + \vec{C}$:

$$A^2 = \left|\vec{B} + \vec{C}\right|^2 = \left(\vec{B} + \vec{C}\right) \cdot \left(\vec{B} + \vec{C}\right)$$

Substitute to obtain:

$$\boxed{A^2 = B^2 + C^2 + 2\vec{B} \cdot \vec{C}}$$

(*b*) Apply conservation of momentum to the collision of the particles:

$$\vec{p}_1 + \vec{p}_2 = \vec{P}$$

Form the dot product of each side of this equation with itself to obtain:

$$\left(\vec{p}_1 + \vec{p}_2\right) \cdot \left(\vec{p}_1 + \vec{p}_2\right) = \vec{P} \cdot \vec{P}$$

or

$$p_1^2 + p_2^2 + 2\vec{p}_1 \cdot \vec{p}_2 = P^2 \qquad (1)$$

Apply the definition of an elastic collision to obtain:

$$\frac{p_1^2}{2m} + \frac{p_2^2}{2m} = \frac{P^2}{2m}$$

or

$$p_1^2 + p_2^2 = P^2 \qquad (2)$$

Subtract equation (1) from equation (2) to obtain:

$$2\vec{p}_1 \cdot \vec{p}_2 = 0 \text{ or } \boxed{\vec{p}_1 \cdot \vec{p}_2 = 0}$$

i.e., the particles move apart along paths that are at right angles to each other.

95 •

Picture the Problem Let the initial direction of motion of the cue ball be the positive *x* direction. We can apply conservation of energy to determine the angle the cue ball makes with the positive *x* direction and the conservation of momentum to find the final velocities of the cue ball and the eight ball.

(*a*) Use conservation of energy to relate the velocities of the collision participants before and after the collision:

$$\tfrac{1}{2}mv_{\text{ci}}^2 = \tfrac{1}{2}mv_{\text{cf}}^2 + \tfrac{1}{2}mv_8^2$$

or

$$v_{\text{ci}}^2 = v_{\text{cf}}^2 + v_8^2$$

This Pythagorean relationship tells us that $\vec{v}_{\text{ci}}$, $\vec{v}_{\text{cf}}$, and $\vec{v}_8$ form a right triangle. Hence:

$$\theta_{\text{cf}} + \theta_8 = 90°$$

and

$$\theta_{\text{cf}} = \boxed{60°}$$

(*b*) Use conservation of momentum in the *x* direction to relate the velocities of the collision participants before and after the collision:

$$\vec{p}_{\text{xi}} = \vec{p}_{\text{xf}}$$

or

$$mv_{\text{ci}} = mv_{\text{cf}}\cos\theta_{\text{cf}} + mv_8\cos\theta_8$$

Use conservation of momentum in the *y* direction to obtain a second equation relating the velocities of the collision participants before and after the collision:

$$\vec{p}_{\text{yi}} = \vec{p}_{\text{yf}}$$

or

$$0 = mv_{\text{cf}}\sin\theta_{\text{cf}} + mv_8\sin\theta_8$$

Solve these equations simultaneously to obtain:

$$v_{\text{cf}} = \boxed{2.50\,\text{m/s}}$$

and

$$v_8 = \boxed{4.33\,\text{m/s}}$$

96 ••

Picture the Problem We can find the final velocity of the object whose mass is M_1 by using the conservation of momentum. Whether the collision was elastic can be decided by examining the difference between the initial and final kinetic energy of the interacting objects.

(*a*) Use conservation of momentum to relate the initial and final velocities of the two objects:

$$\vec{p}_i = \vec{p}_f$$

or

$$mv_0\hat{i} + 2m\left(\tfrac{1}{2}v_0\hat{j}\right) = 2m\left(\tfrac{1}{4}v_0\hat{i}\right) + m\vec{v}_{1f}$$

Simplify to obtain:

$$v_0\hat{i} + v_0\hat{j} = \tfrac{1}{2}v_0\hat{i} + \vec{v}_{1f}$$

Solve for $\vec{v}_{1f}$:

$$\vec{v}_{1f} = \boxed{\tfrac{1}{2}v_0\hat{i} + v_0\hat{j}}$$

(*b*) Express the difference between the kinetic energy of the system before the collision and its kinetic energy after the collision:

$$\begin{aligned}\Delta E &= K_i - K_f = K_{1i} + K_{2i} - (K_{1f} + K_{2f}) = \tfrac{1}{2}\left[M_1v_{1i}^2 + M_2v_{2i}^2 - M_1v_{1f}^2 - M_2v_{2f}^2\right] \\ &= \tfrac{1}{2}\left[mv_{1i}^2 + 2mv_{2i}^2 - mv_{1f}^2 - 2mv_{2f}^2\right] = \tfrac{1}{2}m\left[v_{1i}^2 + 2v_{2i}^2 - v_{1f}^2 - 2v_{2f}^2\right] \\ &= \tfrac{1}{2}m\left[v_0^2 + 2\left(\tfrac{1}{4}v_0^2\right) - \tfrac{5}{4}v_0^2 - 2\left(\tfrac{1}{16}v_0^2\right)\right] = \boxed{\tfrac{1}{16}mv_0^2}\end{aligned}$$

$$\boxed{\text{Because } \Delta E \neq 0 \text{, the collision is } \textit{inelastic}.}$$

***97** ••

Picture the Problem Let the direction of motion of the puck that is moving before the collision be the positive *x* direction. Applying conservation of momentum to the collision in both the *x* and *y* directions will lead us to two equations in the unknowns v_1 and v_2 that we can solve simultaneously. We can decide whether the collision was elastic by either calculating the system's kinetic energy before and after the collision or by determining whether the angle between the final velocities is 90°.

(*a*) Use conservation of momentum in the *x* direction to relate the velocities of the collision participants before and after the collision:

$$p_{xi} = p_{xf}$$

or

$$mv = mv_1\cos 30° + mv_2\cos 60°$$

or

$$v = v_1\cos 30° + v_2\cos 60°$$

Use conservation of momentum in the y direction to obtain a second equation relating the velocities of the collision participants before and after the collision:

$$p_{yi} = p_{yf}$$

or

$$0 = mv_1 \sin 30° - mv_2 \sin 60°$$

or

$$0 = v_1 \sin 30° - v_2 \sin 60°$$

Solve these equations simultaneously to obtain:

$$v_1 = \boxed{1.73\,\text{m/s}} \text{ and } v_2 = \boxed{1.00\,\text{m/s}}$$

(*b*) $\boxed{\text{Because the angle between } \vec{v}_1 \text{ and } \vec{v}_2 \text{ is } 90°\text{, the collision was } \textit{elastic}.}$

98 ••

Picture the Problem Let the direction of motion of the object that is moving before the collision be the positive x direction. Applying conservation of momentum to the motion in both the x and y directions will lead us to two equations in the unknowns v_2 and θ_2 that we can solve simultaneously. We can show that the collision was elastic by showing that the system's kinetic energy before and after the collision is the same.

(*a*) Use conservation of momentum in the x direction to relate the velocities of the collision participants before and after the collision:

$$p_{xi} = p_{xf}$$

or

$$3mv_0 = \sqrt{5}mv_0 \cos\theta_1 + 2mv_2 \cos\theta_2$$

or

$$3v_0 = \sqrt{5}v_0 \cos\theta_1 + 2v_2 \cos\theta_2$$

Use conservation of momentum in the y direction to obtain a second equation relating the velocities of the collision participants before and after the collision:

$$p_{yi} = p_{yf}$$

or

$$0 = \sqrt{5}mv_0 \sin\theta_1 - 2mv_2 \sin\theta_2$$

or

$$0 = \sqrt{5}v_0 \sin\theta_1 - 2v_2 \sin\theta_2$$

Note that if $\tan\theta_1 = 2$, then:

$$\cos\theta_1 = \frac{1}{\sqrt{5}} \text{ and } \sin\theta_1 = \frac{2}{\sqrt{5}}$$

Substitute in the momentum equations to obtain:

$$3v_0 = \sqrt{5}v_0 \frac{1}{\sqrt{5}} + 2v_2 \cos\theta_2$$

or

$$v_0 = v_2 \cos\theta_2$$

and

$$0 = \sqrt{5}v_0 \frac{2}{\sqrt{5}} - 2v_2 \sin\theta_2$$

or

$$0 = v_0 - v_2 \sin\theta_2$$

Solve these equations simultaneously for θ_2:

$$\theta_2 = \tan^{-1}1 = \boxed{45.0°}$$

Substitute to find v_2:

$$v_2 = \frac{v_0}{\cos\theta_2} = \frac{v_0}{\cos 45°} = \boxed{\sqrt{2}v_0}$$

(*b*) To show that the collision was elastic, find the before-collision and after-collision kinetic energies:

$$K_\text{i} = \tfrac{1}{2}m(3v_0)^2 = 4.5mv_0^2$$

and

$$K_\text{f} = \tfrac{1}{2}m\left(\sqrt{5}v_0\right)^2 + \tfrac{1}{2}(2m)\left(\sqrt{2}v_0\right)^2 = 4.5mv_0^2$$

$$\boxed{\text{Because } K_\text{i} = K_\text{f}, \text{ the collision is elastic.}}$$

***99** ••

Picture the Problem Let the direction of motion of the ball that is moving before the collision be the positive *x* direction. Let *v* represent the velocity of the ball that is moving before the collision, v_1 its velocity after the collision and v_2 the velocity of the initially-at-rest ball after the collision. We know that because the collision is elastic and the balls have the same mass, v_1 and v_2 are 90° apart. Applying conservation of momentum to the collision in both the *x* and *y* directions will lead us to two equations in the unknowns v_1 and v_2 that we can solve simultaneously.

Noting that the angle of deflection for the recoiling ball is 60°, use conservation of momentum in the *x* direction to relate the velocities of the collision participants before and after the collision:

$$p_\text{xi} = p_\text{xf}$$

or

$$mv = mv_1 \cos 30° + mv_2 \cos 60°$$

or

$$v = v_1 \cos 30° + v_2 \cos 60°$$

Use conservation of momentum in the *y* direction to obtain a second equation relating the velocities of the collision participants before and after the collision:

$$p_\text{yi} = p_\text{yf}$$

or

$$0 = mv_1 \sin 30° - mv_2 \sin 60°$$

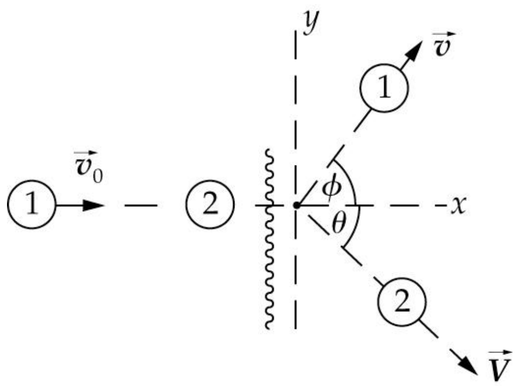
or

$$0 = v_1 \sin 30° - v_2 \sin 60°$$

Solve these equations simultaneously to obtain: $v_1 = \boxed{8.66\,\text{m/s}}$ and $v_2 = \boxed{5.00\,\text{m/s}}$

100 ••

Picture the Problem Choose the coordinate system shown in the diagram below with the *x*-axis the axis of initial approach of the first particle. Call *V* the speed of the target particle after the collision. In part (*a*) we can apply conservation of momentum in the *x* and *y* directions to obtain two equations that we can solve simultaneously for tan*θ*. In part (*b*) we can use conservation of momentum in vector form and the elastic-collision equation to show that $v = v_0\cos\phi$.



(*a*) Apply conservation of momentum in the *x* direction to obtain:

$$v_0 = v\cos\phi + V\cos\theta \quad (1)$$

Apply conservation of momentum in the *y* direction to obtain:

$$v\sin\phi = V\sin\theta \quad (2)$$

Solve equation (1) for $V\cos\theta$:

$$V\cos\theta = v_0 - v\cos\phi \quad (3)$$

Divide equation (2) by equation (3) to obtain:

$$\frac{V\sin\theta}{V\cos\theta} = \frac{v\sin\phi}{v_0 - v\cos\phi}$$

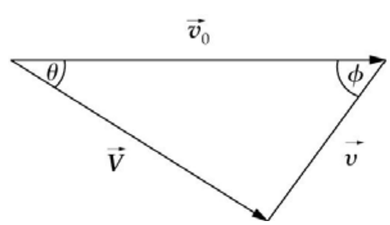
or

$$\tan\theta = \boxed{\frac{v\sin\phi}{v_0 - v\cos\phi}}$$

(*b*) Apply conservation of momentum to obtain:

$$\vec{v}_0 = \vec{v} + \vec{V}$$

Draw the vector diagram representing this equation:



Use the definition of an elastic

$$v_0^2 = v^2 + V^2$$

collision to obtain:

If this Pythagorean condition is to hold, the third angle of the triangle must be a right angle and, using the definition of the cosine function:

$$v = \boxed{v_0 \cos\phi}$$

Center-of-Mass Frame

101 ••

Picture the Problem The total kinetic energy of a system of particles is the sum of the kinetic energy of the center of mass and the kinetic energy relative to the center of mass. The kinetic energy of a particle of mass m is related to momentum according to $K = p^2/2m$.

Express the total kinetic energy of the system:

$$K = K_{\text{rel}} + K_{\text{cm}} \qquad (1)$$

Relate the kinetic energy relative to the center of mass to the momenta of the two particles:

$$K_{\text{rel}} = \frac{p_1^2}{2m_1} + \frac{p_1^2}{2m_2} = \frac{p_1^2(m_1 + m_2)}{2m_1m_2}$$

Express the kinetic energy of the center of mass of the two particles:

$$K_{\text{cm}} = \frac{(2p_1)^2}{2(m_1 + m_2)} = \frac{2p_1^2}{m_1 + m_2}$$

Substitute in equation (1) and simplify to obtain:

$$K = \frac{p_1^2(m_1 + m_2)}{2m_1m_2} + \frac{2p_1^2}{m_1 + m_2}$$

$$= \frac{p_1^2}{2}\left[\frac{m_1^2 + 6m_1m_2 + m_2^2}{m_1^2m_2 + m_1m_2^2}\right]$$

In an elastic collision:

$$K_{\text{i}} = K_{\text{f}}$$

$$= \boxed{\frac{p_1^2}{2}\left[\frac{m_1^2 + 6m_1m_2 + m_2^2}{m_1^2m_2 + m_1m_2^2}\right]}$$

$$= \boxed{\frac{p_1'^2}{2}\left[\frac{m_1^2 + 6m_1m_2 + m_2^2}{m_1^2m_2 + m_1m_2^2}\right]}$$

Simplify to obtain:

$$(p_1')^2 = (p_1)^2 \Rightarrow \boxed{p_1' = \pm p_1}$$

and

$$\boxed{\text{If } p_1' = +p_1, \text{the particles do not collide.}}$$

***102** ••

Picture the Problem Let the numerals 3 and 1 denote the blocks whose masses are 3 kg and 1 kg respectively. We can use $\sum_i m_i\vec{v}_i = M\vec{v}_{\rm cm}$ to find the velocity of the center-of-mass of the system and simply follow the directions in the problem step by step.

(*a*) Express the total momentum of this two-particle system in terms of the velocity of its center of mass:

$$\vec{P} = \sum_i m_i\vec{v}_i = m_1\vec{v}_1 + m_3\vec{v}_3 = M\vec{v}_{\rm cm} = (m_1 + m_3)\vec{v}_{\rm cm}$$

Solve for $\vec{v}_{\rm cm}$:

$$\vec{v}_{\rm cm} = \frac{m_3\vec{v}_3 + m_1\vec{v}_1}{m_3 + m_1}$$

Substitute numerical values and evaluate $\vec{v}_{\rm cm}$:

$$\vec{v}_{\rm cm} = \frac{(3\,\text{kg})(-5\,\text{m/s})\hat{i} + (1\,\text{kg})(3\,\text{m/s})\hat{i}}{3\,\text{kg} + 1\,\text{kg}} = \boxed{(-3.00\,\text{m/s})\hat{i}}$$

(*b*) Find the velocity of the 3-kg block in the center of mass reference frame:

$$\vec{u}_3 = \vec{v}_3 - \vec{v}_{\rm cm} = (-5\,\text{m/s})\hat{i} - (-3\,\text{m/s})\hat{i} = \boxed{(-2.00\,\text{m/s})\hat{i}}$$

Find the velocity of the 1-kg block in the center of mass reference frame:

$$\vec{u}_1 = \vec{v}_1 - \vec{v}_{\rm cm} = (3\,\text{m/s})\hat{i} - (-3\,\text{m/s})\hat{i} = \boxed{(6.00\,\text{m/s})\hat{i}}$$

(*c*) Express the after-collision velocities of both blocks in the center of mass reference frame:

$$\vec{u}_3' = \boxed{(2.00\,\text{m/s})\hat{i}}$$

and

$$\vec{u}_1' = \boxed{(-6.00\,\text{m/s})\hat{i}}$$

(*d*) Transform the after-collision velocity of the 3-kg block from the center of mass reference frame to the original reference frame:

$$\vec{v}_3' = \vec{u}_3' + \vec{v}_{\rm cm} = (2\,\text{m/s})\hat{i} + (-3\,\text{m/s})\hat{i} = \boxed{(-1.00\,\text{m/s})\hat{i}}$$

Transform the after-collision velocity of the 1-kg block from the center of mass reference frame to the original reference frame:

$$\vec{v}_1' = \vec{u}_1' + \vec{v}_{\rm cm} = (-6\,\text{m/s})\hat{i} + (-3\,\text{m/s})\hat{i} = \boxed{(-9.00\,\text{m/s})\hat{i}}$$

(*e*) Express $K_{\rm i}$ in the original frame of

$$K_{\rm i} = \tfrac{1}{2}m_3v_3^2 + \tfrac{1}{2}m_1v_1^2$$

reference:

Substitute numerical values and evaluate K_i:

$$K_i = \tfrac{1}{2}\left[(3\,\text{kg})(5\,\text{m/s})^2 + (1\,\text{kg})(3\,\text{m/s})^2\right] = \boxed{42.0\,\text{J}}$$

Express K_f in the original frame of reference:

$$K_f = \tfrac{1}{2}m_3 v_3'^2 + \tfrac{1}{2}m_1 v_1'^2$$

Substitute numerical values and evaluate K_f:

$$K_f = \tfrac{1}{2}\left[(3\,\text{kg})(1\,\text{m/s})^2 + (1\,\text{kg})(9\,\text{m/s})^2\right] = \boxed{42.0\,\text{J}}$$

103 ••

Picture the Problem Let the numerals 3 and 1 denote the blocks whose masses are 3 kg and 1 kg respectively. We can use $\sum_i m_i \vec{v}_i = M\vec{v}_{cm}$ to find the velocity of the center-of-mass of the system and simply follow the directions in the problem step by step.

(*a*) Express the total momentum of this two-particle system in terms of the velocity of its center of mass:

$$\vec{P} = \sum_i m_i \vec{v}_i = m_3\vec{v}_3 + m_5\vec{v}_5 = M\vec{v}_{cm} = (m_3 + m_5)\vec{v}_{cm}$$

Solve for $\vec{v}_{cm}$:

$$\vec{v}_{cm} = \frac{m_3\vec{v}_3 + m_5\vec{v}_5}{m_3 + m_5}$$

Substitute numerical values and evaluate $\vec{v}_{cm}$:

$$\vec{v}_{cm} = \frac{(3\,\text{kg})(-5\,\text{m/s})\hat{\boldsymbol{i}} + (5\,\text{kg})(3\,\text{m/s})\hat{\boldsymbol{i}}}{3\,\text{kg} + 5\,\text{kg}} = \boxed{0}$$

(*b*) Find the velocity of the 3-kg block in the center of mass reference frame:

$$\vec{u}_3 = \vec{v}_3 - \vec{v}_{cm} = (-5\,\text{m/s})\,\hat{\boldsymbol{i}} - 0 = \boxed{(-5\,\text{m/s})\,\hat{\boldsymbol{i}}}$$

Find the velocity of the 5-kg block in the center of mass reference frame:

$$\vec{u}_5 = \vec{v}_5 - \vec{v}_{cm} = (3\,\text{m/s})\hat{\boldsymbol{i}} - 0 = \boxed{(3\,\text{m/s})\hat{\boldsymbol{i}}}$$

(*c*) Express the after-collision velocities of both blocks in the center of mass reference frame:

$$\vec{u}_3' = \boxed{(5\,\text{m/s})\hat{\boldsymbol{i}}}$$

and

$$u_5' = \boxed{0.75\,\text{m/s}}$$

(*d*) Transform the after-collision velocity of the 3-kg block from the center of mass reference frame to the original reference frame:

$$\vec{v}_3' = \vec{u}_3' + \vec{v}_{cm} = (5\,\text{m/s})\hat{i} + 0 = \boxed{(5\,\text{m/s})\hat{i}}$$

Transform the after-collision velocity of the 5-kg block from the center of mass reference frame to the original reference frame:

$$\vec{v}_5' = \vec{u}_5' + \vec{v}_{cm} = (-3\,\text{m/s})\hat{i} + 0 = \boxed{(-3\,\text{m/s})\hat{i}}$$

(*e*) Express K_i in the original frame of reference:

$$K_i = \tfrac{1}{2}m_3v_3^2 + \tfrac{1}{2}m_5v_5^2$$

Substitute numerical values and evaluate K_i:

$$K_i = \tfrac{1}{2}\left[(3\,\text{kg})(5\,\text{m/s})^2 + (5\,\text{kg})(3\,\text{m/s})^2\right] = \boxed{60.0\,\text{J}}$$

Express K_f in the original frame of reference:

$$K_f = \tfrac{1}{2}m_3v_3'^2 + \tfrac{1}{2}m_5v_5'^2$$

Substitute numerical values and evaluate K_f:

$$K_f = \tfrac{1}{2}\left[(3\,\text{kg})(5\,\text{m/s})^2 + (5\,\text{kg})(3\,\text{m/s})^2\right] = \boxed{60.0\,\text{J}}$$

Systems With Continuously Varying Mass: Rocket Propulsion

104 ••

Picture the Problem The thrust of a rocket F_{th} depends on the burn rate of its fuel *dm/dt* and the relative speed of its exhaust gases u_{ex} according to $F_{th} = |dm/dt|u_{ex}$.

Using its definition, relate the rocket's thrust to the relative speed of its exhaust gases:

$$F_{th} = \left|\frac{dm}{dt}\right|u_{ex}$$

Substitute numerical values and evaluate F_{th}:

$$F_{th} = (200\,\text{kg/s})(6\,\text{km/s}) = \boxed{1.20\,\text{MN}}$$

105 ••

Picture the Problem The thrust of a rocket F_{th} depends on the burn rate of its fuel dm/dt and the relative speed of its exhaust gases u_{ex} according to $F_{th} = |dm/dt|u_{ex}$. The final velocity v_f of a rocket depends on the relative speed of its exhaust gases u_{ex}, its payload to initial mass ratio m_f/m_0 and its burn time according to $v_f = -u_{ex}\ln(m_f/m_0) - gt_b$.

(*a*) Using its definition, relate the rocket's thrust to the relative speed of its exhaust gases:

$$F_{th} = \left|\frac{dm}{dt}\right|u_{ex}$$

Substitute numerical values and evaluate F_{th}:

$$F_{th} = (200\,\text{kg/s})(1.8\,\text{km/s}) = \boxed{360\,\text{kN}}$$

(*b*) Relate the time to burnout to the mass of the fuel and its burn rate:

$$t_b = \frac{m_{fuel}}{dm/dt} = \frac{0.8m_0}{dm/dt}$$

Substitute numerical values and evaluate t_b:

$$t_b = \frac{0.8(30{,}000\,\text{kg})}{200\,\text{kg/s}} = \boxed{120\,\text{s}}$$

(*c*) Relate the final velocity of a rocket to its initial mass, exhaust velocity, and burn time:

$$v_f = -u_{ex}\ln\left(\frac{m_f}{m_0}\right) - gt_b$$

Substitute numerical values and evaluate v_f:

$$v_f = -(1.8\,\text{km/s})\ln\left(\frac{1}{5}\right) - (9.81\,\text{m/s}^2)(120\,\text{s}) = \boxed{1.72\,\text{km/s}}$$

***106** ••

Picture the Problem We can use the dimensions of thrust, burn rate, and acceleration to show that the dimension of specific impulse is time. Combining the definitions of rocket thrust and specific impulse will lead us to $u_{ex} = gI_{sp}$.

(*a*) Express the dimension of specific impulse in terms of the dimensions of F_{th}, R, and g:

$$[I_{sp}] = \frac{[F_{th}]}{[R][g]} = \frac{\frac{\text{M}\cdot\text{L}}{\text{T}^2}}{\frac{\text{M}}{\text{T}}\cdot\frac{\text{L}}{\text{T}^2}} = \boxed{\text{T}}$$

(*b*) From the definition of rocket thrust we have:

$$F_{th} = Ru_{ex}$$

Solve for u_{ex}:

$$u_{ex} = \frac{F_{th}}{R}$$

Substitute for F_{th} to obtain:

$$u_{ex} = \frac{RgI_{sp}}{R} = \boxed{gI_{sp}} \qquad (1)$$

(*c*) Solve equation (1) for I_{sp} and substitute for u_{ex} to obtain:

$$I_{sp} = \frac{F_{th}}{Rg}$$

From Example 8-21 we have:

$R = 1.384\times10^4$ kg/s and $F_{th} = 3.4\times10^6$ N

Substitute numerical values and evaluate I_{sp}:

$$I_{sp} = \frac{3.4\times10^6\ \text{N}}{(1.384\times10^4\ \text{kg/s})(9.81\ \text{m/s}^2)} = \boxed{25.0\ \text{s}}$$

***107 •••**

Picture the Problem We can use the rocket equation and the definition of rocket thrust to show that $\tau_0 = 1 + a_0/g$. In part (*b*) we can express the burn time t_b in terms of the initial and final masses of the rocket and the rate at which the fuel burns, and then use this equation to express the rocket's final velocity in terms of I_{sp}, τ_0, and the mass ratio m_0/m_f. In part (*d*) we'll need to use trial-and-error methods or a graphing calculator to solve the transcendental equation giving v_f as a function of m_0/m_f.

(*a*) Express the rocket equation:

$$-mg + Ru_{ex} = ma$$

From the definition of rocket thrust we have:

$$F_{th} = Ru_{ex}$$

Substitute to obtain:

$$-mg + F_{th} = ma$$

Solve for F_{th} at takeoff:

$$F_{th} = m_0 g + m_0 a_0$$

Divide both sides of this equation by $m_0 g$ to obtain:

$$\frac{F_{th}}{m_0 g} = 1 + \frac{a_0}{g}$$

Because $\tau_0 = F_{th}/(m_0 g)$:

$$\tau_0 = \boxed{1 + \frac{a_0}{g}}$$

(*b*) Use equation 8-42 to express the final speed of a rocket that starts from rest with mass m_0:

$$v_f = u_{ex}\ln\frac{m_0}{m_f} - gt_b, \qquad (1)$$

where t_b is the burn time.

Express the burn time in terms of the burn rate R (assumed constant):

$$t_b = \frac{m_0 - m_f}{R} = \frac{m_0}{R}\left(1 - \frac{m_f}{m_0}\right)$$

Multiply t_b by one in the form gT/gT and simplify to obtain:

$$t_b = \frac{gF_{th}}{gF_{th}} \frac{m_0}{R}\left(1-\frac{m_f}{m_0}\right) = \frac{gm_0}{F_{th}} \frac{F_{th}}{gR}\left(1-\frac{m_f}{m_0}\right) = \frac{I_{sp}}{\tau_0}\left(1-\frac{m_f}{m_0}\right)$$

Substitute in equation (1):

$$v_f = u_{ex} \ln \frac{m_0}{m_f} - \frac{gI_{sp}}{\tau_0}\left(1-\frac{m_f}{m_0}\right)$$

From Problem 32 we have:

$$u_{ex} = gI_{sp},$$

where u_{ex} is the exhaust velocity of the propellant.

Substitute and factor to obtain:

$$v_f = gI_{sp} \ln \frac{m_0}{m_f} - \frac{gI_{sp}}{\tau_0}\left(1-\frac{m_f}{m_0}\right) = \boxed{gI_{sp}\left[\ln\left(\frac{m_0}{m_f}\right) - \frac{1}{\tau_0}\left(1-\frac{m_f}{m_0}\right)\right]}$$

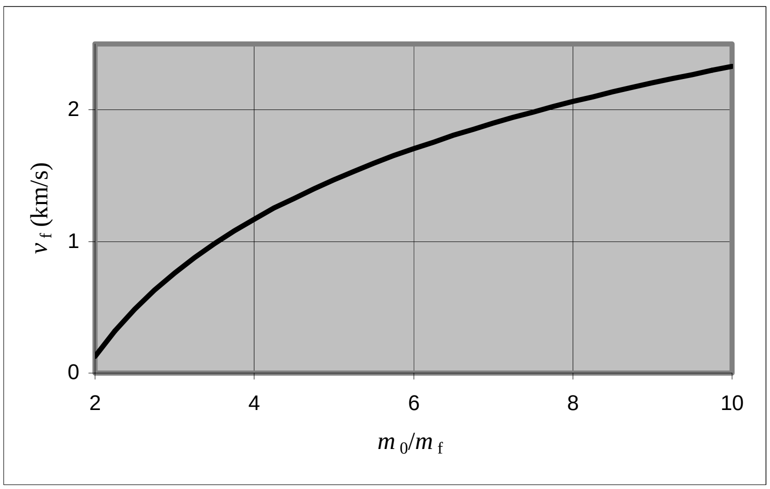
(*c*) A spreadsheet program to calculate the final velocity of the rocket as a function of the mass ratio m_0/m_f is shown below. The constants used in the velocity function and the formulas used to calculate the final velocity are as follows:

Cell	Content/Formula	Algebraic Form
B1	250	I_{sp}
B2	9.81	g
B3	2	τ
D9	D8 + 0.25	m_0/m_f
E8	\$B\$2*\$B\$1*(LOG(D8) – (1/\$B\$3)*(1/D8))	$gI_{sp}\left[\ln\left(\frac{m_0}{m_f}\right) - \frac{1}{\tau_0}\left(1-\frac{m_f}{m_0}\right)\right]$

	A	B	C	D	E
1	Isp =	250	s		
2	g =	9.81	m/s^2		
3	tau =	2			
4					
5					
6					
7				mass ratio	vf
8				2.00	1.252E+02
9				2.25	3.187E+02

10				2.50	4.854E+02
11				2.75	6.316E+02
12				3.00	7.614E+02
36				9.00	2.204E+03
37				9.25	2.237E+03
38				9.50	2.269E+03
39				9.75	2.300E+03
40				10.00	2.330E+03
41				725.00	7.013E+03

A graph of final velocity as a function of mass ratio is shown below.



(d) Substitute the data given in part (c) in the equation derived in part (b) to obtain:

$$7\,\text{km/s} = \left(9.81\,\text{m/s}^2\right)\left(250\,\text{s}\right)\left(\ln\frac{m_0}{m_\text{f}} - \frac{1}{2}\left(1 - \frac{m_\text{f}}{m_0}\right)\right)$$

or

$$2.854 = \ln x - 0.5 + \frac{0.5}{x} \text{ where } x = m_0/m_\text{f}.$$

Use trial-and-error methods or a graphing calculator to solve this transcendental equation for the root greater than 1:

$$x = \boxed{28.1},$$

a value considerably larger than the practical limit of 10 for single-stage rockets.

108 ••

Picture the Problem We can use the velocity-at-burnout equation from Problem 106 to find v_f and constant-acceleration equations to approximate the maximum height the rocket will reach and its total flight time.

(a) Assuming constant acceleration, relate the maximum height reached

$$h = \tfrac{1}{2} g t_\text{top}^2 \qquad (1)$$

by the model rocket to its time-to-top-of-trajectory:

From Problem 106 we have:

$$v_f = gI_{sp}\left(\ln\left(\frac{m_0}{m_f}\right) - \frac{1}{\tau}\left(1 - \frac{m_f}{m_0}\right)\right)$$

Evaluate the velocity at burnout v_f for I_{sp} = 100 s, m_0/m_f = 1.2, and τ = 5:

$$v_f = \left(9.81\,\text{m/s}^2\right)\left(100\,\text{s}\right) \times\left[\ln(1.2) - \frac{1}{5}\left(1 - \frac{1}{1.2}\right)\right] = 146\,\text{m/s}$$

Assuming that the time for the fuel to burn up is short compared to the total flight time, find the time to the top of the trajectory:

$$t_{top} = \frac{v_f}{g} = \frac{146\,\text{m/s}}{9.81\,\text{m/s}^2} = 14.9\,\text{s}$$

Substitute in equation (1) and evaluate h:

$$h = \tfrac{1}{2}\left(9.81\,\text{m/s}^2\right)\left(14.9\,\text{s}\right)^2 = \boxed{1.09\,\text{km}}$$

(*b*) Find the total flight time from the time it took the rocket to reach its maximum height:

$$t_{flight} = 2t_{top} = 2(14.9\,\text{s}) = \boxed{29.8\,\text{s}}$$

(*c*) Express and evaluate the fuel burn time t_b:

$$t_b = \frac{I_{sp}}{\tau}\left(1 - \frac{m_f}{m_0}\right) = \frac{100\,\text{s}}{5}\left(1 - \frac{1}{1.2}\right) = 3.33\,\text{s}$$

Because this burn time is approximately 1/5 of the total flight time, we can't expect the answer we obtained in Part (*b*) to be very accurate. It should, however, be good to about 30% accuracy, as the maximum distance the model rocket could possibly move in this time is $\frac{1}{2}vt_b = 243\,\text{m}$, assuming constant acceleration until burnout.

General Problems

109 •

Picture the Problem Let the direction of motion of the 250-g car before the collision be the positive *x* direction. Let the numeral 1 refer to the 250-kg car, the numeral 2 refer to the 400-kg car, and *V* represent the velocity of the linked cars. Let the system include the earth and the cars. We can use conservation of momentum to find their speed after they have linked together and the definition of kinetic energy to find their initial and final kinetic energies.

Use conservation of momentum to relate the speeds of the cars immediately before and immediately after their collision:

$$p_{ix} = p_{fx}$$
or
$$m_1v_1 = (m_1 + m_2)V$$

Solve for V:

$$V = \frac{m_1v_1}{m_1 + m_2}$$

Substitute numerical values and evaluate V:

$$V = \frac{(0.250\,\text{kg})(0.50\,\text{m/s})}{0.250\,\text{kg} + 0.400\,\text{kg}} = \boxed{0.192\,\text{m/s}}$$

Find the initial kinetic energy of the cars:

$$K_i = \tfrac{1}{2}m_1v_1^2 = \tfrac{1}{2}(0.250\,\text{kg})(0.50\,\text{m/s})^2 = \boxed{31.3\,\text{mJ}}$$

Find the final kinetic energy of the coupled cars:

$$K_f = \tfrac{1}{2}(m_1 + m_2)V^2 = \tfrac{1}{2}(0.250\,\text{kg} + 0.400\,\text{kg})(0.192\,\text{m/s})^2 = \boxed{12.0\,\text{mJ}}$$

110 •

Picture the Problem Let the direction of motion of the 250-g car before the collision be the positive x direction. Let the numeral 1 refer to the 250-kg car and the numeral 2 refer to the 400-g car and the system include the earth and the cars. We can use conservation of momentum to find their speed after they have linked together and the definition of kinetic energy to find their initial and final kinetic energies.

(*a*) Express and evaluate the initial kinetic energy of the cars:

$$K_i = \tfrac{1}{2}m_1v_1^2 = \tfrac{1}{2}(0.250\,\text{kg})(0.50\,\text{m/s})^2 = \boxed{31.3\,\text{mJ}}$$

(*b*) Relate the velocity of the center of mass to the total momentum of the system:

$$\vec{\boldsymbol{P}} = \sum_i m_i\vec{\boldsymbol{v}}_i = m\vec{\boldsymbol{v}}_{cm}$$

Solve for v_{cm}:

$$v_{cm} = \frac{m_1v_1 + m_2v_2}{m_1 + m_2}$$

Substitute numerical values and evaluate v_{cm}:

$$v_{cm} = \frac{(0.250\,\text{kg})(0.50\,\text{m/s})}{0.250\,\text{kg} + 0.400\,\text{kg}} = 0.192\,\text{m/s}$$

Find the initial velocity of the 250-g car relative to the velocity of the center of mass:

$$u_1 = v_1 - v_{cm} = 0.50\,\text{m/s} - 0.192\,\text{m/s}$$
$$= \boxed{0.308\,\text{m/s}}$$

Find the initial velocity of the 400-g car relative to the velocity of the center of mass:

$$u_2 = v_2 - v_{cm} = 0\,\text{m/s} - 0.192\,\text{m/s}$$
$$= \boxed{-0.192\,\text{m/s}}$$

Express the initial kinetic energy of the system relative to the center of mass:

$$K_{i,rel} = \tfrac{1}{2} m_1 u_1^2 + \tfrac{1}{2} m_2 u_2^2$$

Substitute numerical values and evaluate $K_{i,rel}$:

$$K_{i,rel} = \tfrac{1}{2}(0.250\,\text{kg})(0.308\,\text{m/s})^2$$
$$+ \tfrac{1}{2}(0.400\,\text{kg})(-0.192\,\text{m/s})^2$$
$$= \boxed{19.2\,\text{mJ}}$$

(*c*) Express the kinetic energy of the center of mass:

$$K_{cm} = \tfrac{1}{2} M v_{cm}^2$$

Substitute numerical values and evaluate K_{cm}:

$$K_{cm} = \tfrac{1}{2}(0.650\,\text{kg})(0.192\,\text{m/s})^2$$
$$= \boxed{12.0\,\text{mJ}}$$

(*d*) Relate the initial kinetic energy of the system to its initial kinetic energy relative to the center of mass and the kinetic energy of the center of mass:

$$K_i = K_{i,rel} + K_{cm}$$
$$= 19.2\,\text{mJ} + 12.0\,\text{mJ}$$
$$= 31.2\,\text{mJ}$$

$$\therefore \boxed{K_i = K_{i,rel} + K_{cm}}$$

***111** •

Picture the Problem Let the direction the 4-kg fish is swimming be the positive *x* direction and the system include the fish, the water, and the earth. The velocity of the larger fish immediately after its lunch is the velocity of the center of mass in this perfectly inelastic collision.

Relate the velocity of the center of mass to the total momentum of the system:

$$\vec{P} = \sum_i m_i \vec{v}_i = m\vec{v}_{cm}$$

Solve for v_{cm}:

$$v_{cm} = \frac{m_4 v_4 - m_{1.2} v_{1.2}}{m_4 + m_{1.2}}$$

Substitute numerical values and evaluate v_{cm}:

$$v_{cm} = \frac{(4\,\text{kg})(1.5\,\text{m/s}) - (1.2\,\text{kg})(3\,\text{m/s})}{4\,\text{kg} + 1.2\,\text{kg}} = \boxed{0.462\,\text{m/s}}$$

112 •

Picture the Problem Let the direction the 3-kg block is moving be the positive x direction and include both blocks and the earth in the system. The total kinetic energy of the two-block system is the sum of the kinetic energies of the blocks. We can relate the momentum of the system to the velocity of its center of mass and use this relationship to find v_{cm}. Finally, we can use the definition of kinetic energy to find the kinetic energy relative to the center of mass.

(*a*) Express the total kinetic energy of the system in terms of the kinetic energy of the blocks:

$$K_{tot} = \tfrac{1}{2} m_3 v_3^2 + \tfrac{1}{2} m_6 v_6^2$$

Substitute numerical values and evaluate K_{tot}:

$$K_{tot} = \tfrac{1}{2}(3\,\text{kg})(6\,\text{m/s})^2 + \tfrac{1}{2}(6\,\text{kg})(3\,\text{m/s})^2 = \boxed{81.0\,\text{J}}$$

(*b*) Relate the velocity of the center of mass to the total momentum of the system:

$$\vec{\boldsymbol{P}} = \sum_i m_i \vec{\boldsymbol{v}}_i = m\vec{\boldsymbol{v}}_{cm}$$

Solve for v_{cm}:

$$v_{cm} = \frac{m_3 v_3 + m_6 v_6}{m_1 + m_2}$$

Substitute numerical values and evaluate v_{cm}:

$$v_{cm} = \frac{(3\,\text{kg})(6\,\text{m/s}) + (6\,\text{kg})(3\,\text{m/s})}{3\,\text{kg} + 6\,\text{kg}} = \boxed{4.00\,\text{m/s}}$$

(*c*) Find the center of mass kinetic energy from the velocity of the center of mass:

$$K_{cm} = \tfrac{1}{2} M v_{cm}^2 = \tfrac{1}{2}(9\,\text{kg})(4\,\text{m/s})^2 = \boxed{72.0\,\text{J}}$$

(*d*) Relate the initial kinetic energy of the system to its initial kinetic energy relative to the center of mass and the kinetic energy of the center of mass:

$$K_{\text{rel}} = K_{\text{tot}} - K_{\text{cm}} = 81.0\,\text{J} - 72.0\,\text{J} = \boxed{9.00\,\text{J}}$$

113 •

Picture the Problem Let east be the positive *x* direction and north the positive *y* direction. Include both cars and the earth in the system and let the numeral 1 denote the 1500-kg car and the numeral 2 the 2000-kg car. Because the net external force acting on the system is zero, momentum is conserved in this perfectly inelastic collision.

(*a*) Express the total momentum of the system:

$$\vec{\boldsymbol{p}} = \vec{\boldsymbol{p}}_1 + \vec{\boldsymbol{p}}_2 = m_1\vec{\boldsymbol{v}}_1 + m_2\vec{\boldsymbol{v}}_2 = m_1 v_1\hat{\boldsymbol{j}} - m_2 v_2\hat{\boldsymbol{i}}$$

Substitute numerical values and evaluate $\vec{\boldsymbol{p}}$:

$$\vec{\boldsymbol{p}} = (1500\,\text{kg})(70\,\text{km/h})\hat{\boldsymbol{j}} - (2000\,\text{kg})(55\,\text{km/h})\hat{\boldsymbol{i}}$$
$$= \boxed{-\left(1.10\times10^5\,\text{kg}\cdot\text{km/h}\right)\hat{\boldsymbol{i}} + \left(1.05\times10^5\,\text{kg}\cdot\text{km/h}\right)\hat{\boldsymbol{j}}}$$

(*b*) Express the velocity of the wreckage in terms of the total momentum of the system:

$$\vec{\boldsymbol{v}}_{\text{f}} = \vec{\boldsymbol{v}}_{\text{cm}} = \frac{\vec{\boldsymbol{p}}}{M}$$

Substitute numerical values and evaluate $\vec{\boldsymbol{v}}_{\text{f}}$:

$$\vec{\boldsymbol{v}}_{\text{f}} = \frac{-\left(1.10\times10^5\,\text{kg}\cdot\text{km/h}\right)\hat{\boldsymbol{i}}}{1500\,\text{kg} + 2000\,\text{kg}} + \frac{\left(1.05\times10^5\,\text{kg}\cdot\text{km/h}\right)\hat{\boldsymbol{j}}}{1500\,\text{kg} + 2000\,\text{kg}}$$
$$= -(31.4\,\text{km/h})\,\hat{\boldsymbol{i}} + (30.0\,\text{km/h})\hat{\boldsymbol{j}}$$

Find the magnitude of the velocity of the wreckage:

$$v_{\text{f}} = \sqrt{(31.4\,\text{km/h})^2 + (30.0\,\text{km/h})^2} = \boxed{43.4\,\text{km/h}}$$

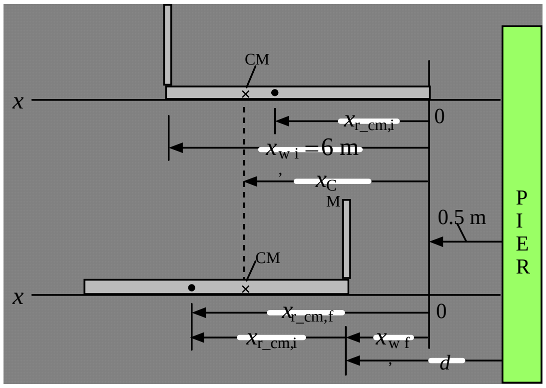
Find the direction of the velocity of the wreckage:

$$\theta = \tan^{-1}\left[\frac{30.0\,\text{km/h}}{-31.4\,\text{km/h}}\right] = -43.7°$$

$$\boxed{\text{The direction of the wreckage is } 46.3° \text{ west of north.}}$$

***114** ••

Picture the Problem Take the origin to be at the initial position of the right-hand end of raft and let the positive x direction be to the left. Let "w" denote the woman and "r" the raft, d be the distance of the end of the raft from the pier after the woman has walked to its front. The raft moves to the left as the woman moves to the right; with the center of mass of the woman-raft system remaining fixed (because $F_{\text{ext,net}} = 0$). The diagram shows the initial ($x_{\text{w,i}}$) and final ($x_{\text{w,f}}$) positions of the woman as well as the initial ($x_{\text{r\_cm,i}}$) and final ($x_{\text{r\_cm,f}}$) positions of the center of mass of the raft both before and after the woman has walked to the front of the raft.



(a) Express the distance of the raft from the pier after the woman has walked to the front of the raft:

$$d = 0.5\,\text{m} + x_{\text{f,w}} \qquad (1)$$

Express x_{cm} before the woman has walked to the front of the raft:

$$x_{\text{cm}} = \frac{m_{\text{w}} x_{\text{w,i}} + m_{\text{r}} x_{\text{r\_cm,i}}}{m_{\text{w}} + m_{\text{r}}}$$

Express x_{cm} after the woman has walked to the front of the raft:

$$x_{\text{cm}} = \frac{m_{\text{w}} x_{\text{w,f}} + m_{\text{r}} x_{\text{r\_cm,f}}}{m_{\text{w}} + m_{\text{r}}}$$

Because $F_{\text{ext,net}} = 0$, the center of mass remains fixed and we can equate these two expressions for x_{cm} to obtain:

$$m_{\text{w}} x_{\text{w,i}} + m_{\text{r}} x_{\text{r\_cm,i}} = m_{\text{w}} x_{\text{w,f}} + m_{\text{r}} x_{\text{r\_cm,f}}$$

Solve for $x_{\text{w,f}}$:

$$x_{\text{w,f}} = x_{\text{w,i}} - \frac{m_{\text{r}}}{m_{\text{w}}}\left(x_{\text{r\_cm,f}} - x_{\text{r\_cm,i}}\right)$$

From the figure it can be seen that $x_{\text{r\_cm,f}} - x_{\text{r\_cm,i}} = x_{\text{w,f}}$. Substitute $x_{\text{w,f}}$

$$x_{\text{w,f}} = \frac{m_{\text{w}} x_{\text{w,i}}}{m_{\text{w}} + m_{\text{r}}}$$

for $x_{r\_cm,f} - x_{r\_cm,i}$ and to obtain:

Substitute numerical values and evaluate $x_{w,f}$:

$$x_{w,f} = \frac{(60\,\text{kg})(6\,\text{m})}{60\,\text{kg} + 120\,\text{kg}} = 2.00\,\text{m}$$

Substitute in equation (1) to obtain:

$$d = 2.00\,\text{m} + 0.5\,\text{m} = \boxed{2.50\,\text{m}}$$

(*b*) Express the total kinetic energy of the system:

$$K_{tot} = \tfrac{1}{2} m_w v_w^2 + \tfrac{1}{2} m_r v_r^2$$

Noting that the elapsed time is 2 s, find v_w and v_r:

$$v_w = \frac{x_{w,f} - x_{w,i}}{\Delta t} = \frac{2\,\text{m} - 6\,\text{m}}{2\,\text{s}} = -2\,\text{m/s}$$

relative to the dock, and

$$v_r = \frac{x_{r,f} - x_{r,i}}{\Delta t} = \frac{2.50\,\text{m} - 0.5\,\text{m}}{2\,\text{s}} = 1\,\text{m/s},$$

also relative to the dock.

Substitute numerical values and evaluate K_{tot}:

$$K_{tot} = \tfrac{1}{2}(60\,\text{kg})(-2\,\text{m/s})^2 + \tfrac{1}{2}(120\,\text{kg})(1\,\text{m/s})^2 = \boxed{180\,\text{J}}$$

Evaluate K with the raft tied to the pier:

$$K_{tot} = \tfrac{1}{2} m_w v_w^2 = \tfrac{1}{2}(60\,\text{kg})(3\,\text{m/s})^2 = \boxed{270\,\text{J}}$$

(*c*) All the kinetic energy derives from the chemical energy of the woman and, assuming she stops via static friction, the kinetic energy is transformed into her internal energy.

(*d*) After the shot leaves the woman's hand, the raft - woman system constitutes an inertial reference frame. In that frame the shot has the same initial velocity as did the shot that had a range of 6 m in the reference frame of the land. Thus, in the raft - woman frame, the shot also has a range of 6 m and lands at the front of the raft.

115 ••

Picture the Problem Let the zero of gravitational potential energy be at the elevation of the 1-kg block. We can use conservation of energy to find the speed of the bob just before its perfectly elastic collision with the block and conservation of momentum to find the speed of the block immediately after the collision. We'll apply Newton's 2nd law to find the acceleration of the sliding block and use a constant-acceleration equation to find how far it slides before coming to rest.

(*a*) Use conservation of energy to find the speed of the bob just before its collision with the block:

$$\Delta K + \Delta U = 0$$

or

$$K_f - K_i + U_f - U_i = 0$$

Because $K_i = U_f = 0$:

$$\tfrac{1}{2} m_{ball} v_{ball}^2 + m_{ball} g \Delta h = 0$$

and

$$v_{ball} = \sqrt{2g\Delta h}$$

Substitute numerical values and evaluate v_{ball}:

$$v_{ball} = \sqrt{2(9.81\,\text{m/s}^2)(2\,\text{m})} = 6.26 \text{ m/s}$$

Because the collision is perfectly elastic and the ball and block have the same mass:

$$v_{block} = v_{ball} = \boxed{6.26\,\text{m/s}}$$

(*b*) Using a constant-acceleration equation, relate the displacement of the block to its acceleration and initial speed and solve for its displacement:

$$v_f^2 = v_i^2 + 2a_{block}\Delta x$$

Since $v_f = 0$,

$$\Delta x = \frac{-v_i^2}{2a_{block}} = \frac{-v_{block}^2}{2a_{block}}$$

Apply $\sum \vec{F} = m\vec{a}$ to the sliding block:

$$\sum F_x = -f_k = ma_{block}$$

and

$$\sum F_y = F_n - m_{block} g = 0$$

Using the definition of f_k ($\mu_k F_n$) eliminate f_k and F_n between the two equations and solve for a_{block}:

$$a_{block} = -\mu_k g$$

Substitute for a_{block} to obtain:

$$\Delta x = \frac{-v_{block}^2}{-2\mu_k g} = \frac{v_{block}^2}{2\mu_k g}$$

Substitute numerical values and evaluate Δx:

$$\Delta x = \frac{(6.26\,\text{m/s})^2}{2(0.1)(9.81\,\text{m/s}^2)} = \boxed{20.0\,\text{m}}$$

***116** ••

Picture the Problem We can use conservation of momentum in the horizontal direction to find the recoil velocity of the car along the track after the firing. Because the shell will neither rise as high nor be moving as fast at the top of its trajectory as it would be in the absence of air friction, we can apply the work-energy theorem to find the amount of thermal energy produced by the air friction.

(*a*) No. The vertical reaction force of the rails is an external force and so the momentum of the system will not be conserved.

(*b*) Use conservation of momentum in the horizontal (x) direction to obtain:

$$\Delta p_x = 0$$

or

$$mv\cos 30° - Mv_{\text{recoil}} = 0$$

Solve for and evaluate v_{recoil}:

$$v_{\text{recoil}} = \frac{mv\cos 30°}{M}$$

Substitute numerical values and evaluate v_{recoil}:

$$v_{\text{recoil}} = \frac{(200\,\text{kg})(125\,\text{m/s})\cos 30°}{5000\,\text{kg}} = \boxed{4.33\,\text{m/s}}$$

(*c*) Using the work-energy theorem, relate the thermal energy produced by air friction to the change in the energy of the system:

$$W_{\text{ext}} = W_{\text{f}} = \Delta E_{\text{sys}} = \Delta U + \Delta K$$

Substitute for ΔU and ΔK to obtain:

$$W_{\text{ext}} = mgy_{\text{f}} - mgy_{\text{i}} + \tfrac{1}{2}mv_{\text{f}}^2 - \tfrac{1}{2}mv_i^2 = mg(y_{\text{f}} - y_{\text{i}}) + \tfrac{1}{2}m(v_{\text{f}}^2 - v_i^2)$$

Substitute numerical values and evaluate W_{ext}:

$$W_{\text{ext}} = (200\,\text{kg})(9.81\,\text{m/s}^2)(180\,\text{m}) + \tfrac{1}{2}(200\,\text{kg})\left[(80\,\text{m/s})^2 - (125\,\text{m/s})^2\right] = \boxed{-569\,\text{kJ}}$$

117 ••

Picture the Problem Because this is a perfectly inelastic collision, the velocity of the block after the collision is the same as the velocity of the center of mass before the collision. The distance the block travels before hitting the floor is the product of its velocity and the time required to fall 0.8 m; which we can find using a constant-acceleration equation.

Relate the distance D to the velocity of the center of mass and the time for the block to fall to the floor:

$$D = v_{\rm cm}\Delta t$$

Relate the velocity of the center of mass to the total momentum of the system and solve for $v_{\rm cm}$:

$$\vec{P} = \sum_{\rm i} m_{\rm i}\vec{v}_{\rm i} = M\vec{v}_{\rm cm}$$

and

$$v_{\rm cm} = \frac{m_{\rm bullet}v_{\rm bullet} + m_{\rm block}v_{\rm block}}{m_{\rm bullet} + m_{\rm block}}$$

Substitute numerical values and evaluate $v_{\rm cm}$:

$$v_{\rm cm} = \frac{(0.015\,{\rm kg})(500\,{\rm m/s})}{0.015\,{\rm kg} + 0.8\,{\rm kg}} = 9.20\,{\rm m/s}$$

Using a constant-acceleration equation, find the time for the block to fall to the floor:

$$\Delta y = v_0\Delta t + \tfrac{1}{2}a(\Delta t)^2$$

$$\text{Because } v_0 = 0,\ \Delta t = \sqrt{\frac{2\Delta y}{g}}$$

Substitute to obtain:

$$D = v_{\rm cm}\sqrt{\frac{2\Delta y}{g}}$$

Substitute numerical values and evaluate D:

$$D = (9.20\,{\rm m/s})\sqrt{\frac{2(0.8\,{\rm m})}{9.81\,{\rm m/s^2}}} = \boxed{3.72\,{\rm m}}$$

118 ••

Picture the Problem Let the direction the particle whose mass is m is moving initially be the positive x direction and the direction the particle whose mass is $4m$ is moving initially be the negative y direction. We can determine the impulse delivered by $\vec{F}$ and, hence, the change in the momentum of the system from the change in the momentum of the particle whose mass is m. Knowing $\Delta\vec{p}$, we can express the final momentum of the particle whose mass is $4m$ and solve for its final velocity.

Express the impulse delivered by the force $\vec{F}$:

$$\vec{I} = \vec{F}T = \Delta\vec{p} = \vec{p}_{\rm f} - \vec{p}_{\rm i}$$
$$= m(4v)\hat{i} - mv\hat{i} = 3mv\hat{i}$$

Express $\vec{p}'_{4m}$:

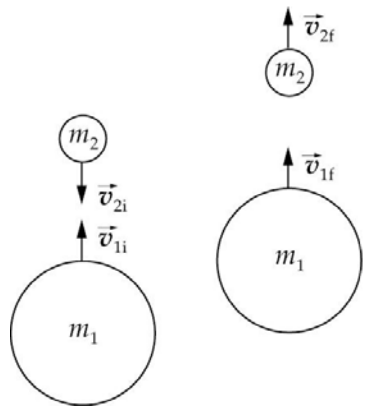
$$\vec{p}'_{4m} = 4m\vec{v}' = \vec{p}_{4m}(0) + \Delta\vec{p} = -4mv\,\hat{j} + 3mv\,\hat{i}$$

Solve for $\vec{v}'$:

$$\vec{v}' = \boxed{\tfrac{3}{4}v\,\hat{i} - v\,\hat{j}}$$

119 ••

Picture the Problem Let the numeral 1 refer to the basketball and the numeral 2 to the baseball. The left-hand side of the diagram shows the balls after the basketball's elastic collision with the floor and just before they collide. The right-hand side of the diagram shows the balls just after their collision. We can apply conservation of momentum and the definition of an elastic collision to obtain equations relating the initial and final velocities of the masses of the colliding objects that we can solve for v_{1f} and v_{2f}.



(*a*) Because both balls are in free-fall, and both are in the air for the same amount of time, they have the same velocity just before the basketball rebounds. After the basketball rebounds elastically, its velocity will have the same magnitude, but the opposite direction than just before it hit the ground.

The velocity of the basketball will be equal in magnitude but opposite in direction to the velocity of the baseball.

(*b*) Apply conservation of momentum to the collision of the balls to obtain:

$$m_1v_{1f} + m_2v_{2f} = m_1v_{1i} + m_2v_{2i} \qquad (1)$$

Relate the initial and final kinetic energies of the balls in their elastic collision:

$$\tfrac{1}{2}m_1v_{1f}^2 + \tfrac{1}{2}m_2v_{2f}^2 = \tfrac{1}{2}m_1v_{1i}^2 + \tfrac{1}{2}m_2v_{2i}^2$$

Rearrange this equation and factor to obtain:

$$m_2\left(v_{2f}^2 - v_{2i}^2\right) = m_1\left(v_{1i}^2 - v_{1f}^2\right)$$

or

$$m_2\left(v_{2f} - v_{2i}\right)\left(v_{2f} + v_{2i}\right) = m_1\left(v_{1i} - v_{1f}\right)\left(v_{1i} + v_{1f}\right) \qquad (2)$$

Rearrange equation (1) to obtain:

$$m_2\left(v_{2f} - v_{2i}\right) = m_1\left(v_{1i} - v_{1f}\right) \qquad (3)$$

Divide equation (2) by equation (3) to obtain:

$$v_{2f} + v_{2i} = v_{1i} + v_{1f}$$

Rearrange this equation to obtain equation (4):

$$v_{1f} - v_{2f} = v_{2i} - v_{1i} \quad (4)$$

Multiply equation (4) by m_2 and add it to equation (1) to obtain:

$$(m_1 + m_2)v_{1f} = (m_1 - m_2)v_{1i} + 2m_2v_{2i}$$

Solve for v_{1f} to obtain:

$$v_{1f} = \frac{m_1 - m_2}{m_1 + m_2}v_{1i} + \frac{2m_2}{m_1 + m_2}v_{2i}$$

or, because $v_{2i} = -v_{1i}$,

$$v_{1f} = \frac{m_1 - m_2}{m_1 + m_2}v_{1i} - \frac{2m_2}{m_1 + m_2}v_{1i} = \frac{m_1 - 3m_2}{m_1 + m_2}v_{1i}$$

For $m_1 = 3m_2$ and $v_{1i} = v$:

$$v_{1f} = \frac{3m_2 - 3m_2}{3m_2 + m_2}v = \boxed{0}$$

(*c*) Multiply equation (4) by m_1 and subtract it from equation (1) to obtain:

$$(m_1 + m_2)v_{2f} = (m_2 - m_1)v_{2i} + 2m_1v_{1i}$$

Solve for v_{2f} to obtain:

$$v_{2f} = \frac{2m_1}{m_1 + m_2}v_{1i} + \frac{m_2 - m_1}{m_1 + m_2}v_{2i}$$

or, because $v_{2i} = -v_{1i}$,

$$v_{2f} = \frac{2m_1}{m_1 + m_2}v_{1i} - \frac{m_2 - m_1}{m_1 + m_2}v_{1i} = \frac{3m_1 - m_2}{m_1 + m_2}v_{1i}$$

For $m_1 = 3m_2$ and $v_{1i} = v$:

$$v_{2f} = \frac{3(3m_2) - m_2}{3m_2 + m_2}v = \boxed{2v}$$

120 •••

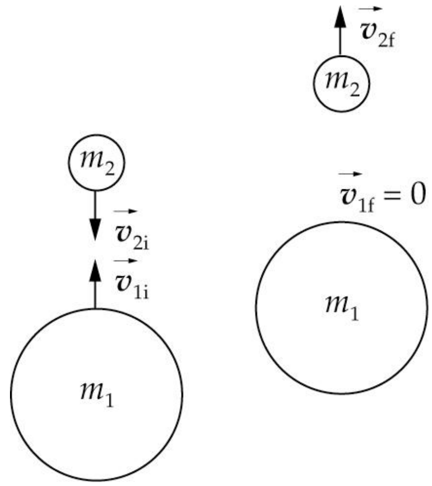
Picture the Problem In Problem 119 only two balls are dropped. They collide head on, each moving at speed v, and the collision is elastic. In this problem, as it did in Problem 119, the solution involves using the conservation of momentum equation

$$m_1v_{1f} + m_2v_{2f} = m_1v_{1i} + m_2v_{2i}$$

and the elastic collision equation

$$v_{1f} - v_{2f} = v_{2i} - v_{1i},$$

where the numeral 1 refers to the baseball, and the numeral 2 to the top ball. The diagram shows the balls just before and just after their collision. From Problem 119 we know that that $v_{1i} = 2v$ and $v_{2i} = -v$.



(*a*) Express the final speed v_{1f} of the baseball as a function of its initial speed v_{1i} and the initial speed of the top ball v_{2i} (see Problem 78):

$$v_{1f} = \frac{m_1 - m_2}{m_1 + m_2}v_{1i} + \frac{2m_2}{m_1 + m_2}v_{2i}$$

Substitute for v_{1i} and , v_{2i} to obtain:

$$v_{1f} = \frac{m_1 - m_2}{m_1 + m_2}(2v) + \frac{2m_2}{m_1 + m_2}(-v)$$

Divide the numerator and denominator of each term by m_2 to introduce the mass ratio of the upper ball to the lower ball:

$$v_{1f} = \frac{\frac{m_1}{m_2} - 1}{\frac{m_1}{m_2} + 1}(2v) + \frac{2}{\frac{m_1}{m_2} + 1}(-v)$$

Set the final speed of the baseball v_{1f} equal to zero, let x represent the mass ratio m_1/m_2, and solve for x:

$$0 = \frac{x - 1}{x + 1}(2v) + \frac{2}{x + 1}(-v)$$

and

$$x = \frac{m_1}{m_2} = \boxed{\frac{1}{2}}$$

(*b*) Apply the second of the two equations in Problem 78 to the collision between the top ball and the baseball:

$$v_{2f} = \frac{2m_1}{m_1 + m_2}v_{1i} + \frac{m_2 - m_1}{m_1 + m_2}v_{2i}$$

Substitute $v_{1i} = 2v$ and are given that $v_{2i} = -v$ to obtain:

$$v_{2f} = \frac{2m_1}{m_1 + m_2}(2v) + \frac{m_2 - m_1}{m_1 + m_2}(-v)$$

In part (*a*) we showed that $m_2 = 2m_1$. Substitute and simplify:

$$v_{3f} = \frac{2(2m_1)}{m_1 + 2m_1}(2v) - \frac{2m_1 - m_1}{m_1 + 2m_1}v$$
$$= \frac{4m_1}{3m_1}(2v) - \frac{m_1}{3m_1}v = \tfrac{8}{3}v - \tfrac{1}{3}v$$
$$= \boxed{\tfrac{7}{3}v}$$

***121 ••**

Picture the Problem Let the direction the probe is moving after its elastic collision with Saturn be the positive direction. The probe gains kinetic energy at the expense of the kinetic energy of Saturn. We'll relate the velocity of approach relative to the center of mass to u_{rec} and then to v.

(*a*) Relate the velocity of recession to the velocity of recession relative to the center of mass:

$$v = u_{rec} + v_{cm}$$

Find the velocity of approach:

$$u_{app} = -9.6\,\text{km/s} - 10.4\,\text{km/s} = -20.0\,\text{km/s}$$

Relate the relative velocity of approach to the relative velocity of recession for an elastic collision:

$$u_{rec} = -u_{app} = 20.0\,\text{km/s}$$

Because Saturn is so much more massive than the space probe:

$$v_{cm} = v_{Saturn} = 9.6\,\text{km/s}$$

Substitute and evaluate v:

$$v = u_{rec} + v_{cm} = 20\,\text{km/s} + 9.6\,\text{km/s} = \boxed{29.6\,\text{km/s}}$$

(*b*) Express the ratio of the final kinetic energy to the initial kinetic energy:

$$\frac{K_f}{K_i} = \frac{\tfrac{1}{2}Mv_{rec}^2}{\tfrac{1}{2}Mv_i^2} = \left(\frac{v_{rec}}{v_i}\right)^2$$
$$= \left(\frac{29.6\,\text{km/s}}{10.4\,\text{km/s}}\right)^2 = \boxed{8.10}$$

$$\boxed{\text{The energy comes from an immeasurably small slowing of Saturn.}}$$

***122 ••**

Picture the Problem We can use the relationships $P = c\Delta m$ and $\Delta E = \Delta mc^2$ to show that $P = \Delta E/c$. We can then equate this expression with the change in momentum of the flashlight to find the latter's final velocity.

(*a*) Express the momentum of the mass lost (i.e., carried away by the light) by the flashlight:

$$P = c\Delta m$$

Relate the energy carried away by the light to the mass lost by the flashlight:

$$\Delta m = \frac{\Delta E}{c^2}$$

Substitute to obtain:

$$P = c\frac{\Delta E}{c^2} = \boxed{\frac{\Delta E}{c}}$$

(*b*) Relate the final momentum of the flashlight to ΔE:

$$\frac{\Delta E}{c} = \Delta p = mv$$

because the flashlight is initially at rest.

Solve for *v*:

$$v = \frac{\Delta E}{mc}$$

Substitute numerical values and evaluate *v*:

$$v = \frac{1.5\times10^3\text{ J}}{(1.5\text{ kg})(2.998\times10^8\text{ m/s})} = 3.33\times10^{-6}\text{ m/s} = \boxed{3.33\,\mu\text{m/s}}$$

123 •

Picture the Problem We can equate the change in momentum of the block to the momentum of the beam of light and relate the momentum of the beam of light to the mass converted to produce the beam. Combining these expressions will allow us to find the speed attained by the block.

Relate the change in momentum of the block to the momentum of the beam:

$$(M - m)v = P_{\text{beam}}$$

because the block is initially at rest.

Express the momentum of the mass converted into a well-collimated beam of light:

$$P_{\text{beam}} = mc$$

Substitute to obtain:

$$(M - m)v = mc$$

Solve for *v*:

$$v = \frac{mc}{M - m}$$

Substitute numerical values and evaluate v:

$$v = \frac{(0.001\,\text{kg})(2.998\times10^8\ \text{m/s})}{1\,\text{kg}-0.001\,\text{kg}} = \boxed{3.00\times10^5\ \text{m/s}}$$

124 ••

Picture the Problem Let the origin of the coordinate system be at the end of the boat at which your friend is sitting prior to changing places. If we let the system include you and your friend, the boat, the water and the earth, then $F_{\text{ext,net}} = 0$ and the center of mass is at the same location after you change places as it was before you shifted.

Express the center of mass of the system prior to changing places:

$$x_{\text{cm}} = \frac{m_{\text{boat}}x_{\text{boat}} + m_{\text{you}}x_{\text{you}} + mx_{\text{friend}}}{m_{\text{boat}} + m_{\text{you}} + m_{\text{friend}}} = \frac{x_{\text{you}}(m_{\text{boat}} + m_{\text{you}}) + mx_{\text{friend}}}{m_{\text{boat}} + m_{\text{you}} + m}$$

Substitute numerical values and simplify to obtain an expression for x_{cm} in terms of m:

$$x_{\text{cm}} = \frac{(2\,\text{m})(60\,\text{kg}+80\,\text{kg})+(0)m}{60\,\text{kg}+80\,\text{kg}+m} = \frac{280\,\text{kg}\cdot\text{m}}{140\,\text{kg}+m}$$

Find the center of mass of the system after changing places:

$$x'_{\text{cm}} = \frac{m_{\text{boat}}x_{\text{boat}} + m_{\text{you}}x_{\text{you}} + mx_{\text{friend}}}{m_{\text{boat}} + m_{\text{you}} + m_{\text{friend}}} = \frac{(m_{\text{boat}}+m)(2\,\text{m}\pm0.2\,\text{m})}{m_{\text{boat}} + m_{\text{you}} + m} + \frac{m_{\text{you}}(\pm0.2\,\text{m})}{m_{\text{boat}} + m_{\text{you}} + m}$$

Substitute numerical values and simplify to obtain:

$$x'_{\text{cm}} = \frac{(60\,\text{kg}+m)(2\,\text{m}\pm0.2\,\text{m})}{60\,\text{kg}+80\,\text{kg}+m} + \frac{(80\,\text{kg})(\pm0.2\,\text{m})}{60\,\text{kg}+80\,\text{kg}+m} = \frac{120\,\text{kg}\cdot\text{m}\pm12\,\text{kg}\cdot\text{m}}{140\,\text{kg}+m} + \frac{(2\,\text{m})m\pm0.2m\,\text{m}\pm16\,\text{kg}\cdot\text{m}}{140\,\text{kg}+m}$$

Because $F_{\text{ext,net}} = 0$, $x'_{\text{cm}} = x_{\text{cm}}$. Equate the two expressions and solve for m to obtain:

$$m = \frac{(160\pm28)}{(2\pm0.2)}\,\text{kg}$$

Calculate the largest possible mass for your friend:

$$m = \frac{(160+28)}{(2-0.2)}\,\text{kg} = \boxed{104\,\text{kg}}$$

Calculate the smallest possible mass for your friend:

$$m = \frac{(160 - 28)}{(2 + 0.2)}\text{kg} = \boxed{60.0\,\text{kg}}$$

125 ••

Picture the Problem Let the system include the woman, both vehicles, and the earth. Then $F_{\text{ext,net}} = 0$ and $a_{\text{cm}} = 0$. Include the mass of the man in the mass of the truck. We can use Newton's 2nd and 3rd laws to find the acceleration of the truck and net force acting on both the car and the truck.

(*a*) Relate the action and reaction forces acting on the car and truck:

$$F_{\text{car}} = F_{\text{truck}}$$

or

$$m_{\text{car}}a_{\text{car}} = m_{\text{truck+woman}}a_{\text{truck}}$$

Solve for the acceleration of the truck:

$$a_{\text{truck}} = \frac{m_{\text{car}}a_{\text{car}}}{m_{\text{truck+woman}}}$$

Substitute numerical values and evaluate a_{truck}:

$$a_{\text{truck}} = \frac{(800\,\text{kg})(1.2\,\text{m/s}^2)}{1600\,\text{kg}} = \boxed{0.600\,\text{m/s}^2}$$

(*b*) Apply Newton's 2nd law to either vehicle to obtain:

$$F_{\text{net}} = m_{\text{car}}a_{\text{car}}$$

Substitute numerical values and evaluate F_{net}:

$$F_{\text{net}} = (800\,\text{kg})(1.2\,\text{m/s}^2) = \boxed{960\,\text{N}}$$

126 ••

Picture the Problem Let the system include the block, the putty, and the earth. Then $F_{\text{ext,net}} = 0$ and momentum is conserved in this perfectly inelastic collision. We'll use conservation of momentum to relate the after-collision velocity of the block plus blob and conservation of energy to find their after-collision velocity.

Noting that, because this is a perfectly elastic collision, the final velocity of the block plus blob is the velocity of the center of mass, use conservation of momentum to relate the velocity of the center of mass to the velocity of the glob before the collision:

$$p_{\text{i}} = p_{\text{f}}$$

or

$$m_{\text{gl}}v_{\text{gl}} = Mv_{\text{cm}}$$

where $M = m_{\text{gl}} + m_{\text{bl}}$.

Solve for v_{gl} to obtain:

$$v_{gl} = \frac{M}{m_{gl}} v_{cm} \qquad (1)$$

Use conservation of energy to find the initial energy of the block plus glob:

$$\Delta K + \Delta U + W_f = 0$$

Because $\Delta U = K_f = 0$,

$$-\tfrac{1}{2} M v_{cm}^2 + f_k \Delta x = 0$$

Use $f_k = \mu_k Mg$ to eliminate f_k and solve for v_{cm}:

$$v_{cm} = \sqrt{2\mu_k g \Delta x}$$

Substitute numerical values and evaluate v_{cm}:

$$v_{cm} = \sqrt{2(0.4)(9.81\,\text{m/s}^2)(0.15\,\text{m})} = 1.08\,\text{m/s}$$

Substitute numerical values in equation (1) and evaluate v_{gl}:

$$v_{gl} = \frac{13\,\text{kg} + 0.4\,\text{kg}}{0.4\,\text{kg}}(1.08\,\text{m/s}) = \boxed{36.2\,\text{m/s}}$$

***127 ••**

Picture the Problem Let the direction the moving car was traveling before the collision be the positive *x* direction. Let the numeral 1 denote this car and the numeral 2 the car that is stopped at the stop sign and the system include both cars and the earth. We can use conservation of momentum to relate the speed of the initially-moving car to the speed of the meshed cars immediately after their perfectly inelastic collision and conservation of energy to find the initial speed of the meshed cars.

Using conservation of momentum, relate the before-collision velocity to the after-collision velocity of the meshed cars:

$$p_i = p_f$$

or

$$m_1 v_1 = (m_1 + m_2)V$$

Solve for v_1:

$$v_1 = \frac{m_1 + m_2}{m_1} V = \left(1 + \frac{m_2}{m_1}\right) V$$

Using conservation of energy, relate the initial kinetic energy of the meshed cars to the work done by friction in bringing them to a stop:

$$\Delta K + \Delta E_{thermal} = 0$$

or, because $K_f = 0$ and $\Delta E_{thermal} = f\Delta s$,

$$-K_i + f_k \Delta s = 0$$

Substitute for *Ki* and, using $f_k = \mu_k F_n = \mu_k Mg$, eliminate f_k to

$$-\tfrac{1}{2} M V^2 + \mu_k Mg \Delta x = 0$$

obtain:

Solve for V: $V = \sqrt{2\mu_k g\Delta x}$

Substitute to obtain: $v_1 = \left(1 + \frac{m_2}{m_1}\right)\sqrt{2\mu_k g\Delta x}$

Substitute numerical values and evaluate v_1:

$$v_1 = \left(1 + \frac{900\,\text{kg}}{1200\,\text{kg}}\right)\sqrt{2(0.92)(9.81\,\text{m/s}^2)(0.76\,\text{m})} = 6.48\,\text{m/s} = 23.3\,\text{km/h}$$

$$\boxed{\text{The driver was not telling the truth. He was traveling at 23.3 km/h.}}$$

128 ••

Picture the Problem Let the zero of gravitational potential energy be at the lowest point of the bob's swing and note that the bob can swing either forward or backward after the collision. We'll use both conservation of momentum and conservation of energy to relate the velocities of the bob and the block before and after their collision.

Express the kinetic energy of the block in terms of its after-collision momentum: $K_{\text{m}} = \frac{p_m^2}{2m}$

Solve for m to obtain: $m = \frac{p_m^2}{2K_m}$ (1)

Use conservation of energy to relate K_{m} to the change in the potential energy of the bob:

$\Delta K + \Delta U = 0$

or, because $K_{\text{i}} = 0$,

$K_m + U_{\text{f}} - U_{\text{i}} = 0$

Solve for K_m:

$$\begin{aligned} K_m &= -U_{\text{f}} + U_{\text{i}} \\ &= m_{\text{bob}} g\left[L(1-\cos\theta_{\text{i}}) - L(1-\cos\theta_{\text{f}})\right] \\ &= m_{\text{bob}} gL\left[\cos\theta_{\text{f}} - \cos\theta_{\text{i}}\right] \end{aligned}$$

Substitute numerical values and evaluate K_m:

$$K_m = (0.4\,\text{kg})(9.81\,\text{m/s}^2)(1.6\,\text{m})[\cos 5.73° - \cos 53°] = 2.47\,\text{J}$$

Use conservation of energy to find the velocity of the bob just before its collision with the block:

$\Delta K + \Delta U = 0$

or, because $K_i = U_f = 0$,

$K_f - U_i = 0$

$\therefore \frac{1}{2} m_{bob} v^2 - m_{bob} gL(1 - \cos\theta_i) = 0$

or

$v = \sqrt{2gL(1 - \cos\theta_i)}$

Substitute numerical values and evaluate v:

$$v = \sqrt{2(9.81\,\text{m/s}^2)(1.6\,\text{m})(1 - \cos 53°)} = 3.544\,\text{m/s}$$

Use conservation of energy to find the velocity of the bob just after its collision with the block:

$\Delta K + \Delta U = 0$

or, because $K_f = U_i = 0$,

$-K_i + U_f = 0$

Substitute for K_i and U_f to obtain:

$-\frac{1}{2} m_{bob} v'^2 + m_{bob} gL(1 - \cos\theta_f) = 0$

Solve for v':

$v' = \sqrt{2gL(1 - \cos\theta_f)}$

Substitute numerical values and evaluate v':

$$v' = \sqrt{2(9.81\,\text{m/s}^2)(1.6\,\text{m})(1 - \cos 5.73°)} = 0.396\,\text{m/s}$$

Use conservation of momentum to relate p_m after the collision to the momentum of the bob just before and just after the collision:

$p_i = p_f$

or

$m_{bob} v = m_{bob} v' \pm p_m$

Solve for and evaluate p_m:

$$p_m = m_{bob} v \pm m_{bob} v' = (0.4\,\text{kg})(3.544\,\text{m/s} \pm 0.396\,\text{m/s}) = 1.418\,\text{kg}\cdot\text{m/s} \pm 0.158\,\text{kg}\cdot\text{m/s}$$

Find the larger value for p_m:

$$p_m = 1.418\,\text{kg}\cdot\text{m/s} + 0.158\,\text{kg}\cdot\text{m/s} = 1.576\,\text{kg}\cdot\text{m/s}$$

Find the smaller value for p_m:

$$p_m = 1.418\,\text{kg}\cdot\text{m/s} - 0.158\,\text{kg}\cdot\text{m/s} = 1.260\,\text{kg}\cdot\text{m/s}$$

Substitute in equation (1) to determine the two values for m:

$$m = \frac{(1.576\,\text{kg}\cdot\text{m/s})^2}{2(2.47\,\text{J})} = \boxed{0.503\,\text{kg}}$$

or

$$m = \frac{(1.260\,\text{kg}\cdot\text{m/s})^2}{2(2.47\,\text{J})} = \boxed{0.321\,\text{kg}}$$

129 ••

Picture the Problem Choose the zero of gravitational potential energy at the location of the spring's maximum compression. Let the system include the spring, the blocks, and the earth. Then the net external force is zero as is work done against friction. We can use conservation of energy to relate the energy transformations taking place during the evolution of this system.

Apply conservation of energy:

$$\Delta K + \Delta U_g + \Delta U_s = 0$$

Because $\Delta K = 0$:

$$\Delta U_g + \Delta U_s = 0$$

Express the change in the gravitational potential energy:

$$\Delta U_g = -mg\Delta h - Mgx\sin\theta$$

Express the change in the potential energy of the spring:

$$\Delta U_s = \tfrac{1}{2}kx^2$$

Substitute to obtain:

$$-mg\Delta h - Mgx\sin\theta + \tfrac{1}{2}kx^2 = 0$$

Solve for M:

$$M = \frac{\tfrac{1}{2}kx^2 - mg\Delta h}{gx\sin 30°} = \frac{kx}{g} - \frac{2m\Delta h}{x}$$

Relate Δh to the initial and rebound positions of the block whose mass is m:

$$\Delta h = (4\,\text{m} - 2.56\,\text{m})\sin 30° = 0.720\,\text{m}$$

Substitute numerical values and evaluate M:

$$M = \frac{(11\times10^3\,\text{N/m})(0.04\,\text{m})}{9.81\,\text{m/s}^2} - \frac{2(1\,\text{kg})(0.72\,\text{m})}{0.04\,\text{m}} = \boxed{8.85\,\text{kg}}$$

***130** ••

Picture the Problem By symmetry, $x_{cm} = 0$. Let σ be the mass per unit area of the disk. The mass of the modified disk is the difference between the mass of the whole disk and the mass that has been removed.

Start with the definition of y_{cm}:

$$y_{cm}=\frac{\sum_i m_i y_i}{M-m_{hole}}=\frac{m_{disk}y_{disk}-m_{hole}y_{hole}}{M-m_{hole}}$$

Express the mass of the complete disk:

$$M=\sigma A=\sigma\pi r^2$$

Express the mass of the material removed:

$$m_{hole}=\sigma\pi\left(\frac{r}{2}\right)^2=\tfrac{1}{4}\sigma\pi r^2=\tfrac{1}{4}M$$

Substitute and simplify to obtain:

$$y_{cm}=\frac{M(0)-\left(\frac{1}{4}M\right)\left(-\frac{1}{2}r\right)}{M-\frac{1}{4}M}=\boxed{\tfrac{1}{6}r}$$

131 ••

Picture the Problem Let the horizontal axis by the *y* axis and the vertical axis the *z* axis. By symmetry, $x_{cm}=y_{cm}=0$. Let ρ be the mass per unit volume of the sphere. The mass of the modified sphere is the difference between the mass of the whole sphere and the mass that has been removed.

Start with the definition of y_{cm}:

$$z_{cm}=\frac{\sum_i m_i y_i}{M-m_{hole}}=\frac{m_{sphere}y_{sphere}-m_{hole}y_{hole}}{M-m_{hole}}$$

Express the mass of the complete sphere:

$$M=\rho V=\tfrac{4}{3}\rho\pi r^3$$

Express the mass of the material removed:

$$m_{hole}=\tfrac{4}{3}\rho\pi\left(\frac{r}{2}\right)^3=\tfrac{1}{8}\left(\tfrac{4}{3}\rho\pi r^3\right)=\tfrac{1}{8}M$$

Substitute and simplify to obtain:

$$z_{cm}=\frac{M(0)-\left(\frac{1}{8}M\right)\left(-\frac{1}{2}r\right)}{M-\frac{1}{8}M}=\boxed{\tfrac{1}{14}r}$$

***132 ••**

Picture the Problem In this elastic head-on collision, the kinetic energy of recoiling nucleus is the difference between the initial and final kinetic energies of the neutron. We can derive the indicated results by using both conservation of energy and conservation of momentum and writing the kinetic energies in terms of the momenta of the particles before and after the collision.

(*a*) Use conservation of energy to relate the kinetic energies of the particles before and after the collision:

$$\frac{p_{ni}^2}{2m} = \frac{p_{nf}^2}{2m} + \frac{p_{nucleus}^2}{2M} \qquad (1)$$

Apply conservation of momentum to obtain a second relationship between the initial and final momenta:

$$p_{ni} = p_{nf} + p_{nucleus} \qquad (2)$$

Eliminate p_{nf} in equation (1) using equation (2):

$$\frac{p_{nucleus}}{2M} + \frac{p_{nucleus}}{2m} - \frac{p_{ni}}{m} = 0 \qquad (3)$$

Use equation (3) to write $p_{ni}^2/2m$ in terms of $p_{nucleus}$:

$$\frac{p_{ni}^2}{2m} = K_n = \frac{p_{nucleus}^2(M+m)^2}{8M^2m} \qquad (4)$$

Use equation (4) to express $K_{nucleus} = p_{nucleus}^2/2M$ in terms of K_n:

$$K_{nucleus} = \boxed{K_n\left[\frac{4Mm}{(M+m)^2}\right]} \qquad (5)$$

(*b*) Relate the *change* in the kinetic energy of the neutron to the after-collision kinetic energy of the nucleus:

$$\Delta K_n = -K_{nucleus}$$

Using equation (5), express the fraction of the energy lost in the collision:

$$\frac{-\Delta K_n}{K_n} = \boxed{\frac{4Mm}{(M+m)^2} = \frac{4\dfrac{m}{M}}{\left(1+\dfrac{m}{M}\right)^2}}$$

133 ••

Picture the Problem Problem 132 (*b*) provides an expression for the fractional loss of energy per collision.

(*a*) Using the result of Problem 132 (*b*), express the fractional loss of energy per collision:

$$\frac{K_{nf}}{K_{ni}} = \frac{K_{ni} - \Delta K_n}{E_0} = \frac{(M-m)^2}{(M+m)^2}$$

Evaluate this fraction to obtain:

$$\frac{K_{nf}}{E_0} = \frac{(12m-m)^2}{(12m+m)^2} = 0.716$$

Express the kinetic energy of one

$$K_{nf} = \boxed{0.716^N E_0}$$

neutron after *N* collisions:

(*b*) Substitute for K_{nf} and E_0 to obtain:

$$0.716^N = 10^{-8}$$

Take the logarithm of both sides of the equation and solve for *N*:

$$N = \frac{-8}{\log 0.716} \approx \boxed{55}$$

134 ••

Picture the Problem We can relate the number of collisions needed to reduce the energy of a neutron from 2 MeV to 0.02 eV to the fractional energy loss per collision and solve the resulting exponential equation for *N*.

(*a*) Using the result of Problem 132 (*b*), express the fractional loss of energy per collision:

$$\frac{K_{nf}}{K_{ni}} = \frac{K_{ni} - \Delta K_n}{E_0} = \frac{K_{ni} - 0.63K_{ni}}{K_{ni}} = 0.37$$

Express the kinetic energy of one neutron after *N* collisions:

$$K_{nf} = \boxed{0.37^N E_0}$$

Substitute for K_{nf} and E_0 to obtain:

$$0.37^N = 10^{-8}$$

Take the logarithm of both sides of the equation and solve for *N*:

$$N = \frac{-8}{\log 0.37} \approx \boxed{19}$$

(*b*) Proceed as in (*a*) to obtain:

$$\frac{K_{nf}}{K_{ni}} = \frac{K_{ni} - \Delta K_n}{E_0} = \frac{K_{ni} - 0.11K_{ni}}{K_{ni}} = 0.89$$

Express the kinetic energy of one neutron after *N* collisions:

$$K_{nf} = \boxed{0.89^N E_0}$$

Substitute for K_{nf} and E_0 to obtain:

$$0.89^N = 10^{-8}$$

Take the logarithm of both sides of the equation and solve for *N*:

$$N = \frac{-8}{\log 0.89} \approx \boxed{158}$$

135 ••

Picture the Problem Let $\lambda = M/L$ be the mass per unit length of the rope, the subscript 1 refer to the portion of the rope that is being supported by the force F at any given time, and the subscript 2 refer to the rope that is still on the table at any given time. We can find the height h_{cm} of the center of mass as a function of time and then differentiate this expression twice to find the acceleration of the center of mass.

(*a*) Apply the definition of the center of mass to obtain:

$$h_{cm} = \frac{m_1 h_{1,cm} + m_2 h_{2,cm}}{M} \qquad (1)$$

From the definition of λ we have:

$$\frac{M}{L} = \frac{m_1}{vt} \Rightarrow m_1 = \frac{M}{L}vt$$

$h_{1,cm}$ and $h_{2,cm}$ are given by :

$$h_{1,cm} = \frac{1}{2}vt \text{ and } h_{2,cm} = 0$$

Substitute for m_1, $h_{1,cm}$, and $h_{2,cm}$ in equation (1) and simplify to obtain:

$$h_{cm} = \frac{\left(\frac{M}{L}vt\right)h_{1,cm} + m_2(0)}{M} = \boxed{\frac{v^2}{2L}t^2}$$

(*b*) Differentiate h_{cm} twice to obtain a_{cm}:

$$\frac{dh_{cm}}{dt} = 2\left(\frac{v^2}{2L}\right)t = \frac{v^2}{L}t$$

and

$$\frac{d^2h_{cm}}{dt^2} = a_{cm} = \boxed{\frac{v^2}{L}}$$

(*c*) Letting N represent the normal force that the table exerts on the rope, apply $\sum F_y = ma_{cm}$ to the rope to obtain:

$$F + N - Mg = Ma_{cm}$$

Solve for F, substitute for a_{cm} and N to obtain:

$$F = Mg + Ma_{cm} - N$$
$$= Mg + M\frac{v^2}{L} - m_2 g$$

Use the definition of λ again to obtain:

$$\frac{m_2}{L - vt} = \frac{M}{L} \Rightarrow m_2 = M\left(1 - \frac{vt}{L}\right)$$

Substitute for m_2 and simplify:

$$F = Mg + M\frac{v^2}{L} - M\left(1 - \frac{vt}{L}\right)g = M\left(g + \frac{v^2}{L} - g + \frac{vt}{L}g\right) = Mg\left(\frac{v^2}{gL} + \frac{vt}{L}\right)$$

$$= \boxed{\frac{vt}{L}\left(\frac{v}{gt} + 1\right)Mg}$$

136 ••

Picture the Problem The free-body diagram shows the forces acting on the platform when the spring is partially compressed. The scale reading is the force the scale exerts on the platform and is represented on the FBD by F_n. We can use Newton's 2nd law to determine the scale reading in part (*a*). We'll use both conservation of energy and momentum to obtain the scale reading when the ball collides inelastically with the cup.

(*a*) Apply $\sum F_y = ma_y$ to the spring when it is compressed a distance *d*:

$$F_n - m_p g - F_{\text{ball on spring}} = 0$$

Solve for F_n:

$$F_n = m_p g + F_{\text{ball on spring}}$$
$$= m_p g + kd$$
$$= m_p g + k\left(\frac{m_b g}{k}\right)$$
$$= \boxed{m_p g + m_b g = (m_p + m_b)g}$$

(*b*) Letting the zero of gravitational energy be at the initial elevation of the cup and v_{bi} represent the velocity of the ball just before it hits the cup, use conservation of energy to find this velocity:

$$\Delta K + \Delta U_g = 0 \text{ where } K_i = U_{gf} = 0$$
$$\therefore \tfrac{1}{2}m_b v_{bi}^2 - mgh = 0$$
and
$$v_{bi} = \sqrt{2gh}$$

Use conservation of momentum to

$$\vec{p}_i = \vec{p}_f$$

find the velocity of the center of mass:

$$\therefore v_{\text{cm}} = \frac{m_{\text{b}}v_{\text{bi}}}{m_{\text{b}} + m_{\text{c}}} = \sqrt{2gh}\left[\frac{m_{\text{b}}}{m_{\text{b}} + m_{\text{c}}}\right]$$

Apply conservation of energy to the collision to obtain:

$$\Delta K_{\text{cm}} + \Delta U_{\text{s}} = 0$$

or, with $K_{\text{f}} = U_{\text{si}} = 0$,

$$-\tfrac{1}{2}(m_{\text{b}} + m_{\text{c}})v_{\text{cm}}^2 + \tfrac{1}{2}kx^2 = 0$$

Substitute for v_{cm} and solve for kx^2:

$$\begin{aligned} kx^2 &= (m_{\text{b}} + m_{\text{c}})v_{\text{cm}}^2 \\ &= 2gh(m_{\text{b}} + m_{\text{c}})\left[\frac{m_{\text{b}}}{m_{\text{b}} + m_{\text{c}}}\right]^2 \\ &= \frac{2ghm_{\text{b}}^2}{m_{\text{b}} + m_{\text{c}}} \end{aligned}$$

Solve for x:

$$x = m_{\text{b}}\sqrt{\frac{2gh}{k(m_{\text{b}} + m_{\text{c}})}}$$

From part (a):

$$\begin{aligned} F_{\text{n}} &= m_{\text{p}}g + kx \\ &= m_{\text{p}}g + km_{\text{b}}\sqrt{\frac{2gh}{k(m_{\text{b}} + m_{\text{c}})}} \\ &= \boxed{g\left(m_{\text{p}} + m_{\text{b}}\sqrt{\frac{2kh}{g(m_{\text{b}} + m_{\text{c}})}}\right)} \end{aligned}$$

(c) Because the collision is inelastic, the ball never returns to its original height.

137 ••

Picture the Problem Let the direction that astronaut 1 first throws the ball be the positive direction and let v_{b} be the initial speed of the ball in the laboratory frame. Note that each collision is perfectly inelastic. We can apply conservation of momentum and the definition of the speed of the ball relative to the thrower to each of the perfectly inelastic collisions to express the final speeds of each astronaut after one throw and one catch.

Use conservation of momentum to relate the speeds of astronaut 1 and the ball after the first throw:

$$m_1v_1 + m_{\text{b}}v_{\text{b}} = 0 \quad (1)$$

Relate the speed of the ball in the laboratory frame to its speed relative

$$v = v_{\text{b}} - v_1 \quad (2)$$

to astronaut 1:

Eliminate v_b between equations (1) and (2) and solve for v_1:

$$v_1 = -\frac{m_b}{m_1 + m_b} v \quad (3)$$

Substitute equation (3) in equation (2) and solve for v_b:

$$v_b = \frac{m_1}{m_1 + m_b} v \quad (4)$$

Apply conservation of momentum to express the speed of astronaut 2 and the ball after the first catch:

$$0 = m_b v_b = (m_2 + m_b) v_2 \quad (5)$$

Solve for v_2:

$$v_2 = \frac{m_b}{m_2 + m_b} v_b \quad (6)$$

Express v_2 in terms of v by substituting equation (4) in equation (6):

$$v_2 = \frac{m_b}{m_2 + m_b} \frac{m_1}{m_1 + m_b} v = \left[\frac{m_b m_1}{(m_2 + m_b)(m_1 + m_b)}\right] v \quad (7)$$

Use conservation of momentum to express the speed of astronaut 2 and the ball after she throws the ball:

$$(m_2 + m_b) v_2 = m_b v_{bf} + m_2 v_{2f} \quad (8)$$

Relate the speed of the ball in the laboratory frame to its speed relative to astronaut 2:

$$v = v_{2f} - v_{bf} \quad (9)$$

Eliminate v_{bf} between equations (8) and (9) and solve for v_{2f}:

$$v_{2f} = \boxed{\left(\frac{m_b}{m_2 + m_b}\right)\left[1 + \frac{m_1}{m_1 + m_b}\right] v} \quad (10)$$

Substitute equation (10) in equation (9) and solve for v_{bf}:

$$v_{bf} = -\left[1 - \frac{m_b}{m_2 + m_b}\right] \times \left[1 + \frac{m_1}{m_1 + m_b}\right] v \quad (11)$$

Apply conservation of momentum to express the speed of astronaut 1 and the ball after she catches the ball:

$$(m_1 + m_b) v_{1f} = m_b v_{bf} + m_1 v_1 \quad (12)$$

Using equations (3) and (11), eliminate v_{bf} and v_1 in equation (12) and solve for v_{1f}:

$$v_{1f} = \boxed{-\frac{m_2 m_b (2m_1 + m_b)}{(m_1 + m_b)^2 (m_2 + m_b)} v}$$

***138** ••

Picture the Problem We can use the definition of the center of mass of a system containing multiple objects to locate the center of mass of the earth–moon system. Any object external to the system will exert accelerating forces on the system.

(*a*) Express the center of mass of the earth–moon system relative to the center of the earth:

$$M\vec{r}_{cm} = \sum_i m_i \vec{r}_i$$

or

$$r_{cm} = \frac{M_e(0) + m_m r_{em}}{M_e + m_m} = \frac{m_m r_{em}}{M_e + m_m} = \frac{r_{em}}{\frac{M_e}{m_m} + 1}$$

Substitute numerical values and evaluate r_{cm}:

$$r_{cm} = \frac{3.84 \times 10^5 \text{ km}}{81.3 + 1} = \boxed{4670 \text{ km}}$$

Because this distance is less than the radius of the earth, the position of the center of mass of the earth – moon system is below the surface of the earth.

(*b*) Any object not in the earth – moon system exerts forces on the system, e.g., the sun and other planets.

(*c*) Because the sun exerts the dominant external force on the earth – moon system, the acceleration of the system is toward the sun.

(*d*) Because the center of mass is at a fixed distance from the sun, the distance d moved by the earth in this time interval is:

$$d = 2r_{em} = 2(4670 \text{ km}) = \boxed{9340 \text{ km}}$$

139 ••

Picture the Problem Let the numeral 2 refer to you and the numeral 1 to the water leaving the hose. Apply conservation of momentum to the system consisting of yourself, the water, and the earth and then differentiate this expression to relate your recoil acceleration to your mass, the speed of the water, and the rate at which the water is leaving the hose.

Use conservation of momentum to relate your recoil velocity to the velocity of the water leaving the hose:

$$\vec{p}_1 + \vec{p}_2 = 0$$

or

$$m_1 v_1 + m_2 v_2 = 0$$

Differentiate this expression with respect to t:

$$m_1 \frac{dv_1}{dt} + v_1 \frac{dm_1}{dt} + m_2 \frac{dv_2}{dt} + v_2 \frac{dm_2}{dt} = 0$$

or

$$m_1 a_1 + v_1 \frac{dm_1}{dt} + m a_2 + v_2 \frac{dm_2}{dt} = 0$$

Because the acceleration of the water leaving the hose, a_1, is zero … as is $\frac{dm_2}{dt}$, the rate at which you are losing mass:

$$v_1 \frac{dm_1}{dt} + m_2 a_2 = 0$$

and

$$a_2 = -\frac{v_1}{m_2}\frac{dm_1}{dt}$$

Substitute numerical values and evaluate a_2:

$$a_2 = -\frac{30\,\text{m/s}}{75\,\text{kg}}(2.4\,\text{kg/s})$$

$$= \boxed{-0.960\,\text{m/s}^2}$$

***140 •••**

Picture the Problem Take the zero of gravitational potential energy to be at the elevation of the pan and let the system include the balance, the beads, and the earth. We can use conservation of energy to find the vertical component of the velocity of the beads as they hit the pan and then calculate the net downward force on the pan from Newton's 2nd law.

Use conservation of energy to relate the y component of the bead's velocity as it hits the pan to its height of fall:

$$\Delta K + \Delta U = 0$$

or, because $K_i = U_f = 0$,

$$\tfrac{1}{2} m v_y^2 - mgh = 0$$

Solve for v_y:

$$v_y = \sqrt{2gh}$$

Substitute numerical values and evaluate v_y:

$$v_y = \sqrt{2(9.81\,\text{m/s}^2)(0.5\,\text{m})} = 3.13\,\text{m/s}$$

Express the change in momentum in the y direction per bead:

$$\Delta p_y = p_{yf} - p_{yi} = m v_y - (-m v_y) = 2 m v_y$$

Use Newton's 2nd law to express the net force in the y direction exerted on the pan by the beads:

$$F_{\text{net},y} = N\frac{\Delta p_y}{\Delta t}$$

Letting M represent the mass to be placed on the other pan, equate its weight to the net force exerted by the beads, substitute for Δp_y, and solve for M:

$$Mg = N\frac{\Delta p_y}{\Delta t}$$

and

$$M = \frac{N}{\Delta t}\left(\frac{2mv_y}{g}\right)$$

Substitute numerical values and evaluate M:

$$M = (100/\text{s})\frac{[2(0.0005\,\text{kg})(3.13\,\text{m/s})]}{9.81\,\text{m/s}^2}$$

$$= \boxed{31.9\,\text{g}}$$

141 •••

Picture the Problem Assume that the connecting rod goes halfway through both balls, i.e., the centers of mass of the balls are separated by L. Let the system include the dumbbell, the wall and floor, and the earth. Let the zero of gravitational potential be at the center of mass of the lower ball and use conservation of energy to relate the speeds of the balls to the potential energy of the system. By symmetry, the speeds will be equal when the angle with the vertical is 45°.

Use conservation of energy to express the relationship between the initial and final energies of the system:

$$E_\text{i} = E_\text{f}$$

Express the initial energy of the system:

$$E_\text{i} = mgL$$

Express the energy of the system when the angle with the vertical is 45°:

$$E_\text{f} = mgL\sin 45° + \tfrac{1}{2}(2m)v^2$$

Substitute to obtain:

$$gL = gL\left(\frac{1}{\sqrt{2}}\right) + v^2$$

Solve for v:

$$v = \sqrt{gL\left(1 - \frac{1}{\sqrt{2}}\right)}$$

Substitute numerical values and evaluate *v*:

$$v = \sqrt{(9.81\,\text{m/s}^2)L\left(1-\frac{1}{\sqrt{2}}\right)}$$

$$= \boxed{(1.70\,\text{m}^{1/2}/\text{s})\sqrt{L}}$$

Chapter 9
Rotation

Conceptual Problems

***1** •

Determine the Concept Because r is greater for the point on the rim, it moves the greater distance. Both turn through the same angle. Because r is greater for the point on the rim, it has the greater speed. Both have the same angular velocity. Both have zero tangential acceleration. Both have zero angular acceleration. Because r is greater for the point on the rim, it has the greater centripetal acceleration.

2 •

(*a*) False. Angular velocity has the dimensions $\left[\frac{1}{T}\right]$ whereas linear velocity has dimensions $\left[\frac{L}{T}\right]$.

(*b*) True. The angular velocity of all points on the wheel is $d\theta/dt$.

(*c*) True. The angular acceleration of all points on the wheel is $d\omega/dt$.

3 ••

Picture the Problem The constant-acceleration equation that relates the given variables is $\omega^2 = \omega_0^2 + 2\alpha\Delta\theta$. We can set up a proportion to determine the number of revolutions required to double ω and then subtract to find the number of additional revolutions to accelerate the disk to an angular speed of 2ω.

Using a constant-acceleration equation, relate the initial and final angular velocities to the angular acceleration:

$$\omega^2 = \omega_0^2 + 2\alpha\Delta\theta$$

or, because $\omega_0^2 = 0$,

$$\omega^2 = 2\alpha\Delta\theta$$

Let $\Delta\theta_{10}$ represent the number of revolutions required to reach an angular velocity ω:

$$\omega^2 = 2\alpha\Delta\theta_{10} \qquad (1)$$

Let $\Delta\theta_{2\omega}$ represent the number of revolutions required to reach an angular velocity ω:

$$(2\omega)^2 = 2\alpha\Delta\theta_{2\omega} \qquad (2)$$

Divide equation (2) by equation (1) and solve for $\Delta\theta_{2\omega}$:

$$\Delta\theta_{2\omega} = \frac{(2\omega)^2}{\omega^2}\Delta\theta_{10} = 4\Delta\theta_{10}$$

The number of *additional* revolutions is: $4\Delta\theta_{10} - \Delta\theta_{10} = 3\Delta\theta_{10} = 3(10\,\text{rev}) = 30\,\text{rev}$

and $\boxed{(c)\text{ is correct.}}$

***4 •**

Determine the Concept Torque has the dimension $\left[\frac{ML^2}{T^2}\right]$.

(*a*) Impulse has the dimension $\left[\frac{ML}{T}\right]$.

(*b*) Energy has the dimension $\left[\frac{ML^2}{T^2}\right]$. $\boxed{(b)\text{ is correct.}}$

(*c*) Momentum has the dimension $\left[\frac{ML}{T}\right]$.

5 •

Determine the Concept The moment of inertia of an object is the product of a constant that is characteristic of the object's distribution of matter, the mass of the object, and the square of the distance from the object's center of mass to the axis about which the object is rotating. Because both (*b*) and (*c*) are correct $\boxed{(d)\text{ is correct.}}$

***6 •**

Determine the Concept Yes. A net torque is required to *change* the rotational state of an object. In the absence of a net torque an object continues in whatever state of rotational motion it was at the instant the net torque became zero.

7 •

Determine the Concept No. A net torque is required to *change* the rotational state of an object. A net torque may decrease the angular speed of an object. All we can say for sure is that a net torque will *change* the angular speed of an object.

8 •

(*a*) False. The net torque acting on an object determines the angular acceleration of the object. At any given instant, the angular velocity may have any value including zero.

(*b*) True. The moment of inertia of a body is *always* dependent on one's choice of an axis of rotation.

(*c*) False. The moment of inertia of an object is the product of a constant that is characteristic of the object's distribution of matter, the mass of the object, and the square of the distance from the object's center of mass to the axis about which the object is rotating.

9 •

Determine the Concept The angular acceleration of a rotating object is proportional to the *net* torque acting on it. The net torque is the product of the tangential force and its lever arm.

Express the angular acceleration of the disk as a function of the net torque acting on it:

$$\alpha = \frac{\tau_{\text{net}}}{I} = \frac{Fd}{I} = \frac{F}{I}d$$

i.e., $\alpha \propto d$

Because $\alpha \propto d$, doubling d will double the angular acceleration.

$\boxed{(b)\text{ is correct.}}$

***10** •

Determine the Concept From the parallel-axis theorem we know that $I = I_{\text{cm}} + Mh^2$, where I_{cm} is the moment of inertia of the object with respect to an axis through its center of mass, M is the mass of the object, and h is the distance between the parallel axes. Therefore, I is always greater than I_{cm} by Mh^2. $\boxed{(d)\text{ is correct.}}$

11 •

Determine the Concept The power delivered by the constant torque is the product of the torque and the angular velocity of the merry-go-round. Because the constant torque causes the merry-go-round to accelerate, neither the power input nor the angular velocity of the merry-go-round is constant. $\boxed{(b)\text{ is correct.}}$

12 •

Determine the Concept Let's make the simplifying assumption that the object and the surface do not deform when they come into contact, i.e., we'll assume that the system is rigid. A force does no work if and only if it is perpendicular to the velocity of an object, and exerts no torque on an extended object if and only if it's directed toward the center of the object. Because neither of these conditions is satisfied, the statement is *false*.

13 •

Determine the Concept For a given applied force, this increases the torque about the hinges of the door, which increases the door's angular acceleration, leading to the door being opened more quickly. It is clear that putting the knob far from the hinges means that the door can be opened with less effort (force). However, it also means that the hand on the knob must move through the greatest distance to open the door, so it may not be the quickest way to open the door. Also, if the knob were at the center of the door, you would have to walk around the door after opening it, assuming the door is opening toward you.

***14 •**

Determine the Concept If the wheel is rolling without slipping, a point at the top of the wheel moves with a speed twice that of the center of mass of the wheel, but the bottom of the wheel is momentarily at rest. $\boxed{(c)\text{ is correct.}}$

15 ••

Picture the Problem The kinetic energies of both objects is the sum of their translational and rotational kinetic energies. Their speed dependence will differ due to the differences in their moments of inertia. We can express the total kinetic of both objects and equate them to decide which of their translational speeds is greater.

Express the kinetic energy of the cylinder:

$$K_{\text{cyl}} = \tfrac{1}{2}I_{\text{cyl}}\omega_{\text{cyl}}^2 + \tfrac{1}{2}mv_{\text{cyl}}^2 = \tfrac{1}{2}\left(\tfrac{1}{2}mr^2\right)\frac{v_{\text{cyl}}^2}{r^2} + \tfrac{1}{2}mv_{\text{cyl}}^2 = \tfrac{3}{4}mv_{\text{cyl}}^2$$

Express the kinetic energy of the sphere:

$$K_{\text{sph}} = \tfrac{1}{2}I_{\text{sph}}\omega_{\text{sphl}}^2 + \tfrac{1}{2}mv_{\text{sph}}^2 = \tfrac{1}{2}\left(\tfrac{2}{5}mr^2\right)\frac{v_{\text{sph}}^2}{r^2} + \tfrac{1}{2}mv_{\text{sph}}^2 = \tfrac{7}{10}mv_{\text{sph}}^2$$

Equate the kinetic energies and simplify to obtain:

$$v_{\text{cyl}} = \sqrt{\tfrac{14}{15}}v_{\text{sph}} < v_{\text{sph}}$$

and $\boxed{(b)\text{ is correct.}}$

***16 •**

Determine the Concept You could spin the pipes about their center. The one which is easier to spin has its mass concentrated closer to the center of mass and, hence, has a smaller moment of inertia.

17 ••

Picture the Problem Because the coin and the ring begin from the same elevation, they will have the same kinetic energy at the bottom of the incline. The kinetic energies of both objects is the sum of their translational and rotational kinetic energies. Their speed dependence will differ due to the differences in their moments of inertia. We can express the total kinetic of both objects and equate them to their common potential energy loss to decide which of their translational speeds is greater at the bottom of the incline.

Express the kinetic energy of the coin at the bottom of the incline:

$$K_{\text{coin}} = \tfrac{1}{2} I_{\text{cyl}} \omega_{\text{coin}}^2 + \tfrac{1}{2} m_{\text{coin}} v_{\text{coin}}^2 = \tfrac{1}{2}\left(\tfrac{1}{2} m_{\text{coin}} r^2\right)\frac{v_{\text{coin}}^2}{r^2} + \tfrac{1}{2} m_{\text{coin}} v_{\text{coin}}^2 = \tfrac{3}{4} m_{\text{coin}} v_{\text{coin}}^2$$

Express the kinetic energy of the ring at the bottom of the incline:

$$K_{\text{ring}} = \tfrac{1}{2} I_{\text{ring}} \omega_{\text{ring}}^2 + \tfrac{1}{2} m_{\text{ring}} v_{\text{ring}}^2 = \tfrac{1}{2}\left(m_{\text{ring}} r^2\right)\frac{v_{\text{ring}}^2}{r^2} + \tfrac{1}{2} m_{\text{ring}} v_{\text{ring}}^2 = m_{\text{ring}} v_{\text{ring}}^2$$

Equate the kinetic of the coin to its change in potential energy as it rolled down the incline and solve for v_{coin}:

$$\tfrac{3}{4} m_{\text{coin}} v_{\text{coin}}^2 = m_{\text{coin}} gh$$

and

$$v_{\text{coin}}^2 = \tfrac{4}{3} gh$$

Equate the kinetic of the ring to its change in potential energy as it rolled down the incline and solve for v_{ring}:

$$m_{\text{ring}} v_{\text{ring}}^2 = m_{\text{ring}} gh$$

and

$$v_{\text{ring}}^2 = gh$$

Therefore, $v_{\text{coin}} > v_{\text{ring}}$ and (b) is correct.

18 ••

Picture the Problem We can use the definitions of the translational and rotational kinetic energies of the hoop and the moment of inertia of a hoop (ring) to express and compare the kinetic energies.

Express the translational kinetic energy of the hoop:

$$K_{\text{trans}} = \tfrac{1}{2} mv^2$$

Express the rotational kinetic energy of the hoop:

$$K_{\text{rot}} = \tfrac{1}{2} I_{\text{hoop}} \omega^2 = \tfrac{1}{2}\left(mr^2\right)\frac{v^2}{r^2} = \tfrac{1}{2} mv^2$$

Therefore, the translational and rotational kinetic energies are the same and (c) is correct.

19 ••

Picture the Problem We can use the definitions of the translational and rotational kinetic energies of the disk and the moment of inertia of a disk (cylinder) to express and compare the kinetic energies.

Express the translational kinetic energy of the disk:

$$K_{trans} = \tfrac{1}{2}mv^2$$

Express the rotational kinetic energy of the disk:

$$K_{rot} = \tfrac{1}{2}I_{hoop}\omega^2 = \tfrac{1}{2}\left(\tfrac{1}{2}mr^2\right)\frac{v^2}{r^2} = \tfrac{1}{4}mv^2$$

Therefore, the translational kinetic energy is greater and $\boxed{(a)\text{ is correct.}}$

20 ••

Picture the Problem Let us assume that $f \neq 0$ and acts along the direction of motion. Now consider the acceleration of the center of mass and the angular acceleration about the point of contact with the plane. Because $F_{net} \neq 0$, $a_{cm} \neq 0$. However, $\tau = 0$ because $\ell = 0$, so $\alpha = 0$. But $\alpha = 0$ is not consistent with $a_{cm} \neq 0$. Consequently, $f = 0$.

21 •

Determine the Concept True. If the sphere is slipping, then there is kinetic friction which dissipates the mechanical energy of the sphere.

22 •

Determine the Concept Because the ball is struck high enough to have topspin, the frictional force is forward; reducing ω until the nonslip condition is satisfied.

$\boxed{(a)\text{ is correct.}}$

Estimation and Approximation

23 ••

Picture the Problem Assume the wheels are hoops, i.e., neglect the mass of the spokes, and express the total kinetic energy of the bicycle and rider. Let M represent the mass of the rider, m the mass of the bicycle, m_w the mass of each bicycle wheel, and r the radius of the wheels.

Express the ratio of the kinetic energy associated with the rotation of the wheels to that associated with the total kinetic energy of the bicycle and rider:

$$\frac{K_{rot}}{K_{tot}} = \frac{K_{rot}}{K_{trans} + K_{rot}} \quad (1)$$

Express the translational kinetic energy of the bicycle and rider:

$$K_{\text{trans}} = K_{\text{bicycle}} + K_{\text{rider}} = \tfrac{1}{2}mv^2 + \tfrac{1}{2}Mv^2$$

Express the rotational kinetic energy of the bicycle wheels:

$$K_{\text{rot}} = 2K_{\text{rot, 1 wheel}} = 2\left(\tfrac{1}{2}I_{\text{w}}\omega^2\right) = \left(m_{\text{w}}r^2\right)\frac{v^2}{r^2} = m_{\text{w}}v^2$$

Substitute in equation (1) to obtain:

$$\frac{K_{\text{rot}}}{K_{\text{tot}}} = \frac{m_{\text{w}}v^2}{\tfrac{1}{2}mv^2 + \tfrac{1}{2}Mv^2 + m_{\text{w}}v^2} = \frac{m_{\text{w}}}{\tfrac{1}{2}m + \tfrac{1}{2}M + m_{\text{w}}} = \frac{2}{2 + \dfrac{m+M}{m_{\text{w}}}}$$

Substitute numerical values and evaluate $K_{\text{rot}}/K_{\text{tot}}$:

$$\frac{K_{\text{rot}}}{K_{\text{tot}}} = \frac{2}{2 + \dfrac{14\,\text{kg} + 38\,\text{kg}}{3\,\text{kg}}} = \boxed{10.3\,\%}$$

24 ••

Picture the Problem We can apply the definition of angular velocity to find the angular orientation of the slice of toast when it has fallen a distance of 0.5 m from the edge of the table. We can then interpret the orientation of the toast to decide whether it lands jelly-side up or down.

Relate the angular orientation θ of the toast to its initial angular orientation, its angular velocity ω, and time of fall Δt:

$$\theta = \theta_0 + \omega\Delta t \qquad (1)$$

Use the equation given in the problem statement to find the angular velocity corresponding to this length of toast:

$$\omega = 0.956\sqrt{\frac{9.81\,\text{m/s}^2}{0.1\,\text{m}}} = 9.47\,\text{rad/s}$$

Using a constant-acceleration equation, relate the distance the toast falls Δy to its time of fall Δt:

$$\Delta y = v_{0y}\Delta t + \tfrac{1}{2}a_y(\Delta t)^2$$

or, because $v_{0y} = 0$ and $a_y = g$,

$$\Delta y = \tfrac{1}{2}g(\Delta t)^2$$

Solve for Δt:

$$\Delta t = \sqrt{\frac{2\Delta y}{g}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \sqrt{\frac{2(0.5\,\text{m})}{9.81\,\text{m/s}^2}} = 0.319\,\text{s}$$

$\frac{(v_f')^2}{2gL} + \cos\theta_0$ Substitute in equation (1) to find θ:

$$\theta = \frac{\pi}{6} + (9.47\,\text{rad/s})(0.319\,\text{s})$$
$$= 3.54\,\text{rad} \times \frac{180°}{\pi\,\text{rad}} = 203°$$

The orientation of the slice of toast will therefore be at an angle of 203° with respect to the ground, i.e. with the jelly-side down.

***25 ••**

Picture the Problem Assume that the mass of an average adult male is about 80 kg, and that we can model his body when he is standing straight up with his arms at his sides as a cylinder. From experience in men's clothing stores, a man's average waist circumference seems to be about 34 inches, and the average chest circumference about 42 inches. We'll also assume that about 20% of the body's mass is in the two arms, and each has a length L = 1 m, so that each arm has a mass of about m = 8 kg.

Letting I_{out} represent his moment of inertia with his arms straight out and I_{in} his moment of inertia with his arms at his side, the ratio of these two moments of inertia is:

$$\frac{I_{out}}{I_{in}} = \frac{I_{body} + I_{arms}}{I_{in}} \qquad (1)$$

Express the moment of inertia of the "man as a cylinder":

$$I_{in} = \tfrac{1}{2}MR^2$$

Express the moment of inertia of his arms:

$$I_{arms} = 2\left(\tfrac{1}{3}\right)mL^2$$

Express the moment of inertia of his body-less-arms:

$$I_{body} = \tfrac{1}{2}(M - m)R^2$$

Substitute in equation (1) to obtain:

$$\frac{I_{out}}{I_{in}} = \frac{\tfrac{1}{2}(M - m)R^2 + 2\left(\tfrac{1}{3}\right)mL^2}{\tfrac{1}{2}MR^2}$$

Assume the circumference of the cylinder to be the average of the average waist circumference and the average chest circumference:

$$c_{av} = \frac{34\,\text{in} + 42\,\text{in}}{2} = 38\,\text{in}$$

Find the radius of a circle whose circumference is 38 in:

$$R = \frac{c_{av}}{2\pi} = \frac{38\,\text{in} \times \frac{2.54\,\text{cm}}{\text{in}} \times \frac{1\,\text{m}}{100\,\text{cm}}}{2\pi}$$
$$= 0.154\,\text{m}$$

Substitute numerical values and evaluate I_{out}/I_{in}:

$$\frac{I_{out}}{I_{in}} = \frac{\frac{1}{2}(80\,\text{kg} - 16\,\text{kg})(0.154\,\text{m})^2 + \frac{2}{3}(8\,\text{kg})(1\,\text{m})^2}{\frac{1}{2}(80\,\text{kg})(0.154\,\text{m})^2} = \boxed{6.42}$$

Angular Velocity and Angular Acceleration

26 •

Picture the Problem The tangential and angular velocities of a particle moving in a circle are directly proportional. The number of revolutions made by the particle in a given time interval is proportional to both the time interval and its angular speed.

(*a*) Relate the angular velocity of the particle to its speed along the circumference of the circle:

$$v = r\omega$$

Solve for and evaluate ω:

$$\omega = \frac{v}{r} = \frac{25\,\text{m/s}}{90\,\text{m}} = \boxed{0.278\,\text{rad/s}}$$

(*b*) Using a constant-acceleration equation, relate the number of revolutions made by the particle in a given time interval to its angular velocity:

$$\Delta\theta = \omega\Delta t = \left(0.278\frac{\text{rad}}{\text{s}}\right)(30\,\text{s})\left(\frac{1\,\text{rev}}{2\pi\,\text{rad}}\right)$$

$$= \boxed{1.33\,\text{rev}}$$

27 •

Picture the Problem Because the angular acceleration is constant; we can find the various physical quantities called for in this problem by using constant-acceleration equations.

(*a*) Using a constant-acceleration equation, relate the angular velocity of the wheel to its angular acceleration and the time it has been accelerating:

$$\omega = \omega_0 + \alpha\Delta t$$

or, when $\omega_0 = 0$,

$$\omega = \alpha\Delta t$$

Evaluate ω when $\Delta t = 6$ s:

$$\omega = \left(2.6\,\text{rad/s}^2\right)(6\,\text{s}) = \boxed{15.6\,\text{rad/s}}$$

(*b*) Using another constant-acceleration equation, relate the angular displacement to the wheel's angular acceleration and the time it

$$\Delta\theta = \omega_0\Delta t + \tfrac{1}{2}\alpha(\Delta t)^2$$

or, when $\omega_0 = 0$,

$$\Delta\theta = \tfrac{1}{2}\alpha(\Delta t)^2$$

has been accelerating:

Evaluate $\Delta\theta$ when Δt = 6 s:

$$\Delta\theta(6\,\text{s}) = \tfrac{1}{2}(2.6\,\text{rad/s}^2)(6\,\text{s})^2 = \boxed{46.8\,\text{rad}}$$

(*c*) Convert $\Delta\theta(6\,\text{s})$ from rad to revolutions:

$$\Delta\theta(6\,\text{s}) = 46.8\,\text{rad} \times \frac{1\,\text{rev}}{2\pi\,\text{rad}} = \boxed{7.45\,\text{rev}}$$

(*d*) Relate the angular velocity of the particle to its tangential speed and evaluate the latter when Δt = 6 s:

$$v = r\omega = (0.3\,\text{m})(15.6\,\text{rad/s}) = \boxed{4.68\,\text{m/s}}$$

Relate the resultant acceleration of the point to its tangential and centripetal accelerations when Δt = 6 s:

$$a = \sqrt{a_{\text{t}}^2 + a_{\text{c}}^2} = \sqrt{(r\alpha)^2 + (r\omega^2)^2} = r\sqrt{\alpha^2 + \omega^4}$$

Substitute numerical values and evaluate a:

$$a = (0.3\,\text{m})\sqrt{(2.6\,\text{rad/s}^2)^2 + (15.6\,\text{rad/s})^4} = \boxed{73.0\,\text{m/s}^2}$$

***28** •

Picture the Problem Because we're assuming constant angular acceleration; we can find the various physical quantities called for in this problem by using constant-acceleration equations.

(*a*) Using its definition, express the angular acceleration of the turntable:

$$\alpha = \frac{\Delta\omega}{\Delta t} = \frac{\omega - \omega_0}{\Delta t}$$

Substitute numerical values and evaluate α:

$$\alpha = \frac{0 - 33\tfrac{1}{3}\dfrac{\text{rev}}{\text{min}} \times \dfrac{2\pi\,\text{rad}}{\text{rev}} \times \dfrac{1\,\text{min}}{60\,\text{s}}}{26\,\text{s}} = \boxed{0.134\,\text{rad/s}^2}$$

(*b*) Because the angular acceleration is constant, the average angular velocity is the average of its initial and final values:

$$\omega_{av} = \frac{\omega_0 + \omega}{2}$$

$$= \frac{33\frac{1}{3}\frac{\text{rev}}{\text{min}} \times \frac{2\pi\,\text{rad}}{\text{rev}} \times \frac{1\,\text{min}}{60\,\text{s}}}{2}$$

$$= \boxed{1.75\,\text{rad/s}}$$

(*c*) Using the definition of ω_{av}, find the number or revolutions the turntable makes before stopping:

$$\Delta\theta = \omega_{av}\Delta t = (1.75\,\text{rad/s})(26\,\text{s})$$

$$= 45.5\,\text{rad} \times \frac{1\,\text{rev}}{2\pi\,\text{rad}} = \boxed{7.24\,\text{rev}}$$

29 •

Picture the Problem Because the angular acceleration of the disk is constant, we can use a constant-acceleration equation to relate its angular velocity to its acceleration and the time it has been accelerating. We can find the tangential and centripetal accelerations from their relationships to the angular velocity and angular acceleration of the disk.

(*a*) Using a constant-acceleration equation, relate the angular velocity of the disk to its angular acceleration and time during which it has been accelerating:

$$\omega = \omega_0 + \alpha\,\Delta t$$

or, because $\omega_0 = 0$,

$$\omega = \alpha\,\Delta t$$

Evaluate ω when $t = 5$ s:

$$\omega(5\,\text{s}) = (8\,\text{rad/s}^2)(5\,\text{s}) = \boxed{40.0\,\text{rad/s}}$$

(*b*) Express a_t in terms of α:

$$a_t = r\alpha$$

Evaluate a_t when $t = 5$ s:

$$a_t(5\,\text{s}) = (0.12\,\text{m})(8\,\text{rad/s}^2)$$

$$= \boxed{0.960\,\text{m/s}^2}$$

Express a_c in terms of ω:

$$a_c = r\omega^2$$

Evaluate a_c when $t = 5$ s:

$$a_c(5\,\text{s}) = (0.12\,\text{m})(40.0\,\text{rad/s})^2$$

$$= \boxed{192\,\text{m/s}^2}$$

30 •

Picture the Problem We can find the angular velocity of the Ferris wheel from its definition and the linear speed and centripetal acceleration of the passenger from the relationships between those quantities and the angular velocity of the Ferris wheel.

(*a*) Find ω from its definition:

$$\omega = \frac{\Delta\theta}{\Delta t} = \frac{2\pi\,\text{rad}}{27\,\text{s}} = \boxed{0.233\,\text{rad/s}}$$

(*b*) Find the linear speed of the passenger from his/her angular speed:

$$v = r\omega = (12\,\text{m})(0.233\,\text{rad/s}) = \boxed{2.79\,\text{m/s}}$$

Find the passenger's centripetal acceleration from his/her angular velocity:

$$a_c = r\omega^2 = (12\,\text{m})(0.233\,\text{rad/s})^2 = \boxed{0.651\,\text{m/s}^2}$$

31 •

Picture the Problem Because the angular acceleration of the wheels is constant, we can use constant-acceleration equations in rotational form to find their angular acceleration and their angular velocity at any given time.

(*a*) Using a constant-acceleration equation, relate the angular displacement of the wheel to its angular acceleration and the time it has been accelerating:

$$\Delta\theta = \omega_0\Delta t + \tfrac{1}{2}\alpha(\Delta t)^2$$

or, because $\omega_0 = 0$,

$$\Delta\theta = \tfrac{1}{2}\alpha(\Delta t)^2$$

Solve for α:

$$\alpha = \frac{2\Delta\theta}{(\Delta t)^2}$$

Substitute numerical values and evaluate α:

$$\alpha = \frac{2(3\,\text{rev})\left(\frac{2\pi\,\text{rad}}{\text{rev}}\right)}{(8\,\text{s})^2} = \boxed{0.589\,\text{rad/s}^2}$$

(*b*) Using a constant-acceleration equation, relate the angular velocity of the wheel to its angular acceleration and the time it has been accelerating:

$$\omega = \omega_0 + \alpha\Delta t$$

or, when $\omega_0 = 0$,

$$\omega = \alpha\Delta t$$

Evaluate ω when $\Delta t = 8$ s:

$$\omega(8\,\text{s}) = (0.589\,\text{rad/s}^2)(8\,\text{s}) = \boxed{4.71\,\text{rad/s}}$$

32 •

Picture the Problem The earth rotates through 2π radians every 24 hours.

Find ω using its definition:

$$\omega \equiv \frac{\Delta\theta}{\Delta t} = \frac{2\pi\text{ rad}}{24\text{ h}\times\frac{3600\text{ s}}{\text{h}}}$$

$$= \boxed{7.27\times10^{-5}\text{ rad/s}}$$

33 •

Picture the Problem When the angular acceleration of a wheel is constant, its average angular velocity is the average of its initial and final angular velocities. We can combine this relationship with the always applicable definition of angular velocity to find the initial angular velocity of the wheel.

Express the average angular velocity of the wheel in terms of its initial and final angular speeds:

$$\omega_{\text{av}} = \frac{\omega_0 + \omega}{2}$$

or, because $\omega = 0$,

$$\omega_{\text{av}} = \tfrac{1}{2}\omega_0$$

Express the definition of the average angular velocity of the wheel:

$$\omega_{\text{av}} \equiv \frac{\Delta\theta}{\Delta t}$$

Equate these two expressions and solve for ω_0:

$$\omega_0 = \frac{2\Delta\theta}{\Delta t} = \frac{2(5\text{ rad})}{2.8\text{ s}} = 3.57\text{ s and}$$

$$\boxed{(d)\text{ is correct.}}$$

34 •

Picture the Problem The tangential and angular accelerations of the wheel are directly proportional to each other with the radius of the wheel as the proportionality constant. Provided there is no slippage, the acceleration of a point on the rim of the wheel is the same as the acceleration of the bicycle. We can use its defining equation to determine the acceleration of the bicycle.

Relate the tangential acceleration of a point on the wheel (equal to the acceleration of the bicycle) to the wheel's angular acceleration and solve for its angular acceleration:

$$a = a_{\text{t}} = r\alpha$$

and

$$\alpha = \frac{a}{r}$$

Use its definition to express the acceleration of the wheel:

$$a=\frac{\Delta v}{\Delta t}=\frac{v-v_0}{\Delta t}$$

or, because $v_0 = 0$,

$$a=\frac{v}{\Delta t}$$

Substitute in the expression for α to obtain:

$$\alpha=\frac{v}{r\Delta t}$$

Substitute numerical values and evaluate α:

$$\alpha=\frac{\left(24\frac{\text{km}}{\text{h}}\right)\left(\frac{1\,\text{h}}{3600\,\text{s}}\right)\left(\frac{1000\,\text{m}}{\text{km}}\right)}{(0.6\,\text{m})(14.0\,\text{s})}=\boxed{0.794\,\text{rad/s}^2}$$

***35 ••**

Picture the Problem The two tapes will have the same tangential and angular velocities when the two reels are the same size, i.e., have the same area. We can calculate the tangential speed of the tape from its length and running time and relate the angular velocity to the constant tangential speed and the radius of the reels when they are turning with the same angular velocity.

Relate the angular velocity of the tape to its tangential speed:

$$\omega=\frac{v}{r} \qquad (1)$$

Letting R_f represent the outer radius of the reel when the reels have the same area, express the condition that they have the same speed:

$$\pi R_\text{f}^2-\pi r^2=\tfrac{1}{2}\left(\pi R^2-\pi r^2\right)$$

Solve for R_f:

$$R_\text{f}=\sqrt{\frac{R^2+r^2}{2}}$$

Substitute numerical values and evaluate R_f:

$$R_\text{f}=\sqrt{\frac{(45\,\text{mm})^2+(12\,\text{mm})^2}{2}}=32.9\,\text{mm}$$

Find the tangential speed of the tape from its length and running time:

$$v=\frac{L}{\Delta t}=\frac{246\,\text{m}\times\frac{100\,\text{cm}}{\text{m}}}{2\,\text{h}\times\frac{3600\,\text{s}}{\text{h}}}=3.42\,\text{cm/s}$$

Substitute in equation (1) and evaluate ω:

$$\omega = \frac{v}{R_f} = \frac{3.42\,\text{cm/s}}{32.9\,\text{mm}\times\frac{1\,\text{cm}}{10\,\text{mm}}} = \boxed{1.04\,\text{rad/s}}$$

Convert 1.04 rad/s to rev/min:

$$1.04\,\text{rad/s} = 1.04\frac{\text{rad}}{\text{s}}\times\frac{1\,\text{rev}}{2\pi\,\text{rad}}\times\frac{60\,\text{s}}{\text{min}} = \boxed{9.93\,\text{rev/min}}$$

Torque, Moment of Inertia, and Newton's Second Law for Rotation

36 •

Picture the Problem The force that the woman exerts through her axe, because it does not act at the axis of rotation, produces a net torque that changes (decreases) the angular velocity of the grindstone.

(*a*) From the definition of angular acceleration we have:

$$\alpha = \frac{\Delta\omega}{\Delta t} = \frac{\omega - \omega_0}{\Delta t}$$

or, because $\omega = 0$,

$$\alpha = \frac{-\omega_0}{\Delta t}$$

Substitute numerical values and evaluate α:

$$\alpha = -\frac{730\frac{\text{rev}}{\text{min}}\times\frac{2\pi\,\text{rad}}{\text{rev}}\times\frac{1\,\text{min}}{60\,\text{s}}}{9\,\text{s}} = \boxed{-8.49\,\text{rad/s}^2}$$

where the minus sign means that the grindstone is slowing down.

(*b*) Use Newton's 2nd law in rotational form to relate the angular acceleration of the grindstone to the net torque slowing it:

$$\tau_{\text{net}} = I\alpha$$

Express the moment of inertia of disk with respect to its axis of rotation:

$$I = \tfrac{1}{2}MR^2$$

Substitute to obtain: $\tau_{net} = \frac{1}{2}MR\alpha$

Substitute numerical values and evaluate τ_{net}:

$$\tau_{net} = \frac{1}{2}(1.7\,\text{kg})(0.08\,\text{m})^2(8.49\,\text{rad/s}^2) = \boxed{0.0462\,\text{N}\cdot\text{m}}$$

***37 •**

Picture the Problem We can find the torque exerted by the 17-N force from the definition of torque. The angular acceleration resulting from this torque is related to the torque through Newton's 2nd law in rotational form. Once we know the angular acceleration, we can find the angular velocity of the cylinder as a function of time.

(*a*) Calculate the torque from its definition:

$$\tau = F\ell = (17\,\text{N})(0.11\,\text{m}) = \boxed{1.87\,\text{N}\cdot\text{m}}$$

(*b*) Use Newton's 2nd law in rotational form to relate the acceleration resulting from this torque to the torque:

$$\alpha = \frac{\tau}{I}$$

Express the moment of inertia of the cylinder with respect to its axis of rotation:

$$I = \frac{1}{2}MR^2$$

Substitute to obtain:

$$\alpha = \frac{2\tau}{MR^2}$$

Substitute numerical values and evaluate α:

$$\alpha = \frac{2(1.87\,\text{N}\cdot\text{m})}{(2.5\,\text{kg})(0.11\,\text{m})^2} = \boxed{124\,\text{rad/s}^2}$$

(*c*) Using a constant-acceleration equation, express the angular velocity of the cylinder as a function of time:

$$\omega = \omega_0 + \alpha t$$

or, because $\omega_0 = 0$,

$$\omega = \alpha t$$

Evaluate ω (5 s):

$$\omega(5\,\text{s}) = (124\,\text{rad/s}^2)(5\,\text{s}) = \boxed{620\,\text{rad/s}}$$

38 ••

Picture the Problem We can find the angular acceleration of the wheel from its definition and the moment of inertia of the wheel from Newton's 2nd law.

(*a*) Express the moment of inertia of the wheel in terms of the angular acceleration produced by the applied torque:

$$I = \frac{\tau}{\alpha}$$

Find the angular acceleration of the wheel:

$$\alpha = \frac{\Delta\omega}{\Delta t} = \frac{600\,\frac{\text{rev}}{\text{min}} \times \frac{2\pi\,\text{rad}}{\text{rev}} \times \frac{1\,\text{min}}{60\,\text{s}}}{20\,\text{s}}$$
$$= 3.14\,\text{rad/s}^2$$

Substitute and evaluate *I*:

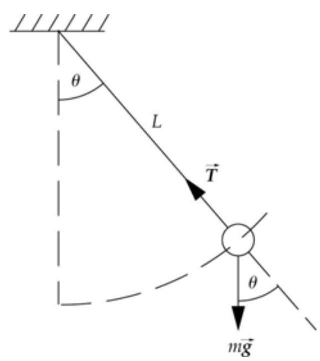
$$I = \frac{50\,\text{N}\cdot\text{m}}{3.14\,\text{rad/s}^2} = \boxed{15.9\,\text{kg}\cdot\text{m}^2}$$

(*b*) Because the wheel takes 120 s to slow to a stop (it took 20 s to acquire an angular velocity of 600 rev/min) and its angular acceleration is directly proportional to the accelerating torque:

$$\tau_{\text{fr}} = \tfrac{1}{6}\tau = \tfrac{1}{6}(50\,\text{N}\cdot\text{m}) = \boxed{8.33\,\text{N}\cdot\text{m}}$$

39 ••

Picture the Problem The pendulum and the forces acting on it are shown in the free-body diagram. Note that the tension in the string is radial, and so exerts no tangential force on the ball. We can use Newton's 2nd law in both translational and rotational form to find the tangential component of the acceleration of the bob.



(*a*) Referring to the FBD, express the component of $m\vec{g}$ that is tangent to the circular path of the bob:

$$F_{\text{t}} = mg\sin\theta$$

Use Newton's 2nd law to express the tangential acceleration of the bob:

$$a_{\text{t}} = \frac{F_{\text{t}}}{m} = \boxed{g\sin\theta}$$

(*b*) Noting that, because the line-of-action of the tension passes through the pendulum's pivot point, its lever arm is zero and the net torque is due

$$\sum \tau_{\text{pivot point}} = \boxed{mgL\sin\theta}$$

to the weight of the bob, sum the torques about the pivot point to obtain:

$$\tau_{\text{net}} = mgL\sin\theta = I\alpha$$

(*c*) Use Newton's 2nd law in rotational form to relate the angular acceleration of the pendulum to the net torque acting on it:

Solve for α to obtain:

$$\alpha = \frac{mgL\sin\theta}{I}$$

Express the moment of inertia of the bob with respect to the pivot point:

$$I = mL^2$$

Substitute to obtain:

$$\alpha = \frac{mgL\sin\theta}{mL^2} = \frac{g\sin\theta}{L}$$

Relate α to a_t:

$$a_t = r\alpha = L\left(\frac{g\sin\theta}{L}\right) = \boxed{g\sin\theta}$$

***40** •••

Picture the Problem We can express the velocity of the center of mass of the rod in terms of its distance from the pivot point and the angular velocity of the rod. We can find the angular velocity of the rod by using Newton's 2nd law to find its angular acceleration and then a constant-acceleration equation that relates ω to α. We'll use the impulse-momentum relationship to derive the expression for the force delivered to the rod by the pivot. Finally, the location of the *center of percussion* of the rod will be verified by setting the force exerted by the pivot to zero.

(*a*) Relate the velocity of the center of mass to its distance from the pivot point:

$$v_{\text{cm}} = \frac{L}{2}\omega \qquad (1)$$

Express the torque due to F_0:

$$\tau = F_0 x = I_{\text{pivot}}\alpha$$

Solve for α:

$$\alpha = \frac{F_0 x}{I_{\text{pivot}}}$$

Express the moment of inertia of the rod with respect to an axis through

$$I_{\text{pivot}} = \tfrac{1}{3}ML^2$$

its pivot point:

Substitute to obtain:

$$\alpha = \frac{3F_0 x}{ML^2}$$

Express the angular velocity of the rod in terms of its angular acceleration:

$$\omega = \alpha\,\Delta t = \frac{3F_0 x\Delta t}{ML^2}$$

Substitute in equation (1) to obtain:

$$v_{\mathrm{cm}} = \boxed{\frac{3F_0 x\Delta t}{2ML}}$$

(*b*) Let I_{P} be the impulse exerted by the pivot on the rod. Then the total impulse (equal to the change in momentum of the rod) exerted on the rod is:

$$I_{\mathrm{P}} + F_0\Delta t = Mv_{\mathrm{cm}}$$

and

$$I_{\mathrm{P}} = Mv_{\mathrm{cm}} - F_0\Delta t$$

Substitute our result from (a) to obtain:

$$I_{\mathrm{P}} = \frac{3F_0 x\Delta t}{2L} - F_0\Delta t = F_0\Delta t\left(\frac{3x}{2L} - 1\right)$$

Because $I_{\mathrm{P}} = F_{\mathrm{P}}\Delta t$:

$$F_{\mathrm{P}} = \boxed{F_0\left(\frac{3x}{2L} - 1\right)}$$

In order for F_{P} to be zero:

$$\frac{3x}{2L} - 1 = 0 \Rightarrow x = \boxed{\frac{2L}{3}}$$

41 •••

Picture the Problem We'll first express the torque exerted by the force of friction on the elemental disk and then integrate this expression to find the torque on the entire disk. We'll use Newton's 2nd law to relate this torque to the angular acceleration of the disk and then to the stopping time for the disk.

(*a*) Express the torque exerted on the elemental disk in terms of the friction force and the distance to the elemental disk:

$$d\tau_{\mathrm{f}} = rdf_{\mathrm{k}} \qquad (1)$$

Using the definition of the coefficient of friction, relate the

$$df_{\mathrm{k}} = \mu_{\mathrm{k}} g dm \qquad (2)$$

force of friction to μ_k and the weight of the circular element:

Letting σ represent the mass per unit area of the disk, express the mass of the circular element:

$$dm = 2\pi r\sigma\, dr \qquad (3)$$

Substitute equations (2) and (3) in (1) to obtain:

$$d\tau_f = 2\pi \mu_k \sigma\, g r^2 dr \qquad (4)$$

Because $\sigma = \dfrac{M}{\pi R^2}$:

$$d\tau_f = \boxed{\frac{2\mu_k M g}{R^2} r^2 dr}$$

(*b*) Integrate $d\tau_f$ to obtain the total torque on the elemental disk:

$$\tau_f = \frac{2\mu_k M g}{R^2}\int_0^R r^2 dr = \boxed{\tfrac{2}{3} MR\mu_k g}$$

(*c*) Relate the disk's stopping time to its angular velocity and acceleration:

$$\Delta t = \frac{\omega}{\alpha}$$

Using Newton's 2nd law, express α in terms of the net torque acting on the disk:

$$\alpha = \frac{\tau_f}{I}$$

The moment of inertia of the disk, with respect to its axis of rotation, is:

$$I = \tfrac{1}{2} MR^2$$

Substitute and simplify to obtain:

$$\Delta t = \boxed{\frac{3R\omega}{4\mu_k g}}$$

Calculating the Moment of Inertia

42 •

Picture the Problem One can find the formula for the moment of inertia of a thin spherical shell in Table 9-1.

The moment of inertia of a thin spherical shell about its diameter is:

$$I = \tfrac{2}{3} MR^2$$

Substitute numerical values and evaluate I:

$$I = \tfrac{2}{3}(0.057\,\text{kg})(0.035\,\text{m})^2 = \boxed{4.66\times10^{-5}\,\text{kg}\cdot\text{m}^2}$$

***43 •**

Picture the Problem The moment of inertia of a system of particles with respect to a given axis is the sum of the products of the mass of each particle and the square of its distance from the given axis.

Use the definition of the moment of inertia of a system of particles to obtain:

$$I = \sum_i m_i r_i^2 = m_1 r_1^2 + m_2 r_2^2 + m_3 r_3^2 + m_4 r_4^2$$

Substitute numerical values and evaluate I:

$$I = (3\,\text{kg})(2\,\text{m})^2 + (4\,\text{kg})\left(2\sqrt{2}\,\text{m}\right)^2 + (4\,\text{kg})(0)^2 + (3\,\text{kg})(2\,\text{m})^2 = \boxed{56.0\,\text{kg}\cdot\text{m}^2}$$

44 •

Picture the Problem Note, from symmetry considerations, that the center of mass of the system is at the intersection of the diagonals connecting the four masses. Thus the distance of each particle from the axis through the center of mass is $\sqrt{2}$ m. According to the parallel-axis theorem, $I = I_{cm} + Mh^2$, where I_{cm} is the moment of inertia of the object with respect to an axis through its center of mass, M is the mass of the object, and h is the distance between the parallel axes.

Express the parallel axis theorem:

$$I = I_{cm} + Mh^2$$

Solve for I_{cm} and substitute from Problem 44:

$$I_{cm} = I - Mh^2 = 56.0\,\text{kg}\cdot\text{m}^2 - (14\,\text{kg})\left(\sqrt{2}\,\text{m}\right)^2 = \boxed{28.0\,\text{kg}\cdot\text{m}^2}$$

Use the definition of the moment of inertia of a system of particles to express I_{cm}:

$$I_{cm} = \sum_i m_i r_i^2 = m_1 r_1^2 + m_2 r_2^2 + m_3 r_3^2 + m_4 r_4^2$$

Substitute numerical values and evaluate I_{cm}:

$$I_{cm} = (3\,\text{kg})\left(\sqrt{2}\,\text{m}\right)^2 + (4\,\text{kg})\left(\sqrt{2}\,\text{m}\right)^2 + (4\,\text{kg})\left(\sqrt{2}\,\text{m}\right)^2 + (3\,\text{kg})\left(\sqrt{2}\,\text{m}\right)^2 = \boxed{28.0\,\text{kg}\cdot\text{m}^2}$$

45 •

Picture the Problem The moment of inertia of a system of particles with respect to a given axis is the sum of the products of the mass of each particle and the square of its distance from the given axis.

(*a*) Apply the definition of the moment of inertia of a system of particles to express I_x:

$$I_x = \sum_{\rm i} m_{\rm i} r_{\rm i}^2 = m_1 r_1^2 + m_2 r_2^2 + m_3 r_3^2 + m_4 r_4^2$$

Substitute numerical values and evaluate I_x:

$$I_x = (3\,\text{kg})(2\,\text{m})^2 + (4\,\text{kg})(2\,\text{m})^2 + (4\,\text{kg})(0) + (3\,\text{kg})(0) = \boxed{28.0\,\text{kg}\cdot\text{m}^2}$$

(*b*) Apply the definition of the moment of inertia of a system of particles to express I_y:

$$I_y = \sum_{\rm i} m_{\rm i} r_{\rm i}^2 = m_1 r_1^2 + m_2 r_2^2 + m_3 r_3^2 + m_4 r_4^2$$

Substitute numerical values and evaluate I_y:

$$I_y = (3\,\text{kg})(0) + (4\,\text{kg})(2\,\text{m})^2 + (4\,\text{kg})(0) + (3\,\text{kg})(2\,\text{m})^2 = \boxed{28.0\,\text{kg}\cdot\text{m}^2}$$

Remarks: We could also use a symmetry argument to conclude that $I_y = I_x$.

46 •

Picture the Problem According to the parallel-axis theorem, $I = I_{\text{cm}} + Mh^2$, where I_{cm} is the moment of inertia of the object with respect to an axis through its center of mass, M is the mass of the object, and h is the distance between the parallel axes.

Use Table 9-1 to find the moment of inertia of a sphere with respect to an axis through its center of mass:

$$I_{\text{cm}} = \tfrac{2}{5} MR^2$$

Express the parallel axis theorem:

$$I = I_{\text{cm}} + Mh^2$$

Substitute for I_{cm} and simplify to obtain:

$$I = \tfrac{2}{5} MR^2 + MR^2 = \boxed{\tfrac{7}{5} MR^2}$$

47 ••

Picture the Problem The moment of inertia of the wagon wheel is the sum of the moments of inertia of the rim and the six spokes.

Express the moment of inertia of the wagon wheel as the sum of the moments of inertia of the rim and the spokes:

$$I_{\text{wheel}} = I_{\text{rim}} + I_{\text{spokes}}$$

Using Table 9-1, find formulas for the moments of inertia of the rim and spokes:

$$I_{\text{rim}} = M_{\text{rim}}R^2$$

and

$$I_{\text{spoke}} = \tfrac{1}{3}M_{\text{spoke}}L^2$$

Substitute to obtain:

$$I_{\text{wheel}} = M_{\text{rim}}R^2 + 6\left(\tfrac{1}{3}M_{\text{spoke}}L^2\right) = M_{\text{rim}}R^2 + 2M_{\text{spoke}}L^2$$

Substitute numerical values and evaluate I_{wheel}:

$$I_{\text{wheel}} = (8\,\text{kg})(0.5\,\text{m})^2 + 2(1.2\,\text{kg})(0.5\,\text{m})^2 = \boxed{2.60\,\text{kg}\cdot\text{m}^2}$$

***48** ••

Picture the Problem The moment of inertia of a system of particles depends on the axis with respect to which it is calculated. Once this choice is made, the moment of inertia is the sum of the products of the mass of each particle and the square of its distance from the chosen axis.

(*a*) Apply the definition of the moment of inertia of a system of particles:

$$I = \sum_{\text{i}} m_{\text{i}}r_{\text{i}}^2 = \boxed{m_1x^2 + m_2(L-x)^2}$$

(*b*) Set the derivative of *I* with respect to *x* equal to zero in order to identify values for *x* that correspond to either maxima or minima:

$$\frac{dI}{dx} = 2m_1x + 2m_2(L-x)(-1) = 2(m_1x + m_2x - m_2L) = 0 \text{ for extrema}$$

If $\frac{dI}{dx} = 0$, then:

$$m_1x + m_2x - m_2L = 0$$

Solve for x:

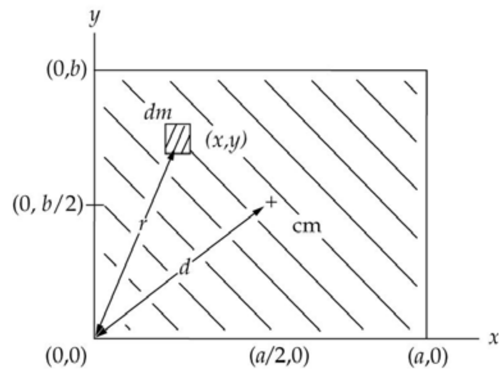
$$x = \frac{m_2 L}{m_1 + m_2}$$

Convince yourself that you've found a minimum by showing that $\frac{d^2 I}{dx^2}$ is positive at this point.

$x = \frac{m_2 L}{m_1 + m_2}$ is, by definition, the distance of the center of mass from m.

49 ••

Picture the Problem Let σ be the mass per unit area of the uniform rectangular plate. Then the elemental unit has mass $dm = \sigma\, dxdy$. Let the corner of the plate through which the axis runs be the origin. The distance of the element whose mass is dm from the corner r is related to the coordinates of dm through the Pythagorean relationship $r^2 = x^2 + y^2$.



(*a*) Express the moment of inertia of the element whose mass is dm with respect to an axis perpendicular to it and passing through one of the corners of the uniform rectangular plate:

$$dI = \sigma\left(x^2 + y^2\right)dxdy$$

Integrate this expression to find I:

$$I = \sigma \int_0^a \int_0^b \left(x^2 + y^2\right)dxdy$$

$$= \tfrac{1}{3}\sigma\left(a^3 b + ab^3\right) = \boxed{\tfrac{1}{3}m\left(a^2 + b^3\right)}$$

(*b*) Letting d represent the distance from the origin to the center of mass of the plate, use the parallel axis theorem to relate the moment of inertia found in (*a*) to the moment of inertia with respect to an axis through the center of mass:

$$I = I_{\text{cm}} + md^2$$

or

$$I_{\text{cm}} = I - md^2 = \tfrac{1}{3}m\left(a^2 + b^2\right) - md^2$$

Using the Pythagorean theorem, relate the distance d to the center of

$$d^2 = \left(\tfrac{1}{2}a\right)^2 + \left(\tfrac{1}{2}b\right)^2 = \tfrac{1}{4}\left(a^2 + b^2\right)$$

mass to the lengths of the sides of the plate:

Substitute for d^2 in the expression for I_{cm} and simplify to obtain:

$$I_{cm} = \tfrac{1}{3}m\left(a^2+b^2\right)-\tfrac{1}{4}m\left(a^2+b^2\right)^2 = \boxed{\tfrac{1}{12}m\left(a^2+b^2\right)}$$

***50 ••**

Picture the Problem Corey will use the point-particle relationship $I_{app}=\sum_i m_i r_i^2 = m_1r_1^2+m_2r_2^2$ for his calculation whereas Tracey's calculation will take into account not only the rod but also the fact that the spheres are not point particles.

(*a*) Using the point-mass approximation and the definition of the moment of inertia of a system of particles, express I_{app}:

$$I_{app}=\sum_i m_i r_i^2 = m_1r_1^2+m_2r_2^2$$

Substitute numerical values and evaluate I_{app}:

$$I_{app}=(0.5\,\text{kg})(0.2\,\text{m})^2+(0.5\,\text{kg})(0.2\,\text{m})^2 = \boxed{0.0400\,\text{kg}\cdot\text{m}^2}$$

Express the moment of inertia of the two spheres and connecting rod system:

$$I = I_{spheres}+I_{rod}$$

Use Table 9-1 to find the moments of inertia of a sphere (with respect to its center of mass) and a rod (with respect to an axis through its center of mass):

$$I_{sphere}=\tfrac{2}{5}M_{sphere}R^2$$

and

$$I_{rod}=\tfrac{1}{12}M_{rod}L^2$$

Because the spheres are not on the axis of rotation, use the parallel axis theorem to express their moment of inertia with respect to the axis of rotation:

$$I_{sphere}=\tfrac{2}{5}M_{sphere}R^2+M_{sphere}h^2$$

where h is the distance from the center of mass of a sphere to the axis of rotation.

Substitute to obtain:

$$I = 2\left\{\tfrac{2}{5}M_{sphere}R^2+M_{sphere}h^2\right\}+\tfrac{1}{12}M_{rod}L^2$$

Substitute numerical values and evaluate I:

$$I = 2\left\{\tfrac{2}{5}(0.5\,\text{kg})(0.05\,\text{m})^2 + (0.5\,\text{kg})(0.2\,\text{m})^2\right\} + \tfrac{1}{12}(0.06\,\text{kg})(0.3\,\text{m})^2$$
$$= \boxed{0.0415\,\text{kg}\cdot\text{m}^2}$$

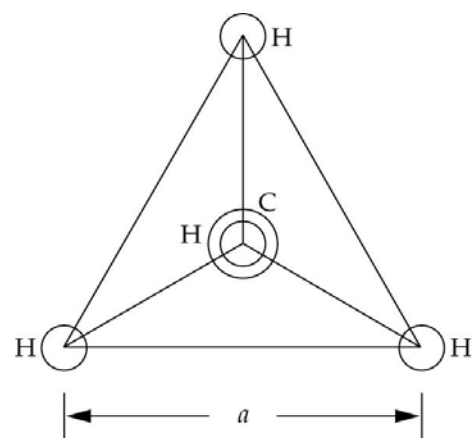
Compare I and I_{app} by taking their ratio:

$$\frac{I_{app}}{I} = \frac{0.0400\,\text{kg}\cdot\text{m}^2}{0.0415\,\text{kg}\cdot\text{m}^2} = \boxed{0.964}$$

(*b*) The rotational inertia would increase because I_{cm} of a hollow sphere is greater than I_{cm} of a solid sphere.

51 ••

Picture the Problem The axis of rotation passes through the center of the base of the tetrahedron. The carbon atom and the hydrogen atom at the apex of the tetrahedron do not contribute to I because the distance of their nuclei from the axis of rotation is zero. From the geometry, the distance of the three H nuclei from the rotation axis is $a/\sqrt{3}$, where a is the length of a side of the tetrahedron.



Apply the definition of the moment of inertia for a system of particles to obtain:

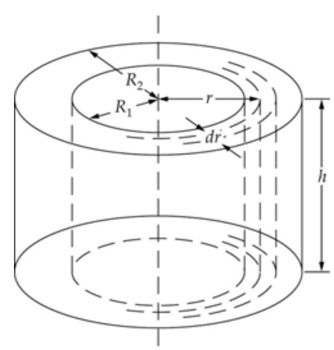
$$I = \sum_i m_i r_i^2 = m_H r_1^2 + m_H r_2^2 + m_H r_3^2$$
$$= 3m_H\left(\frac{a}{\sqrt{3}}\right)^2 = m_H a^2$$

Substitute numerical values and evaluate I:

$$I = (1.67\times10^{-27}\,\text{kg})(0.18\times10^{-9}\,\text{m})^2$$
$$= \boxed{5.41\times10^{-47}\,\text{kg}\cdot\text{m}^2}$$

52 ••

Picture the Problem Let the mass of the element of volume dV be $dm = \rho dV = 2\pi\rho hrdr$ where h is the height of the cylinder. We'll begin by expressing the moment of inertia dI for the element of volume and then integrating it between R_1 and R_2.



Express the moment of inertia of the element of mass dm:

$$dI = r^2 dm = 2\pi\rho\, h r^3 dr$$

Integrate dI from R_1 to R_2 to obtain:

$$I = 2\pi\rho\, h\int_{R_1}^{R_2} r^3 dr = \tfrac{1}{2}\pi\rho\, h\left(R_2^4 - R_1^4\right)$$
$$= \tfrac{1}{2}\pi\rho\, h\left(R_2^2 - R_1^2\right)\left(R_2^2 + R_1^2\right)$$

The mass of the hollow cylinder is $m = \pi\,\rho\, h\left(R_2^2 - R_1^2\right)$, so:

$$\rho = \frac{m}{\pi\, h\left(R_2^2 - R_1^2\right)}$$

Substitute for ρ and simplify to obtain:

$$I = \tfrac{1}{2}\pi\left(\frac{m}{\pi\, h\left(R_2^2 - R_1^2\right)}\right) h\left(R_2^2 - R_1^2\right)\left(R_2^2 + R_1^2\right) = \boxed{\tfrac{1}{2}m\left(R_2^2 + R_1^2\right)}$$

53 •••

Picture the Problem We can derive the given expression for the moment of inertia of a spherical shell by following the procedure outlined in the problem statement.

Find the moment of inertia of a sphere, with respect to an axis through a diameter, in Table 9-1:

$$I = \tfrac{2}{5}mR^2$$

Express the mass of the sphere as a function of its density and radius:

$$m = \tfrac{4}{3}\pi\,\rho\, R^3$$

Substitute to obtain:

$$I = \tfrac{8}{15}\pi\,\rho\, R^5$$

Express the differential of this expression:

$$dI = \tfrac{8}{3}\pi\,\rho\, R^4 dR \qquad (1)$$

Express the increase in mass dm as the radius of the sphere increases by dR:

$$dm = 4\pi\,\rho\, R^2 dR \qquad (2)$$

Eliminate dR between equations (1) and (2) to obtain:

$$dI = \tfrac{2}{3}R^2 dm$$

Therefore, the moment of inertia of the spherical shell of mass m is $\tfrac{2}{3}mR^2$.

***54** •••

Picture the Problem We can find C in terms of M and R by integrating a spherical shell of mass dm with the given density function to find the mass of the earth as a function of M and then solving for C. In part (b), we'll start with the moment of inertia of the same spherical shell, substitute the earth's density function, and integrate from 0 to R.

(a) Express the mass of the earth using the given density function:

$$M = \int dm = \int_0^R 4\pi\,\rho\, r^2 dr$$

$$= 4\pi\, C\int_0^R 1.22r^2 dr - \frac{4\pi\, C}{R}\int_0^R r^3 dr$$

$$= \frac{4\pi}{3}1.22CR^3 - \pi\, CR^3$$

Solve for C as a function of M and R to obtain:

$$C = \boxed{0.508\frac{M}{R^3}}$$

(b) From Problem 9-40 we have:

$$dI = \tfrac{8}{3}\pi\,\rho\, r^4 dr$$

Integrate to obtain:

$$I = \tfrac{8}{3}\pi\int_0^R \rho\, r^4 dr$$

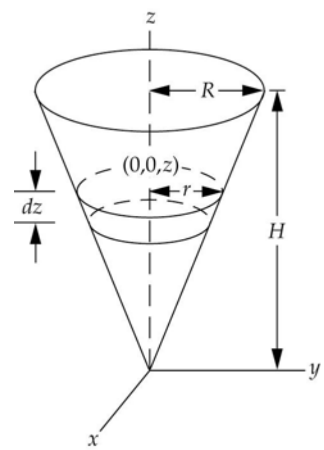
$$= \frac{8\pi(0.508)M}{3R^3}\left[\int_0^R 1.22r^4 dr - \frac{1}{R}\int_0^R r^5 dr\right]$$

$$= \frac{4.26M}{R^3}\left[\frac{1.22}{5}R^5 - \frac{1}{6}R^5\right]$$

$$= \boxed{0.329MR^2}$$

55 •••

Picture the Problem Let the origin be at the apex of the cone, with the z axis along the cone's symmetry axis. Then the radius of the elemental ring, at a distance z from the apex, can be obtained from the proportion $\frac{r}{z}=\frac{R}{H}$. The mass dm of the elemental disk is $\rho dV = \rho\pi r^2 dz$. We'll integrate $r^2 dm$ to find the moment of inertia of the disk in terms of R and H and then integrate dm to obtain a second equation in R and H that we can use to eliminate H in our expression for I.



Express the moment of inertia of the cone in terms of the moment of inertia of the elemental disk:

$$I=\tfrac{1}{2}\int r^2 dm$$
$$=\tfrac{1}{2}\int_0^H \frac{R^2}{H^2}z^2\left(\rho\pi\frac{R^2}{H^2}z^2\right)dz$$
$$=\frac{\pi\rho R^4}{2H^4}\int_0^H z^4 dz=\frac{\pi\rho R^4 H}{10}$$

Express the total mass of the cone in terms of the mass of the elemental disk:

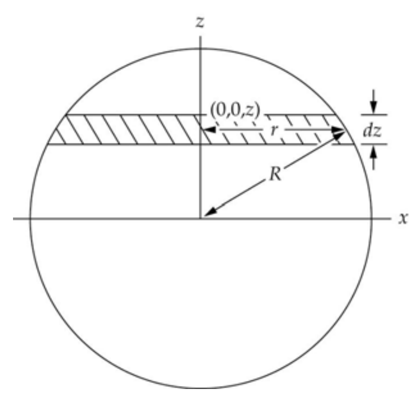
$$M=\pi\rho\int_0^H r^2 dz=\pi\rho\int_0^H \frac{R^2}{H^2}z^2 dz$$
$$=\tfrac{1}{3}\pi\rho R^2 H$$

Divide I by M, simplify, and solve for I to obtain:

$$I=\boxed{\tfrac{3}{10}MR^2}$$

56 •••

Picture the Problem Let the axis of rotation be the x axis. The radius r of the elemental area is $\sqrt{R^2-z^2}$ and its mass, dm, is $\sigma\, dA=2\sigma\sqrt{R^2-z^2}\,dz$. We'll integrate $z^2\, dm$ to determine I in terms of σ and then divide this result by M in order to eliminate σ and express I in terms of M and R.



Express the moment of inertia about the x axis:

$$I = \int z^2 dm = \int z^2 \sigma\, dA = \int_{-R}^{R} z^2 \left(2\sigma\sqrt{R^2 - z^2}\, dz\right) = \tfrac{1}{4}\sigma\pi R^4$$

The mass of the thin uniform disk is:

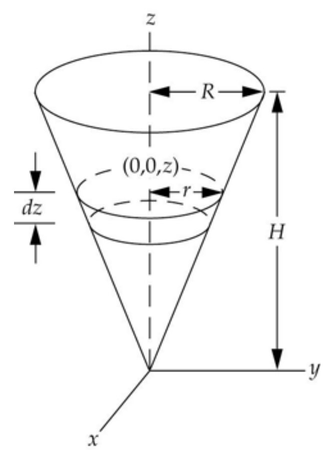
$$M = \sigma\pi R^2$$

Divide I by M, simplify, and solve for I to obtain:

$$I = \boxed{\tfrac{1}{4}MR^2}$$, a result in agreement with the expression given in Table 9-1 for a cylinder of length $L = 0$.

57 •••

Picture the Problem Let the origin be at the apex of the cone, with the z axis along the cone's symmetry axis, and the axis of rotation be the x rotation. Then the radius of the elemental disk, at a distance z from the apex, can be obtained from the proportion $\frac{r}{z} = \frac{R}{H}$. The mass dm of the elemental disk is $\rho dV = \rho\pi r^2 dz$. Each elemental disk rotates about an axis that is parallel to its diameter but removed from it by a distance z. We can use the result from Problem 9-57 for the moment of inertia of the elemental disk with respect to a diameter and then use the parallel axis theorem to express the moment of inertia of the cone with respect to the x axis.



Using the parallel axis theorem, express the moment of inertia of the elemental disk with respect to the x axis:

$$dI_x = dI_{\text{disk}} + dm\, z^2 \qquad (1)$$

where

$$dm = \rho\, dV = \rho\pi\, r^2 dz$$

In Problem 9-57 it was established that the moment of inertia of a thin uniform disk of mass M and radius R rotating about a diameter is $\frac{1}{4}MR^2$. Express this result in

$$dI_{\text{disk}} = \tfrac{1}{4}\left(\rho\pi\, r^2 dz\right)r^2 = \tfrac{1}{4}\rho\pi\left(\frac{R^2}{H^2}z^2\right)^2 dz$$

terms of our elemental disk:

Substitute in equation (1) to obtain:

$$dI_x = \pi\rho\left[\frac{1}{4}\left(\frac{R^2}{H^2}z^2\right)^2\right]dz + \left(\pi\rho\left(\frac{R}{H}z\right)^2 dz\right)z^2$$

Integrate from 0 to H to obtain:

$$I_x = \pi\rho\int_0^H\left[\frac{1}{4}\left(\frac{R^2}{H^2}z^2\right)^2 + \frac{R^2}{H^2}z^4\right]dz = \pi\rho\left(\frac{R^4H}{20} + \frac{R^2H^3}{5}\right)$$

Express the total mass of the cone in terms of the mass of the elemental disk:

$$M = \pi\rho\int_0^H r^2dz = \pi\rho\int_0^H \frac{R^2}{H^2}z^2dz = \tfrac{1}{3}\pi\rho R^2H$$

Divide I_x by M, simplify, and solve for I_x to obtain:

$$I_x = \boxed{3M\left(\frac{H^2}{5} + \frac{R^2}{20}\right)}$$

Remarks: Because both *H* and *R* appear in the numerator, the larger the cones are, the greater their moment of inertia and the greater the energy consumption required to set them into motion.

Rotational Kinetic Energy

58 •

Picture the Problem The kinetic energy of this rotating system of particles can be calculated either by finding the tangential velocities of the particles and using these values to find the kinetic energy or by finding the moment of inertia of the system and using the expression for the rotational kinetic energy of a system.

(a) Use the relationship between v and ω to find the speed of each particle:

$$v_3 = r_3\omega = (0.2\,\text{m})(2\,\text{rad/s}) = 0.4\,\text{m/s}$$

and

$$v_1 = r_1\omega = (0.4\,\text{m})(2\,\text{rad/s}) = 0.8\,\text{m/s}$$

Find the kinetic energy of the system:

$$K = 2K_3 + 2K_1 = m_3v_3^2 + m_1v_1^2$$
$$= (3\,\text{kg})(0.4\,\text{m/s})^2 + (1\,\text{kg})(0.8\,\text{m/s})^2$$
$$= \boxed{1.12\,\text{J}}$$

(*b*) Use the definition of the moment of inertia of a system of particles to obtain:

$$I = \sum_i m_i r_i^2$$
$$= m_1r_1^2 + m_2r_2^2 + m_3r_3^2 + m_4r_4^2$$

Substitute numerical values and evaluate *I*:

$$I = (1\,\text{kg})(0.4\,\text{m})^2 + (3\,\text{kg})(0.2\,\text{m})^2$$
$$+ (1\,\text{kg})(0.4\,\text{m})^2 + (3\,\text{kg})(0.2\,\text{m})^2$$
$$= 0.560\,\text{kg}\cdot\text{m}^2$$

Calculate the kinetic energy of the system of particles:

$$K = \tfrac{1}{2}I\omega^2 = \tfrac{1}{2}(0.560\,\text{kg}\cdot\text{m}^2)(2\,\text{rad/s})^2$$
$$= \boxed{1.12\,\text{J}}$$

***59 •**

Picture the Problem We can find the kinetic energy of this rotating ball from its angular speed and its moment of inertia. We can use the same relationship to find the new angular speed of the ball when it is supplied with additional energy.

(*a*) Express the kinetic energy of the ball:

$$K = \tfrac{1}{2}I\omega^2$$

Express the moment of inertia of ball with respect to its diameter:

$$I = \tfrac{2}{5}MR^2$$

Substitute for *I*:

$$K = \tfrac{1}{5}MR^2\omega^2$$

Substitute numerical values and evaluate *K*:

$$K = \tfrac{1}{5}(1.4\,\text{kg})(0.075\,\text{m})^2$$
$$\times\left(70\frac{\text{rev}}{\text{min}}\times\frac{2\pi\,\text{rad}}{\text{rev}}\times\frac{1\,\text{min}}{60\,\text{s}}\right)^2$$
$$= \boxed{84.6\,\text{mJ}}$$

(*b*) Express the new kinetic energy with K' = 2.0846 J:

$$K' = \tfrac{1}{2}I\omega'^2$$

Express the ratio of *K* to *K'*:

$$\frac{K'}{K} = \frac{\frac{1}{2}I\omega'^2}{\frac{1}{2}I\omega'^2} = \left(\frac{\omega'}{\omega}\right)^2$$

Solve for ω':

$$\omega' = \omega\sqrt{\frac{K'}{K}}$$

Substitute numerical values and evaluate ω':

$$\omega' = (70\,\text{rev/min})\sqrt{\frac{2.0846\,\text{J}}{0.0846\,\text{J}}} = \boxed{347\,\text{rev/min}}$$

60 •

Picture the Problem The power delivered by an engine is the product of the torque it develops and the angular speed at which it delivers the torque.

Express the power delivered by the engine as a function of the torque it develops and the angular speed at which it delivers this torque:

$$P = \tau\omega$$

Substitute numerical values and evaluate P:

$$P = (400\,\text{N}\cdot\text{m})\left(3700\frac{\text{rev}}{\text{min}}\times\frac{2\pi\,\text{rad}}{\text{rev}}\times\frac{1\,\text{min}}{60\,\text{s}}\right) = \boxed{155\,\text{kW}}$$

61 ••

Picture the Problem Let r_1 and r_2 be the distances of m_1 and m_2 from the center of mass. We can use the definition of rotational kinetic energy and the definition of the center of mass of the two point masses to show that $K_1/K_2 = m_2/m_1$.

Use the definition of rotational kinetic energy to express the ratio of the rotational kinetic energies:

$$\frac{K_1}{K_2} = \frac{\frac{1}{2}I\omega_1^2}{\frac{1}{2}I\omega_2^2} = \frac{m_1r_1^2\omega^2}{m_2r_2^2\omega^2} = \frac{m_1r_1^2}{m_2r_2^2}$$

Use the definition of the center of mass to relate m_1, m_2, r_1, and r_2:

$$r_1m_1 = r_2m_2$$

Solve for $\frac{r_1}{r_2}$, substitute and simplify to obtain:

$$\frac{K_1}{K_2} = \frac{m_1}{m_2}\left(\frac{m_2}{m_1}\right)^2 = \boxed{\frac{m_2}{m_1}}$$

62 ••

Picture the Problem The earth's rotational kinetic energy is given by $K_{\text{rot}} = \frac{1}{2}I\omega^2$ where I is its moment of inertia with respect to its axis of rotation. The center of mass of the earth-sun system is so close to the center of the sun and the earth-sun distance so large that we can use the earth-sun distance as the separation of their centers of mass and assume each to be point mass.

Express the rotational kinetic energy of the earth:

$$K_{rot} = \tfrac{1}{2} I\omega^2 \qquad (1)$$

Find the angular speed of the earth's rotation using the definition of ω:

$$\omega = \frac{\Delta\theta}{\Delta t} = \frac{2\pi\,\text{rad}}{24\,\text{h}\times\dfrac{3600\,\text{s}}{\text{h}}} = 7.27\times10^{-5}\,\text{rad/s}$$

From Table 9-1, for the moment of inertia of a homogeneous sphere, we find:

$$I = \tfrac{2}{5} MR^2 = \tfrac{2}{5}\left(6.0\times10^{24}\,\text{kg}\right)\left(6.4\times10^{6}\,\text{m}\right)^2 = 9.83\times10^{37}\,\text{kg}\cdot\text{m}^2$$

Substitute numerical values in equation (1) to obtain:

$$K_{rot} = \tfrac{1}{2}\left(9.83\times10^{37}\,\text{kg}\cdot\text{m}^2\right)\times\left(7.27\times10^{-5}\,\text{rad/s}\right)^2 = \boxed{2.60\times10^{29}\,\text{J}}$$

Express the earth's orbital kinetic energy:

$$K_{orb} = \tfrac{1}{2} I\omega_{orb}^2 \qquad (2)$$

Find the angular speed of the center of mass of the earth-sun system:

$$\omega = \frac{\Delta\theta}{\Delta t} = \frac{2\pi\,\text{rad}}{365.25\,\text{days}\times 24\dfrac{\text{h}}{\text{day}}\times\dfrac{3600\,\text{s}}{\text{h}}} = 1.99\times10^{-7}\,\text{rad/s}$$

Express and evaluate the orbital moment of inertia of the earth:

$$I = M_E R_{orb}^2 = \left(6.0\times10^{24}\,\text{kg}\right)\left(1.50\times10^{11}\,\text{m}\right)^2 = 1.35\times10^{47}\,\text{kg}\cdot\text{m}^2$$

Substitute in equation (2) to obtain:

$$K_{orb} = \tfrac{1}{2}\left(1.35\times10^{47}\,\text{kg}\cdot\text{m}^2\right)\times\left(1.99\times10^{-7}\,\text{rad/s}\right)^2 = 2.67\times10^{33}\,\text{J}$$

Evaluate the ratio $\frac{K_{\text{orb}}}{K_{\text{rot}}}$:

$$\frac{K_{\text{orb}}}{K_{\text{rot}}} = \frac{2.67\times10^{33}\ \text{J}}{2.60\times10^{29}\ \text{J}} \approx \boxed{10^4}$$

***63 ••**

Picture the Problem Because the load is not being accelerated, the tension in the cable equals the weight of the load. The role of the massless pulley is to change the direction the force (tension) in the cable acts.

(*a*) Because the block is lifted at constant speed:

$$T = mg = (2000\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{19.6\,\text{kN}}$$

(*b*) Apply the definition of torque at the winch drum:

$$\tau = Tr = (19.6\,\text{kN})(0.30\,\text{m}) = \boxed{5.89\,\text{kN}\cdot\text{m}}$$

(*c*) Relate the angular speed of the winch drum to the rate at which the load is being lifted (the tangential speed of the cable on the drum):

$$\omega = \frac{v}{r} = \frac{0.08\,\text{m/s}}{0.30\,\text{m}} = \boxed{0.267\,\text{rad/s}}$$

(*d*) Express the power developed by the motor in terms of the tension in the cable and the speed with which the load is being lifted:

$$P = Tv = (19.6\,\text{kN})(0.08\,\text{m/s}) = \boxed{1.57\,\text{kW}}$$

64 ••

Picture the Problem Let the zero of gravitational potential energy be at the lowest point of the small particle. We can use conservation of energy to find the angular velocity of the disk when the particle is at its lowest point and Newton's 2nd law to find the force the disk will have to exert on the particle to keep it from falling off.

(*a*) Use conservation of energy to relate the initial potential energy of the system to its rotational kinetic energy when the small particle is at its lowest point:

$$\Delta K + \Delta U = 0$$

or, because $U_f = K_i = 0$,

$$\tfrac{1}{2}\left(I_{\text{disk}} + I_{\text{particle}}\right)\omega_f^2 - mg\Delta h = 0$$

Solve for ω_f:

$$\omega_f = \sqrt{\frac{2mg\Delta h}{I_{\text{disk}} + I_{\text{particle}}}}$$

Substitute for I_{disk}, $I_{particle}$, and Δh and simplify to obtain:

$$\omega_f = \sqrt{\frac{2mg(2R)}{\frac{1}{2}MR^2 + mR^2}} = \boxed{\sqrt{\frac{8mg}{R(2m+M)}}}$$

(*b*) The mass is in uniform circular motion at the bottom of the disk, so the sum of the force *F* exerted by the disk and the gravitational force must be the centripetal force:

$$F - mg = mR\omega_f^2$$

Solve for *F* and simplify to obtain:

$$F = mg + mR\omega_f^2$$
$$= mg + mR\left(\frac{8mg}{R(2mM)}\right)$$
$$= \boxed{mg\left(1 + \frac{8m}{2m+M}\right)}$$

65 ••

Picture the Problem Let the zero of gravitational potential energy be at the center of mass of the ring when it is directly below the point of support. We'll use conservation of energy to relate the maximum angular velocity and the initial angular velocity required for a complete revolution to the changes in the potential energy of the ring.

(*a*) Use conservation of energy to relate the initial potential energy of the ring to its rotational kinetic energy when its center of mass is directly below the point of support:

$$\Delta K + \Delta U = 0$$

or, because $U_f = K_i = 0$,

$$\tfrac{1}{2}I_P\omega_{max}^2 - mg\Delta h = 0 \qquad (1)$$

Use the parallel axis theorem and Table 9-1 to express the moment of inertia of the ring with respect to its pivot point *P*:

$$I_P = I_{cm} + mR^2$$

Substitute in equation (1) to obtain:

$$\tfrac{1}{2}\left(mR^2 + mR^2\right)\omega_{max}^2 - mgR = 0$$

Solve for ω_{max}:

$$\omega_{max} = \sqrt{\frac{g}{R}}$$

Substitute numerical values and evaluate ω_{max}:

$$\omega_{max} = \sqrt{\frac{9.81\,\text{m/s}^2}{0.75\,\text{m}}} = \boxed{3.62\,\text{rad/s}}$$

(*b*) Use conservation of energy to relate the final potential energy of the ring to its initial rotational kinetic energy:

$$\Delta K + \Delta U = 0$$

or, because $U_\text{i} = K_\text{f} = 0$,

$$-\tfrac{1}{2} I_P \omega_\text{i}^2 + mg\Delta h = 0$$

Noting that the center of mass must rise a distance R if the ring is to make a complete revolution, substitute for I_P and Δh to obtain:

$$-\tfrac{1}{2}\left(mR^2 + mR^2\right)\omega_\text{i}^2 + mgR = 0$$

Solve for ω_i:

$$\omega_i = \sqrt{\frac{g}{R}}$$

Substitute numerical values and evaluate ω_i:

$$\omega_i = \sqrt{\frac{9.81\,\text{m/s}^2}{0.75\,\text{m}}} = \boxed{3.62\,\text{rad/s}}$$

66 ••

Picture the Problem We can find the energy that must be stored in the flywheel and relate this energy to the radius of the wheel and use the definition of rotational kinetic energy to find the wheel's radius.

Relate the kinetic energy of the flywheel to the energy it must deliver:

$$K_\text{rot} = \tfrac{1}{2} I_\text{cyl}\omega^2 = (2\,\text{MJ/km})(300\,\text{km}) = 600\,\text{MJ}$$

Express the moment of inertia of the flywheel:

$$I_\text{cyl} = \tfrac{1}{2} MR^2$$

Substitute for I_cyl and solve for ω:

$$R = \frac{2}{\omega}\sqrt{\frac{K_\text{rot}}{M}}$$

Substitute numerical values and evaluate R:

$$R = \frac{2}{400\,\dfrac{\text{rev}}{\text{s}} \times \dfrac{2\pi\,\text{rad}}{\text{rev}}}\sqrt{\frac{600\,\text{MJ} \times \dfrac{10^6\,\text{J}}{\text{MJ}}}{100\,\text{kg}}} = \boxed{1.95\,\text{m}}$$

67 ••

Picture the Problem We'll solve this problem for the general case of a ladder of length L, mass M, and person of mass m. Let the zero of gravitational potential energy be at floor level and include you, the ladder, and the earth in the system. We'll use conservation of energy to relate your impact speed falling freely to your impact speed riding the ladder to the ground.

Use conservation of energy to relate the speed with which a person will strike the ground to the fall distance L:

$$\Delta K + \Delta U = 0$$

or, because $K_\text{i} = U_\text{f} = 0$,

$$\tfrac{1}{2} m v_\text{f}^2 - mgL = 0$$

Solve for v_f^2:

$$v_\text{f}^2 = 2gL$$

Letting ω_r represent the angular velocity of the ladder+person system as it strikes the ground, use conservation of energy to relate the initial and final momenta of the system:

$$\Delta K + \Delta U = 0$$

or, because $K_\text{i} = U_\text{f} = 0$,

$$\tfrac{1}{2}\left(I_\text{person} + I_\text{ladder}\right)\omega_\text{r}^2 - \left(mgL + Mg\frac{L}{2}\right) = 0$$

Substitute for the moments of inertia to obtain:

$$\tfrac{1}{2}\left(m + \frac{1}{3}M\right)L^2\omega_\text{f}^2 - \left(mgL + Mg\frac{L}{2}\right) = 0$$

Substitute v_r for $L\omega_\text{f}$ and solve for v_r^2:

$$v_\text{r}^2 = \frac{2gL\left(m + \frac{M}{2}\right)}{m + \frac{M}{3}}$$

Express the ratio $\dfrac{v_\text{r}^2}{v_\text{f}^2}$:

$$\frac{v_\text{r}^2}{v_\text{f}^2} = \frac{m + \frac{M}{2}}{m + \frac{M}{3}}$$

Solve for v_r to obtain:

$$v_\text{r} = v_\text{f}\sqrt{\frac{6m + 3M}{6m + 2M}}$$

Unless M, the mass of the ladder, is zero, $v_\text{r} > v_\text{f}$. It is better to let go and fall to the ground.

Pulleys, Yo-Yos, and Hanging Things

***68 ••**

Picture the Problem We'll solve this problem for the general case in which the mass of the block on the ledge is M, the mass of the hanging block is m, and the mass of the pulley is M_p, and R is the radius of the pulley. Let the zero of gravitational potential energy be 2.5 m below the initial position of the 2-kg block and R represent the radius of the pulley. Let the system include both blocks, the shelf and pulley, and the earth. The initial potential energy of the 2-kg block will be transformed into the translational kinetic energy of both blocks plus rotational kinetic energy of the pulley.

(*a*) Use energy conservation to relate the speed of the 2 kg block when it has fallen a distance Δh to its initial potential energy and the kinetic energy of the system:

$$\Delta K + \Delta U = 0$$

or, because $K_i = U_f = 0$,

$$\tfrac{1}{2}(m+M)v^2 + \tfrac{1}{2}I_{\text{pulley}}\omega^2 - mgh = 0$$

Substitute for I_{pulley} and ω to obtain:

$$\tfrac{1}{2}(m+M)v^2 + \tfrac{1}{2}\left(\tfrac{1}{2}MR^2\right)\frac{v^2}{R^2} - mgh = 0$$

Solve for v:

$$v = \sqrt{\frac{2mgh}{M + m + \frac{1}{2}M_p}}$$

Substitute numerical values and evaluate v:

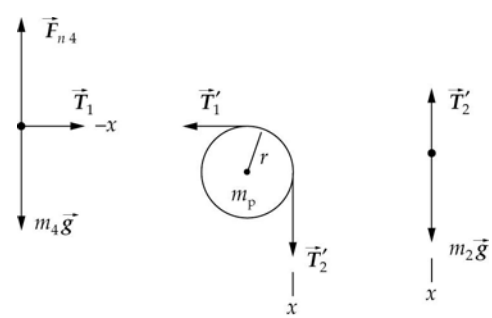
$$v = \sqrt{\frac{2(2\,\text{kg})(9.81\,\text{m/s}^2)(2.5\,\text{m})}{4\text{kg} + 2\,\text{kg} + \frac{1}{2}(0.6\,\text{kg})}} = \boxed{3.95\,\text{m/s}}$$

(*b*) Find the angular velocity of the pulley from its tangential speed:

$$\omega = \frac{v}{R} = \frac{3.95\,\text{m/s}}{0.08\,\text{m}} = \boxed{49.3\,\text{rad/s}}$$

69 ••

Picture the Problem The diagrams show the forces acting on each of the masses and the pulley. We can apply Newton's 2nd law to the two blocks and the pulley to obtain three equations in the unknowns T_1, T_2, and a.



Apply Newton's 2nd law to the two blocks and the pulley:

$$\sum F_x = T_1 = m_4 a\,, \qquad (1)$$

$$\sum \tau_p = (T_2 - T_1)r = I_p\alpha\,, \qquad (2)$$

and

$$\sum F_x = m_2 g - T_2 = m_2 a \qquad (3)$$

Eliminate α in equation (2) to obtain:

$$T_2 - T_1 = \tfrac{1}{2}M_p a \qquad (4)$$

Eliminate T_1 and T_2 between equations (1), (3) and (4) and solve for a:

$$a = \frac{m_2 g}{m_2 + m_4 + \frac{1}{2}M_p}$$

Substitute numerical values and evaluate a:

$$a = \frac{(2\,\text{kg})(9.81\,\text{m/s}^2)}{2\,\text{kg} + 4\,\text{kg} + \frac{1}{2}(0.6\,\text{kg})} = \boxed{3.11\,\text{m/s}^2}$$

Using equation (1), evaluate T_1:

$$T_1 = (4\,\text{kg})(3.11\,\text{m/s}^2) = \boxed{12.5\,\text{N}}$$

Solve equation (3) for T_2:

$$T_2 = m_2(g - a)$$

Substitute numerical values and evaluate T_2:

$$T_2 = (2\,\text{kg})(9.81\,\text{m/s}^2 - 3.11\,\text{m/s}^2) = \boxed{13.4\,\text{N}}$$

70 ••

Picture the Problem We'll solve this problem for the general case in which the mass of the block on the ledge is M, the mass of the hanging block is m, the mass of the pulley is M_p, and R is the radius of the pulley. Let the zero of gravitational potential energy be 2.5 m below the initial position of the 2-kg block. The initial potential energy of the 2-kg block will be transformed into the translational kinetic energy of both blocks plus rotational kinetic energy of the pulley plus work done against friction.

(*a*) Use energy conservation to relate the speed of the 2 kg block when it has fallen a distance Δh to its initial potential energy, the kinetic energy of the system and the work done against friction:

$$\Delta K + \Delta U + W_f = 0$$

or, because $K_i = U_f = 0$,

$$\tfrac{1}{2}(m+M)v^2 + \tfrac{1}{2}I_{\text{pulley}}\omega^2 - mgh + \mu_k Mgh = 0$$

Substitute for I_{pulley} and ω to obtain:

$$\tfrac{1}{2}(m+M)v^2 + \tfrac{1}{2}\left(\tfrac{1}{2}M_p\right)\frac{v^2}{R^2} - mgh + \mu_k Mgh = 0$$

Solve for v:

$$v = \sqrt{\frac{2gh(m - \mu_k M)}{M + m + \frac{1}{2}M_p}}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{\frac{2(9.81\,\text{m/s}^2)(2.5\,\text{m})[2\,\text{kg} - (0.25)(4\,\text{kg})]}{4\text{kg} + 2\,\text{kg} + \frac{1}{2}(0.6\,\text{kg})}} = \boxed{2.79\,\text{m/s}}$$

(b) Find the angular velocity of the pulley from its tangential speed:

$$\omega = \frac{v}{R} = \frac{2.79\,\text{m/s}}{0.08\,\text{m}} = \boxed{34.9\,\text{rad/s}}$$

71 ••

Picture the Problem Let the zero of gravitational potential energy be at the water's surface and let the system include the winch, the car, and the earth. We'll apply energy conservation to relate the car's speed as it hits the water to its initial potential energy. Note that some of the car's initial potential energy will be transformed into rotational kinetic energy of the winch and pulley.

Use energy conservation to relate the car's speed as it hits the water to its initial potential energy:

$$\Delta K + \Delta U = 0$$

or, because $K_i = U_f = 0$,

$$\tfrac{1}{2}mv^2 + \tfrac{1}{2}I_w\omega_w^2 + \tfrac{1}{2}I_p\omega_p^2 - mg\Delta h = 0$$

Express ω_w and ω_p in terms of the speed v of the rope, which is the same throughout the system:

$$\omega_w = \frac{v^2}{r_w^2} \text{ and } \omega_p = \frac{v^2}{r_p^2}$$

Substitute to obtain:

$$\tfrac{1}{2}mv^2 + \tfrac{1}{2}I_w\frac{v^2}{r_w^2} + \tfrac{1}{2}I_p\frac{v^2}{r_p^2} - mg\Delta h = 0$$

Solve for v:

$$v = \sqrt{\frac{2mg\Delta h}{m + \frac{I_w}{r_w^2} + \frac{I_p}{r_p^2}}}$$

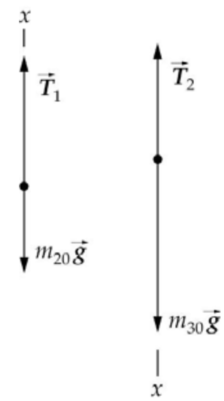
Substitute numerical values and evaluate v:

$$v = \sqrt{\frac{2(1200\,\text{kg})(9.81\,\text{m/s}^2)(5\,\text{m})}{1200\,\text{kg} + \frac{320\,\text{kg}\cdot\text{m}^2}{(0.8\,\text{m})^2} + \frac{4\,\text{kg}\cdot\text{m}^2}{(0.3\,\text{m})^2}}}$$

$$= \boxed{8.21\,\text{m/s}}$$

***72 ••**

Picture the Problem Let the system include the blocks, the pulley and the earth. Choose the zero of gravitational potential energy to be at the ledge and apply energy conservation to relate the impact speed of the 30-kg block to the initial potential energy of the system. We can use a constant-acceleration equations and Newton's 2nd law to find the tensions in the strings and the descent time.



(*a*) Use conservation of energy to relate the impact speed of the 30-kg block to the initial potential energy of the system:

$$\Delta K + \Delta U = 0$$

or, because $K_i = U_f = 0$,

$$\tfrac{1}{2}m_{30}v^2 + \tfrac{1}{2}m_{20}v^2 + \tfrac{1}{2}I_p\omega_p^2 + m_{20}g\Delta h - m_{30}g\Delta h = 0$$

Substitute for ω_p and I_p to obtain:

$$\tfrac{1}{2}m_{30}v^2 + \tfrac{1}{2}m_{20}v^2 + \tfrac{1}{2}\left(\tfrac{1}{2}M_p r^2\right)\left(\frac{v^2}{r^2}\right) + m_{20}g\Delta h - m_{30}g\Delta h = 0$$

Solve for v:

$$v = \sqrt{\frac{2g\Delta h(m_{30} - m_{20})}{m_{20} + m_{30} + \tfrac{1}{2}M_p}}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{\frac{2(9.81\,\text{m/s}^2)(2\,\text{m})(30\,\text{kg} - 20\,\text{kg})}{20\,\text{kg} + 30\,\text{kg} + \tfrac{1}{2}(5\,\text{kg})}} = \boxed{2.73\,\text{m/s}}$$

(*b*) Find the angular speed at impact from the tangential speed at impact and the radius of the pulley:

$$\omega = \frac{v}{r} = \frac{2.73\,\text{m/s}}{0.1\,\text{m}} = \boxed{27.3\,\text{rad/s}}$$

(*c*) Apply Newton's 2nd law to the blocks:

$$\sum F_x = T_1 - m_{20}g = m_{20}a \qquad (1)$$

$$\sum F_x = m_{30}g - T_2 = m_{30}a \qquad (2)$$

Using a constant-acceleration equation, relate the speed at impact to the fall distance and the

$$v^2 = v_0^2 + 2a\Delta h$$

or, because $v_0 = 0$,

acceleration and solve for and evaluate a:

$$a = \frac{v^2}{2\Delta h} = \frac{(2.73\,\text{m/s})^2}{2(2\,\text{m})} = 1.87\,\text{m/s}^2$$

Substitute in equation (1) to find T_1:

$$T_1 = m_{20}(g + a) = (20\,\text{kg})(9.81\,\text{m/s}^2 + 1.87\,\text{m/s}^2) = \boxed{234\,\text{N}}$$

Substitute in equation (2) to find T_2:

$$T_2 = m_{30}(g - a) = (30\,\text{kg})(9.81\,\text{m/s}^2 - 1.87\,\text{m/s}^2) = \boxed{238\,\text{N}}$$

(*d*) Noting that the initial speed of the 30-kg block is zero, express the time-of-fall in terms of the fall distance and the block's average speed:

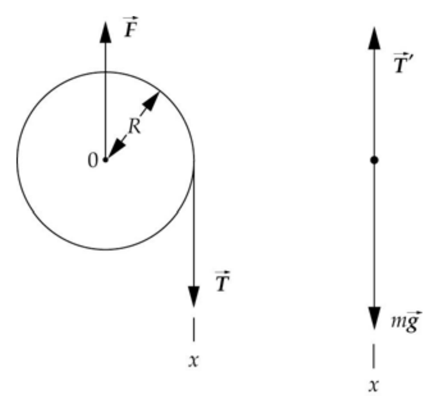
$$\Delta t = \frac{\Delta h}{v_{\text{av}}} = \frac{\Delta h}{\frac{1}{2}v} = \frac{2\Delta h}{v}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{2(2\,\text{m})}{2.73\,\text{m/s}} = \boxed{1.47\,\text{s}}$$

73 ••

Picture the Problem The force diagram shows the forces acting on the sphere and the hanging object. The tension in the string is responsible for the angular acceleration of the sphere and the difference between the weight of the object and the tension is the net force acting on the hanging object. We can use Newton's 2nd law to obtain two equations in a and T that we can solve simultaneously.



(*a*)Apply Newton's 2nd law to the sphere and the hanging object:

$$\sum \tau_0 = TR = I_{\text{sphere}}\alpha \qquad (1)$$

and

$$\sum F_x = mg - T = ma \qquad (2)$$

Substitute for I_{sphere} and α in equation (1) to obtain:

$$TR = \left(\tfrac{2}{5}MR^2\right)\frac{a}{R} \qquad (3)$$

Eliminate T between equations (2) and (3) and solve for a to obtain:

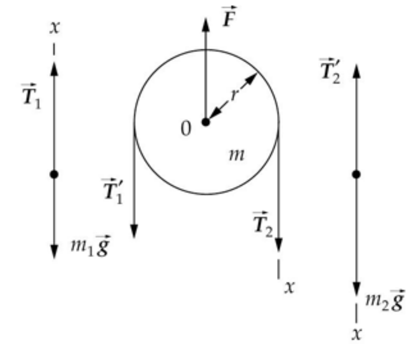
$$a = \boxed{\frac{g}{1+\frac{2M}{5m}}}$$

(*b*) Substitute for a in equation (2) and solve for T to obtain:

$$T = \boxed{\frac{2mMg}{5m+2M}}$$

74 ••

Picture the Problem The diagram shows the forces acting on both objects and the pulley. By applying Newton's 2nd law of motion, we can obtain a system of three equations in the unknowns T_1, T_2, and a that we can solve simultaneously.



(*a*) Apply Newton's 2nd law to the pulley and the two objects:

$$\sum F_x = T_1 - m_1 g = m_1 a\,, \qquad (1)$$

$$\sum \tau_0 = (T_2 - T_1)r = I_0\alpha\,, \qquad (2)$$

and

$$\sum F_x = m_2 g - T_2 = m_2 a \qquad (3)$$

Substitute for $I_0 = I_{\text{pulley}}$ and α in equation (2) to obtain:

$$(T_2 - T_1)r = \left(\tfrac{1}{2}mr^2\right)\frac{a}{r} \qquad (4)$$

Eliminate T_1 and T_2 between equations (1), (3) and (4) and solve for a to obtain:

$$a = \frac{(m_2 - m_1)g}{m_1 + m_2 + \frac{1}{2}m}$$

Substitute numerical values and evaluate a:

$$a = \frac{(510\,\text{g} - 500\,\text{g})(981\,\text{cm/s}^2)}{500\,\text{g} + 510\,\text{g} + \frac{1}{2}(50\,\text{g})} = \boxed{9.478\,\text{cm/s}^2}$$

(*b*) Substitute for a in equation (1) and solve for T_1 to obtain:

$$T_1 = m_1(g + a) = (0.500\,\text{kg})(9.81\,\text{m/s}^2 + 0.09478\,\text{m/s}^2) = \boxed{4.9524\,\text{N}}$$

Substitute for a in equation (3) and solve for T_2 to obtain:

$$T_2 = m_2(g-a)$$
$$= (0.510\,\text{kg})(9.81\,\text{m/s}^2 - 0.09478\,\text{m/s}^2)$$
$$= \boxed{4.9548\,\text{N}}$$

Find ΔT:

$$\Delta T = T_2 - T_1 = 4.9548\,\text{N} - 4.9524\,\text{N}$$
$$= \boxed{0.0024\,\text{N}}$$

(c) If we ignore the mass of the pulley, our acceleration equation is:

$$a = \frac{(m_2 - m_1)g}{m_1 + m_2}$$

Substitute numerical values and evaluate a:

$$a = \frac{(510\,\text{g} - 500\,\text{g})(981\,\text{cm/s}^2)}{500\,\text{g} + 510\,\text{g}}$$
$$= \boxed{9.713\,\text{cm/s}^2}$$

Substitute for a in equation (1) and solve for T_1 to obtain:

$$T_1 = m_1(g+a)$$

Substitute numerical values and evaluate T_1:

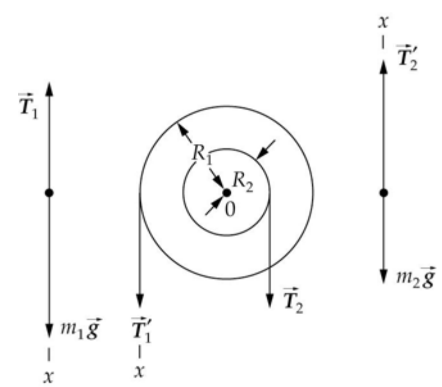
$$T_1 = (0.500\,\text{kg})(9.81\,\text{m/s}^2 + 0.09713\,\text{m/s}^2) = \boxed{4.9536\,\text{N}}$$

From equation (4), if m = 0:

$$\boxed{T_1 = T_2}$$

***75 ••**

Picture the Problem The diagram shows the forces acting on both objects and the pulley. By applying Newton's 2nd law of motion, we can obtain a system of three equations in the unknowns T_1, T_2, and α that we can solve simultaneously.



(a) Express the condition that the system does not accelerate:

$$\tau_{\text{net}} = m_1 g R_1 - m_2 g R_2 = 0$$

Solve for m_2:

$$m_2 = m_1 \frac{R_1}{R_2}$$

Substitute numerical values and evaluate m_2:

$$m_2 = (24\,\text{kg})\frac{1.2\,\text{m}}{0.4\,\text{m}} = \boxed{72.0\,\text{kg}}$$

(*b*) Apply Newton's 2nd law to the objects and the pulley:

$$\sum F_x = m_1 g - T_1 = m_1 a\,, \qquad (1)$$

$$\sum \tau_0 = T_1 R_1 - T_2 R_2 = I_0 \alpha\,, \qquad (2)$$

and

$$\sum F_x = T_2 - m_2 g = m_2 a \qquad (3)$$

Eliminate a in favor of α in equations (1) and (3) and solve for T_1 and T_2:

$$T_1 = m_1(g - R_1\alpha) \qquad (4)$$

and

$$T_2 = m_2(g + R_2\alpha) \qquad (5)$$

Substitute for T_1 and T_2 in equation (2) and solve for α to obtain:

$$\alpha = \frac{(m_1 R_1 - m_2 R_2)g}{m_1 R_1^2 + m_2 R_2^2 + I_0}$$

Substitute numerical values and evaluate α:

$$\alpha = \frac{[(36\,\text{kg})(1.2\,\text{m}) - (72\,\text{kg})(0.4\,\text{m})](9.81\,\text{m/s}^2)}{(36\,\text{kg})(1.2\,\text{m})^2 + (72\,\text{kg})(0.4\,\text{m})^2 + 40\,\text{kg}\cdot\text{m}^2} = \boxed{1.37\,\text{rad/s}^2}$$

Substitute in equation (4) to find T_1:

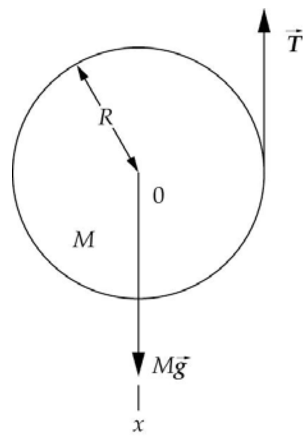
$$T_1 = (36\,\text{kg})\left[9.81\,\text{m/s}^2 - (1.2\,\text{m})(1.37\,\text{rad/s}^2)\right] = \boxed{294\,\text{N}}$$

Substitute in equation (5) to find T_2:

$$T_2 = (72\,\text{kg})\left[9.81\,\text{m/s}^2 + (0.4\,\text{m})(1.37\,\text{rad/s}^2)\right] = \boxed{746\,\text{N}}$$

76 ••

Picture the Problem Choose the coordinate system shown in the diagram. By applying Newton's 2nd law of motion, we can obtain a system of two equations in the unknowns T and a. In (b) we can use the torque equation from (a) and our value for T to find α. In (c) we use the condition that the acceleration of a point on the rim of the cylinder is the same as the acceleration of the hand, together with the angular acceleration of the cylinder, to find the acceleration of the hand.



(a) Apply Newton's 2nd law to the cylinder about an axis through its center of mass:

$$\sum \tau_0 = TR = I_0 \frac{a}{R} \quad (1)$$

and

$$\sum F_x = Mg - T = 0 \quad (2)$$

Solve for T to obtain:

$$T = \boxed{Mg}$$

(b) Rewrite equation (1) in terms of α:

$$TR = I_0 \alpha$$

Solve for α:

$$\alpha = \frac{TR}{I_0}$$

Substitute for T and I_0 to obtain:

$$\alpha = \frac{MgR}{\frac{1}{2}MR^2} = \boxed{\frac{2g}{R}}$$

(c) Relate the acceleration a of the hand to the angular acceleration of the cylinder:

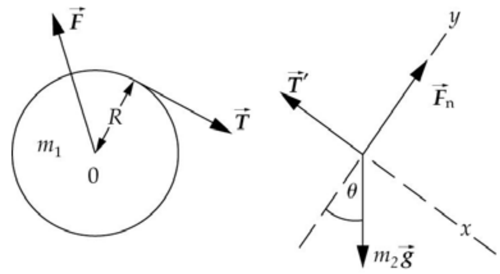
$$a = R\alpha$$

Substitute for α to obtain:

$$a = R\left(\frac{2g}{R}\right) = \boxed{2g}$$

77 ••

Picture the Problem Let the zero of gravitational potential energy be at the bottom of the incline. By applying Newton's 2nd law to the cylinder and the block we can obtain simultaneous equations in a, T, and α from which we can express a and T. By applying the conservation of energy, we can derive an expression for the speed of the block when it reaches the bottom of the incline.



(*a*) Apply Newton's 2nd law to the cylinder and the block:

$$\sum \tau_0 = TR = I_0\alpha \qquad (1)$$

and

$$\sum F_x = m_2 g\sin\theta - T = m_2 a \qquad (2)$$

Substitute for α in equation (1), solve for T, and substitute in equation (2) and solve for a to obtain:

$$a = \boxed{\frac{g\sin\theta}{1+\dfrac{m_1}{2m_2}}}$$

(*b*) Substitute for a in equation (2) and solve for T:

$$T = \boxed{\frac{\frac{1}{2}m_1 g\sin\theta}{1+\dfrac{m_1}{2m_2}}}$$

(*c*) Noting that the block is released from rest, express the total energy of the system when the block is at height h:

$$E = U + K = \boxed{m_2 gh}$$

(*d*) Use the fact that this system is conservative to express the total energy at the bottom of the incline:

$$E_{\text{bottom}} = \boxed{m_2 gh}$$

(*e*) Express the total energy of the system when the block is at the bottom of the incline in terms of its kinetic energies:

$$E_{\text{bottom}} = K_{\text{tran}} + K_{\text{rot}} = \tfrac{1}{2}m_2v^2 + \tfrac{1}{2}I_0\omega^2$$

Substitute for ω and I_0 to obtain:

$$\tfrac{1}{2}m_2v^2 + \tfrac{1}{2}\left(\tfrac{1}{2}m_1r^2\right)\frac{v^2}{r^2} = m_2gh$$

Solve for v to obtain:

$$v = \boxed{\sqrt{\frac{2gh}{1+\frac{m_1}{2m_2}}}}$$

(f) For $\theta = 0$:

$$\boxed{a = T = 0}$$

For $\theta = 90°$:

$$a = \boxed{\frac{g}{1+\frac{m_1}{2m_2}}},$$

$$T = \frac{\frac{1}{2}m_1g}{1+\frac{m_1}{2m_2}} = \boxed{\tfrac{1}{2}m_1a},$$

and

$$v = \boxed{\sqrt{\frac{2gh}{1+\frac{m_1}{2m_2}}}}$$

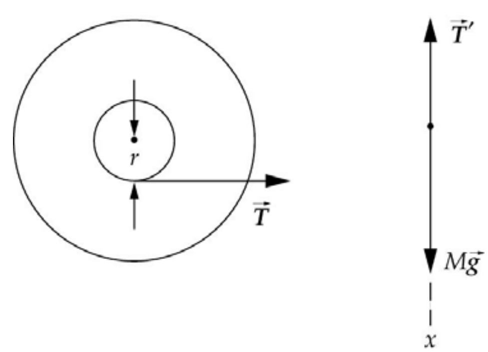
For $m_1 = 0$:

$a = \boxed{g\sin\theta}$, $T = \boxed{0}$, and

$v = \boxed{\sqrt{2gh}}$

***78 ••**

Picture the Problem Let r be the radius of the concentric drum (10 cm) and let I_0 be the moment of inertia of the drum plus platform. We can use Newton's 2nd law in both translational and rotational forms to express I_0 in terms of a and a constant-acceleration equation to express a and then find I_0. We can use the same equation to find the total moment of inertia when the object is placed on the platform and then subtract to find its moment of inertia.



(a) Apply Newton's 2nd law to the platform and the weight:

$$\sum \tau_0 = Tr = I_0\alpha \qquad (1)$$

$$\sum F_x = Mg - T = Ma \qquad (2)$$

Substitute a/r for α in equation (1) and solve for T:

$$T = \frac{I_0}{r^2} a$$

Substitute for T in equation (2) and solve for a to obtain:

$$I_0 = \frac{Mr^2(g - a)}{a} \qquad (3)$$

Using a constant-acceleration equation, relate the distance of fall to the acceleration of the weight and the time of fall and solve for the acceleration:

$$\Delta x = v_0 \Delta t + \tfrac{1}{2} a (\Delta t)^2$$

or, because $v_0 = 0$ and $\Delta x = D$,

$$a = \frac{2D}{(\Delta t)^2}$$

Substitute for a in equation (3) to obtain:

$$I_0 = Mr^2\left(\frac{g}{a} - 1\right) = Mr^2\left(\frac{g(\Delta t)^2}{2D} - 1\right)$$

Substitute numerical values and evaluate I_0:

$$I_0 = (2.5\,\text{kg})(0.1\,\text{m})^2 \times \left[\frac{(9.81\,\text{m/s}^2)(4.2\,\text{s})^2}{2(1.8\,\text{m})} - 1\right] = \boxed{1.177\,\text{kg}\cdot\text{m}^2}$$

(b) Relate the moments of inertia of the platform, drum, shaft, and pulley (I_0) to the moment of inertia of the object and the total moment of inertia:

$$I_{\text{tot}} = I_0 + I = Mr^2\left(\frac{g}{a} - 1\right) = Mr^2\left(\frac{g(\Delta t)^2}{2D} - 1\right)$$

Substitute numerical values and evaluate I_{tot}:

$$I_{\text{tot}} = (2.5\,\text{kg})(0.1\,\text{m})^2 \times \left[\frac{(9.81\,\text{m/s}^2)(6.8\,\text{s})^2}{2(1.8\,\text{m})} - 1\right] = \boxed{3.125\,\text{kg}\cdot\text{m}^2}$$

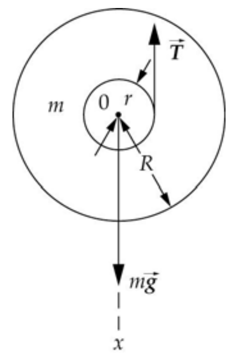
Solve for and evaluate I:

$$I = I_{\text{tot}} - I_0 = 3.125\,\text{kg}\cdot\text{m}^2 - 1.177\,\text{kg}\cdot\text{m}^2 = \boxed{1.948\,\text{kg}\cdot\text{m}^2}$$

Objects Rolling Without Slipping

***79 ••**

Picture the Problem The forces acting on the yo-yo are shown in the figure. We can use a constant-acceleration equation to relate the velocity of descent at the end of the fall to the yo-yo's acceleration and Newton's 2nd law in both translational and rotational form to find the yo-yo's acceleration.



Using a constant-acceleration equation, relate the yo-yo's final speed to its acceleration and fall distance:

$$v^2 = v_0^2 + 2a\Delta h$$

or, because $v_0 = 0$,

$$v = \sqrt{2a\Delta h} \quad (1)$$

Use Newton's 2nd law to relate the forces that act on the yo-yo to its acceleration:

$$\sum F_x = mg - T = ma \quad (2)$$

and

$$\sum \tau_0 = Tr = I_0\alpha \quad (3)$$

Use $a = r\alpha$ to eliminate α in equation (3)

$$Tr = I_0 \frac{a}{r} \quad (4)$$

Eliminate T between equations (2) and (4) to obtain:

$$mg - \frac{I_0}{r^2}a = ma \quad (5)$$

Substitute $\frac{1}{2}mR^2$ for I_0 in equation (5):

$$mg - \frac{\frac{1}{2}mR^2}{r^2}a = ma$$

Solve for a:

$$a = \frac{g}{1 + \frac{R^2}{2r^2}}$$

Substitute numerical values and evaluate a:

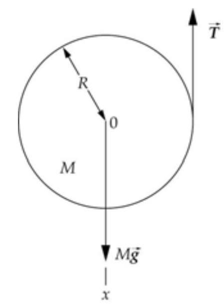
$$a = \frac{9.81\,\text{m/s}^2}{1 + \frac{(1.5\,\text{m})^2}{2(0.1\,\text{m})^2}} = 0.0864\,\text{m/s}^2$$

Substitute in equation (1) and evaluate v:

$$v = \sqrt{2(0.0864\,\text{m/s}^2)(57\,\text{m})} = \boxed{3.14\,\text{m/s}}$$

80 ••

Picture the Problem The diagram shows the forces acting on the cylinder. By applying Newton's 2nd law of motion, we can obtain a system of two equations in the unknowns T, a, and α that we can solve simultaneously.



(*a*) Apply Newton's 2nd law to the cylinder:

$$\sum \tau_0 = TR = I_0\alpha \quad (1)$$

and

$$\sum F_x = Mg - T = Ma \quad (2)$$

Substitute for α and I_0 in equation (1) to obtain:

$$TR = \left(\tfrac{1}{2}MR^2\right)\left(\frac{a}{R}\right)$$

Solve for T:

$$T = \tfrac{1}{2}Ma \quad (3)$$

Substitute for T in equation (2) and solve for a to obtain:

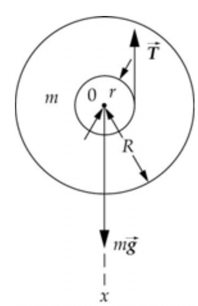
$$a = \boxed{\tfrac{2}{3}g}$$

(*b*) Substitute for a in equation (3) to obtain:

$$T = \tfrac{1}{2}M\left(\tfrac{2}{3}g\right) = \boxed{\tfrac{1}{3}Mg}$$

81 ••

Picture the Problem The forces acting on the yo-yo are shown in the figure. Apply Newton's 2nd law in both translational and rotational form to obtain simultaneous equations in T, a, and α from which we can eliminate α and solve for T and a.



Apply Newton's 2nd law to the yo-yo:

$$\sum F_x = mg - T = ma \quad (1)$$

and

$$\sum \tau_0 = Tr = I_0\alpha \quad (2)$$

Use $a = r\alpha$ to eliminate α in equation (2)

$$Tr = I_0\frac{a}{r} \quad (3)$$

Eliminate T between equations (1) and (3) to obtain:

$$mg - \frac{I_0}{r^2}a = ma \quad (4)$$

Substitute $\frac{1}{2}mR^2$ for I_0 in equation (4):

$$mg - \frac{\frac{1}{2}mR^2}{r^2}a = ma$$

Solve for a:

$$a = \frac{g}{1 + \frac{R^2}{2r^2}}$$

Substitute numerical values and evaluate a:

$$a = \frac{9.81\,\text{m/s}^2}{1 + \frac{(0.1\,\text{m})^2}{2(0.01\,\text{m})^2}} = \boxed{0.192\,\text{m/s}^2}$$

Use equation (1) to solve for and evaluate T:

$$T = m(g - a)$$
$$= (0.1\,\text{kg})(9.81\,\text{m/s}^2 - 0.192\,\text{m/s}^2)$$
$$= \boxed{0.962\,\text{N}}$$

***82 •**

Picture the Problem We can determine the kinetic energy of the cylinder that is due to its rotation about its center of mass by examining the ratio K_{rot}/K.

Express the rotational kinetic energy of the homogeneous solid cylinder:

$$K_{\text{rot}} = \tfrac{1}{2}I_{\text{cyl}}\omega^2 = \tfrac{1}{2}\left(\tfrac{1}{2}mr^2\right)\frac{v^2}{r^2} = \tfrac{1}{4}mv^2$$

Express the total kinetic energy of the homogeneous solid cylinder:

$$K = K_{\text{rot}} + K_{\text{trans}} = \tfrac{1}{4}mv^2 + \tfrac{1}{2}mv^2 = \tfrac{3}{4}mv^2$$

Express the ratio $\frac{K_{\text{rot}}}{K}$:

$$\frac{K_{\text{rot}}}{K} = \frac{\frac{1}{4}mv^2}{\frac{3}{4}mv^2} = \tfrac{1}{3} \text{ and } \boxed{(b)\text{ is correct.}}$$

83 •

Picture the Problem Any work done on the cylinder by a net force will change its kinetic energy. Therefore, the work needed to give the cylinder this motion is equal to its kinetic energy.

Express the relationship between the work needed to stop the cylinder and its kinetic energy:

$$|W| = |\Delta K| = \tfrac{1}{2}mv^2 + \tfrac{1}{2}I\omega^2$$

Because the cylinder is rolling without slipping, its translational and angular speeds are related according to:

$$v = r\omega$$

Substitute for I (see Table 9-1) and ω and simplify to obtain:

$$|W| = \tfrac{1}{2}mv^2 + \tfrac{1}{2}I\omega^2 = \tfrac{1}{2}mv^2 + \tfrac{1}{2}\left(\tfrac{1}{2}mr^2\right)\frac{v^2}{r^2} = \tfrac{3}{4}mv^2$$

Substitute for m and v to obtain:

$$|W| = \tfrac{3}{4}(60\,\text{kg})(5\,\text{m/s})^2 = \boxed{1.13\,\text{kJ}}$$

84 •

Picture the Problem The total kinetic energy of any object that is rolling without slipping is given by $K = K_{\text{trans}} + K_{\text{rot}}$. We can find the percentages associated with each motion by expressing the moment of inertia of the objects as kmr^2 and deriving a general expression for the ratios of rotational kinetic energy to total kinetic energy and translational kinetic energy to total kinetic energy and substituting the appropriate values of k.

Express the total kinetic energy associated with a rotating and translating object:

$$K = K_{\text{trans}} + K_{\text{rot}} = \tfrac{1}{2}mv^2 + \tfrac{1}{2}I\omega^2 = \tfrac{1}{2}mv^2 + \tfrac{1}{2}\left(kmr^2\right)\frac{v^2}{r^2} = \tfrac{1}{2}mv^2 + \tfrac{1}{2}kmv^2 = \tfrac{1}{2}mv^2(1+k)$$

Express the ratio $\dfrac{K_{\text{rot}}}{K}$:

$$\frac{K_{\text{rot}}}{K} = \frac{\tfrac{1}{2}kmv^2}{\tfrac{1}{2}mv^2(1+k)} = \frac{k}{1+k} = \frac{1}{1+\dfrac{1}{k}}$$

Express the ratio $\dfrac{K_{\text{trans}}}{K}$:

$$\frac{K_{\text{trans}}}{K} = \frac{\tfrac{1}{2}mv^2}{\tfrac{1}{2}mv^2(1+k)} = \frac{1}{1+k}$$

(*a*) Substitute $k = 2/5$ for a uniform sphere to obtain:

$$\frac{K_{\text{rot}}}{K} = \frac{1}{1+\dfrac{1}{0.4}} = 0.286 = \boxed{28.6\%}$$

and

$$\frac{K_{\text{trans}}}{K} = \frac{1}{1+0.4} = 0.714 = \boxed{71.4\%}$$

(*b*) Substitute $k = 1/2$ for a uniform cylinder to obtain:

$$\frac{K_{\text{rot}}}{K} = \frac{1}{1+\frac{1}{0.5}} = \boxed{33.3\%}$$

and

$$\frac{K_{\text{trans}}}{K} = \frac{1}{1+0.5} = \boxed{66.7\%}$$

(*c*) Substitute $k = 1$ for a hoop to obtain:

$$\frac{K_{\text{rot}}}{K} = \frac{1}{1+\frac{1}{1}} = \boxed{50.0\%}$$

and

$$\frac{K_{\text{trans}}}{K} = \frac{1}{1+1} = \boxed{50.0\%}$$

85 •

Picture the Problem Let the zero of gravitational potential energy be at the bottom of the incline. As the hoop rolls up the incline its translational and rotational kinetic energies are transformed into gravitational potential energy. We can use energy conservation to relate the distance the hoop rolls up the incline to its total kinetic energy at the bottom of the incline.

Using energy conservation, relate the distance the hoop will roll up the incline to its kinetic energy at the bottom of the incline:

$$\Delta K + \Delta U = 0$$

or, because $K_f = U_i = 0$,

$$-K_i + U_f = 0 \qquad (1)$$

Express K_i as the sum of the translational and rotational kinetic energies of the hoop:

$$K_i = K_{\text{trans}} + K_{\text{rot}} = \tfrac{1}{2}mv^2 + \tfrac{1}{2}I\omega^2$$

When a rolling object moves with speed v, its outer surface turns with a speed v also. Hence $\omega = v/r$. Substitute for I and ω to obtain:

$$K_i = \tfrac{1}{2}mv^2 + \tfrac{1}{2}\left(mr^2\right)\frac{v^2}{r^2} = mv^2$$

Letting Δh be the change in elevation of the hoop as it rolls up the incline and ΔL the distance it rolls along the incline, express U_f:

$$U_f = mg\Delta h = mg\Delta L\sin\theta$$

Substitute in equation (1) to obtain:

$$-mv^2 + mg\Delta L\sin\theta = 0$$

Solve for ΔL:

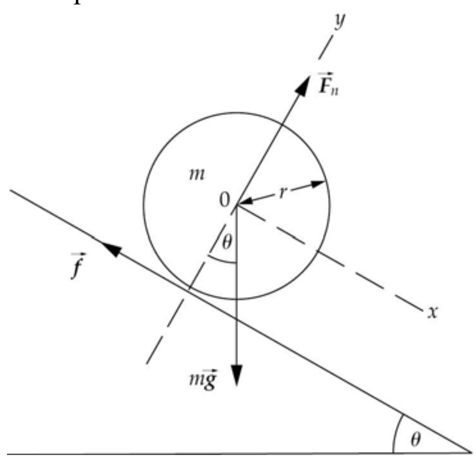
$$\Delta L = \frac{v^2}{g\sin\theta}$$

Substitute numerical values and evaluate ΔL:

$$\Delta L = \frac{(15\,\text{m/s})^2}{(9.81\,\text{m/s}^2)\sin 30°} = \boxed{45.9\,\text{m}}$$

***86 ••**

Picture the Problem From Newton's 2nd law, the acceleration of the center of mass equals the net force divided by the mass. The forces acting on the sphere are its weight $m\vec{g}$ downward, the normal force $\vec{F}_n$ that balances the normal component of the weight, and the force of friction $\vec{f}$ acting up the incline. As the sphere accelerates down the incline, the angular velocity of rotation must increase to maintain the nonslip condition. We can apply Newton's 2nd law for rotation about a horizontal axis through the center of mass of the sphere to find α, which is related to the acceleration by the nonslip condition. The only torque about the center of mass is due to $\vec{f}$ because both $m\vec{g}$ and $\vec{F}_n$ act through the center of mass. Choose the positive direction to be down the incline.



Apply $\sum\vec{F} = m\vec{a}$ to the sphere:

$$mg\sin\theta - f = ma_{cm} \qquad (1)$$

Apply $\sum\tau = I_{cm}\alpha$ to the sphere:

$$fr = I_{cm}\alpha$$

Use the nonslip condition to eliminate α and solve for f:

$$fr = I_{cm}\frac{a_{cm}}{r}$$

and

$$f = \frac{I_{cm}}{r^2}a_{cm}$$

Substitute this result for f in equation (1) to obtain:

$$mg\sin\theta - \frac{I_{cm}}{r^2}a_{cm} = ma_{cm}$$

From Table 9-1 we have, for a solid sphere:

$$I_{cm} = \tfrac{2}{5}mr^2$$

Substitute in equation (1) and simplify to obtain:

$$mg\sin\theta - \tfrac{2}{5}a_{cm} = ma_{cm}$$

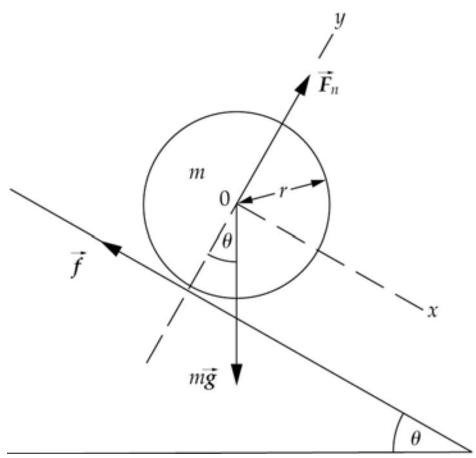
Solve for and evaluate θ:

$$\theta = \sin^{-1}\left(\frac{7a_{cm}}{5g}\right)$$

$$= \sin^{-1}\left[\frac{7(0.2g)}{5g}\right] = \boxed{16.3°}$$

87 ••

Picture the Problem From Newton's 2nd law, the acceleration of the center of mass equals the net force divided by the mass. The forces acting on the thin spherical shell are its weight $m\vec{g}$ downward, the normal force $\vec{F}_n$ that balances the normal component of the weight, and the force of friction $\vec{f}$ acting up the incline. As the spherical shell accelerates down the incline, the angular velocity of rotation must increase to maintain the nonslip condition. We can apply Newton's 2nd law for rotation about a horizontal axis through the center of mass of the sphere to find α, which is related to the acceleration by the nonslip condition. The only torque about the center of mass is due to $\vec{f}$ because both $m\vec{g}$ and $\vec{F}_n$ act through the center of mass. Choose the positive direction to be down the incline.



Apply $\sum\vec{F} = m\vec{a}$ to the thin spherical shell:

$$mg\sin\theta - f = ma_{cm} \qquad (1)$$

Apply $\sum\tau = I_{cm}\alpha$ to the thin spherical shell:

$$fr = I_{cm}\alpha$$

Use the nonslip condition to eliminate α and solve for f:

$$fr = I_{cm}\frac{a_{cm}}{r} \text{ and } f = \frac{I_{cm}}{r^2}a_{cm}$$

Substitute this result for f in equation (1) to obtain:

$$mg\sin\theta - \frac{I_{cm}}{r^2}a_{cm} = ma_{cm}$$

From Table 9-1 we have, for a thin

$$I_{cm} = \tfrac{2}{3}mr^2$$

spherical shell:

Substitute in equation (1) and simplify to obtain:

$$mg\sin\theta - \tfrac{2}{3}a_{cm} = ma_{cm}$$

Solve for and evaluate θ:

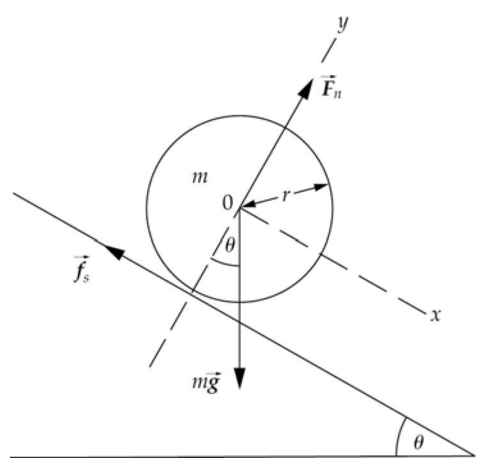
$$\theta = \sin^{-1}\frac{5a_{cm}}{3g}$$

$$= \sin^{-1}\frac{5(0.2g)}{3g} = \boxed{19.5°}$$

Remarks: This larger angle makes sense, as the moment of inertia for a given mass is larger for a hollow sphere than for a solid one.

88 ••

Picture the Problem The three forces acting on the basketball are the weight of the ball, the normal force, and the force of friction. Because the weight can be assumed to be acting at the center of mass, and the normal force acts through the center of mass, the only force which exerts a torque about the center of mass is the frictional force. We can use Newton's 2nd law to find a system of simultaneous equations that we can solve for the quantities called for in the problem statement.



(*a*) Apply Newton's 2nd law in both translational and rotational form to the ball:

$$\sum F_x = mg\sin\theta - f_s = ma, \quad (1)$$

$$\sum F_y = F_n - mg\cos\theta = 0 \quad (2)$$

and

$$\sum \tau_0 = f_s r = I_0\alpha \quad (3)$$

Because the basketball is rolling without slipping we know that:

$$\alpha = \frac{a}{r}$$

Substitute in equation (3) to obtain:

$$f_s r = I_0\frac{a}{r} \quad (4)$$

From Table 9-1 we have:

$$I_0 = \tfrac{2}{3}mr^2$$

Substitute for I_0 and α in equation (4) and solve for f_s:

$$f_s r = \left(\tfrac{2}{3}mr^2\right)\frac{a}{r} \Rightarrow f_s = \tfrac{2}{3}ma \quad (5)$$

Substitute for f_s in equation (1) and solve for a: $a = \boxed{\frac{3}{5} g \sin\theta}$

(*b*) Find f_s using equation (5): $f_s = \frac{2}{3} m\left(\frac{3}{5} g \sin\theta\right) = \boxed{\frac{2}{5} mg \sin\theta}$

(*c*) Solve equation (2) for F_n: $F_n = mg\cos\theta$

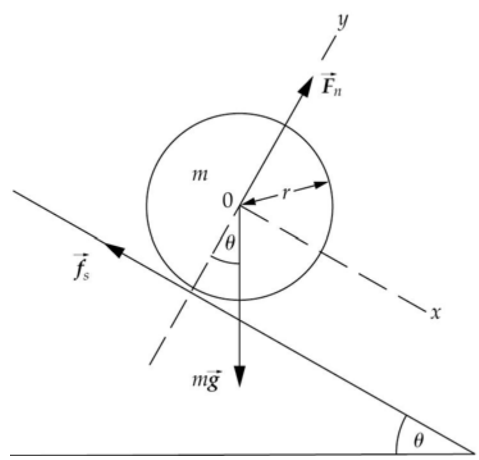
Use the definition of $f_{s,max}$ to obtain: $f_{s,max} = \mu_s F_n = \mu_s mg\cos\theta_{max}$

Use the result of part (*b*) to obtain: $\frac{2}{5} mg \sin\theta_{max} = \mu_s mg\cos\theta_{max}$

Solve for θ_{max}: $\theta_{max} = \boxed{\tan^{-1}\left(\frac{5}{2}\mu_s\right)}$

89 ••

Picture the Problem The three forces acting on the cylinder are the weight of the cylinder, the normal force, and the force of friction. Because the weight can be assumed to be acting at the center of mass, and the normal force acts through the center of mass, the only force which exerts a torque about the center of mass is the frictional force. We can use Newton's 2nd law to find a system of simultaneous equations that we can solve for the quantities called for in the problem statement.



(*a*) Apply Newton's 2nd law in both translational and rotational form to the cylinder:

$$\sum F_x = mg\sin\theta - f_s = ma, \qquad (1)$$

$$\sum F_y = F_n - mg\cos\theta = 0 \qquad (2)$$

and

$$\sum \tau_0 = f_s r = I_0\alpha \qquad (3)$$

Because the cylinder is rolling without slipping we know that: $\alpha = \frac{a}{r}$

Substitute in equation (3) to obtain:

$$f_s r = I_0 \frac{a}{r} \qquad (4)$$

From Table 9-1 we have: $I_0 = \frac{1}{2} mr^2$

Substitute for I_0 and α in equation (4) and solve for f_s:

$$f_s r = \left(\tfrac{1}{2}mr^2\right)\frac{a}{r} \Rightarrow f_s = \tfrac{1}{2}ma \qquad (5)$$

Substitute for f_s in equation (1) and solve for a:

$$a = \boxed{\tfrac{2}{3}g\sin\theta}$$

(*b*) Find f_s using equation (5):

$$f_s = \tfrac{1}{2}m\left(\tfrac{2}{3}g\sin\theta\right) = \boxed{\tfrac{1}{3}mg\sin\theta}$$

(*c*) Solve equation (2) for F_n:

$$F_n = mg\cos\theta$$

Use the definition of $f_{s,max}$ to obtain:

$$f_{s,max} = \mu_s F_n = \mu_s mg\cos\theta_{max}$$

Use the result of part (*b*) to obtain:

$$\tfrac{1}{3}mg\sin\theta_{max} = \mu_s mg\cos\theta_{max}$$

Solve for θ_{max}:

$$\theta_{max} = \boxed{\tan^{-1}(3\mu_s)}$$

***90** ••

Picture the Problem Let the zero of gravitational potential energy be at the elevation where the spheres leave the ramp. The distances the spheres will travel are directly proportional to their speeds when they leave the ramp.

Express the ratio of the distances traveled by the two spheres in terms of their speeds when they leave the ramp:

$$\frac{L'}{L} = \frac{v'\Delta t}{v\Delta t} = \frac{v'}{v} \qquad (1)$$

Use conservation of mechanical energy to find the speed of the spheres when they leave the ramp:

$$\Delta K + \Delta U = 0$$

or, because $K_i = U_f = 0$,

$$K_f - U_i = 0 \qquad (2)$$

Express K_f for the spheres:

$$\begin{aligned} K_f &= K_{trans} + K_{rot} \\ &= \tfrac{1}{2}mv^2 + \tfrac{1}{2}I_{cm}\omega^2 \\ &= \tfrac{1}{2}mv^2 + \tfrac{1}{2}\left(kmR^2\right)\frac{v^2}{R^2} \\ &= \tfrac{1}{2}mv^2 + \tfrac{1}{2}kmv^2 \\ &= (1+k)\tfrac{1}{2}mv^2 \end{aligned}$$

where k is 2/3 for the spherical shell and 2/5 for the uniform sphere.

Substitute in equation (2) to obtain:

$$(1+k)\tfrac{1}{2}mv^2 = mgH$$

Solve for *v*:

$$v=\sqrt{\frac{2gH}{1+k}}$$

Substitute in equation (1) to obtain:

$$\frac{L'}{L}=\sqrt{\frac{1+k}{1+k'}}=\sqrt{\frac{1+\frac{2}{3}}{1+\frac{2}{5}}}=1.09$$

or

$$L'=\boxed{1.09L}$$

91 ••

Picture the Problem Let the subscripts u and h refer to the uniform and thin-walled spheres, respectively. Because the cylinders climb to the same height, their kinetic energies at the bottom of the incline must be equal.

Express the total kinetic energy of the thin-walled cylinder at the bottom of the inclined plane:

$$K_h=K_{trans}+K_{rot}=\tfrac{1}{2}m_hv^2+\tfrac{1}{2}I_h\omega^2$$
$$=\tfrac{1}{2}m_hv^2+\tfrac{1}{2}\left(m_hr^2\right)\frac{v^2}{r^2}=m_hv^2$$

Express the total kinetic energy of the solid cylinder at the bottom of the inclined plane:

$$K_u=K_{trans}+K_{rot}=\tfrac{1}{2}m_uv'^2+\tfrac{1}{2}I_u\omega^2$$
$$=\tfrac{1}{2}m_uv'^2+\tfrac{1}{2}\left(\tfrac{1}{2}m_ur^2\right)\frac{v'^2}{r^2}=\tfrac{3}{4}m_uv'^2$$

Because the cylinders climb to the same height:

$$\tfrac{3}{4}m_uv'^2=m_ugh$$

and

$$m_hv^2=m_hgh$$

Divide the first of these equations by the second:

$$\frac{\tfrac{3}{4}m_uv'^2}{m_hv^2}=\frac{m_ugh}{m_hgh}$$

Simplify to obtain:

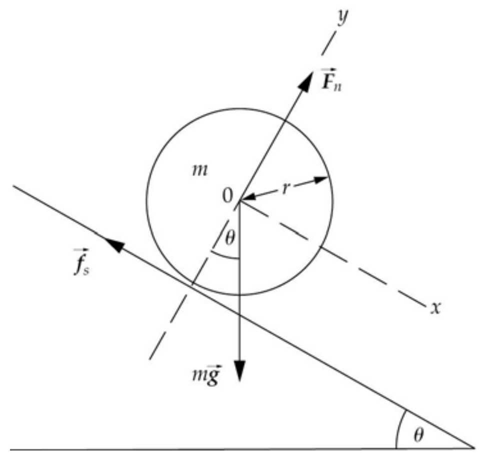
$$\frac{3v'^2}{4v^2}=1$$

Solve for *v*′:

$$v'=\boxed{\sqrt{\frac{4}{3}}v}$$

92 ••

Picture the Problem Let the subscripts s and c refer to the solid sphere and thin-walled cylinder, respectively. Because the cylinder and sphere descend from the same height, their kinetic energies at the bottom of the incline must be equal. The force diagram shows the forces acting on the solid sphere. We'll use Newton's 2nd law to relate the accelerations to the angle of the incline and use a constant acceleration to relate the accelerations to the distances traveled down the incline.



Apply Newton's 2nd law to the sphere:

$$\sum F_x = mg\sin\theta - f_s = ma_s\,, \qquad (1)$$

$$\sum F_y = F_n - mg\cos\theta = 0\,, \qquad (2)$$

and

$$\sum \tau_0 = f_s r = I_0\alpha \qquad (3)$$

Substitute for I_0 and α in equation (3) and solve for f_s:

$$f_s r = \left(\tfrac{2}{5}mr^2\right)\frac{a}{r} \Rightarrow f_s = \tfrac{2}{5}ma_s$$

Substitute for f_s in equation (1) and solve for a:

$$a_s = \tfrac{5}{7}g\sin\theta$$

Proceed as above for the thin-walled cylinder to obtain:

$$a_c = \tfrac{1}{2}g\sin\theta$$

Using a constant-acceleration equation, relate the distance traveled down the incline to its acceleration and the elapsed time:

$$\Delta s = v_0\Delta t + \tfrac{1}{2}a(\Delta t)^2$$

or, because $v_0 = 0$,

$$\Delta s = \tfrac{1}{2}a(\Delta t)^2 \qquad (4)$$

Because Δs is the same for both objects:

$$a_s t_s^2 = a_c t_c^2$$

where

$$t_c^2 = (t_s + 2.4)^2 = t_s^2 + 4.8t_s + 5.76$$

provided t_c and t_s are in seconds.

Substitute for a_s and a_c to obtain the quadratic equation:

$$t_s^2 + 4.8t_s + 5.76 = \tfrac{10}{7}t_s^2$$

Solve for the positive root to obtain: $t_s = 12.3\,\text{s}$

Substitute in equation (4), simplify, and solve for θ:

$$\theta = \sin^{-1}\left[\frac{14\Delta s}{5gt_s^2}\right]$$

Substitute numerical values and evaluate θ:

$$\theta = \sin^{-1}\left[\frac{14(3\,\text{m})}{5(9.81\,\text{m/s}^2)(12.3\,\text{s})^2}\right] = \boxed{0.324°}$$

93 •••

Picture the Problem The kinetic energy of the wheel is the sum of its translational and rotational kinetic energies. Because the wheel is a composite object, we can model its moment of inertia by treating the rim as a cylindrical shell and the spokes as rods.

Express the kinetic energy of the wheel:

$$K = K_{\text{trans}} + K_{\text{rot}} = \tfrac{1}{2}M_{\text{tot}}v^2 + \tfrac{1}{2}I_{\text{cm}}\omega^2 = \tfrac{1}{2}M_{\text{tot}}v^2 + \tfrac{1}{2}I_{\text{cm}}\frac{v^2}{R^2}$$

where $M_{\text{tot}} = M_{\text{rim}} + 4M_{\text{spoke}}$

Express the moment of inertia of the wheel:

$$I_{\text{cm}} = I_{\text{rim}} + I_{\text{spokes}} = M_{\text{rim}}R^2 + 4\left(\tfrac{1}{3}M_{\text{spoke}}R^2\right) = \left(M_{\text{rim}} + \tfrac{4}{3}M_{\text{spoke}}\right)R^2$$

Substitute for I_{cm} in the equation for K:

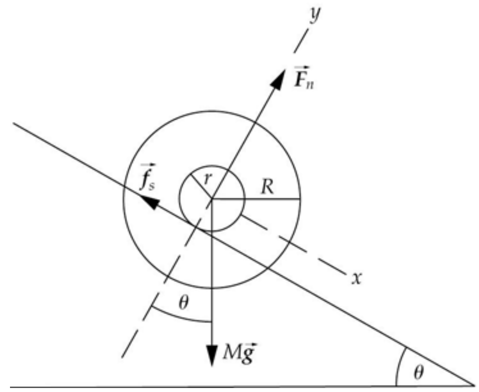
$$K = \tfrac{1}{2}M_{\text{tot}}v^2 + \tfrac{1}{2}\left[\left(M_{\text{rim}} + \tfrac{4}{3}M_{\text{spoke}}\right)R^2\right]\frac{v^2}{R^2} = \left[\tfrac{1}{2}\left(M_{\text{tot}} + M_{\text{rim}}\right) + \tfrac{2}{3}M_{\text{spoke}}\right]v^2$$

Substitute numerical values and evaluate K:

$$K = \left[\tfrac{1}{2}(7.8\,\text{kg} + 3\,\text{kg}) + \tfrac{2}{3}(1.2\,\text{kg})\right](6\,\text{m/s})^2 = \boxed{223\,\text{J}}$$

94 •••

Picture the Problem Let M represent the combined mass of the two disks and their connecting rod and I their moment of inertia. The object's initial potential energy is transformed into translational and rotational kinetic energy as it rolls down the incline. The force diagram shows the forces acting on this composite object as it rolls down the incline. Application of Newton's 2nd law will allow us to derive an expression for the acceleration of the object.



(a) Apply Newton's 2nd law to the disks and rod:

$$\sum F_x = Mg\sin\theta - f_s = Ma\,, \qquad (1)$$

$$\sum F_y = F_n - Mg\cos\theta = 0\,, \qquad (2)$$

and

$$\sum \tau_0 = f_s r = I\alpha \qquad (3)$$

Eliminate f_s and α between equations (1) and (3) and solve for a to obtain:

$$a = \frac{Mg\sin\theta}{M + \dfrac{I}{r^2}} \qquad (4)$$

Express the moment of inertia of the two disks plus connecting rod:

$$I = 2I_{\text{disk}} + I_{\text{rod}} = 2\left(\tfrac{1}{2}m_{\text{disk}}R^2\right) + \tfrac{1}{2}m_{\text{rod}}r^2 = m_{\text{disk}}R^2 + \tfrac{1}{2}m_{\text{rod}}r^2$$

Substitute numerical values and evaluate I:

$$I = (20\,\text{kg})(0.3\,\text{m})^2 + \tfrac{1}{2}(1\,\text{kg})(0.02\,\text{m})^2 = 1.80\,\text{kg}\cdot\text{m}^2$$

Substitute in equation (4) and evaluate a:

$$a = \frac{(41\,\text{kg})(9.81\,\text{m/s}^2)\sin 30°}{41\,\text{kg} + \dfrac{1.80\,\text{kg}\cdot\text{m}^2}{(0.02\,\text{m})^2}} = \boxed{0.0443\,\text{m/s}^2}$$

(b) Find α from a:

$$\alpha = \frac{a}{r} = \frac{0.0443\,\text{m/s}^2}{0.02\,\text{m}} = \boxed{2.21\,\text{rad/s}^2}$$

(*c*) Express the kinetic energy of translation of the disks-plus-rod when it has rolled a distance Δs down the incline:

$$K_{\text{trans}} = \tfrac{1}{2}Mv^2$$

Using a constant-acceleration equation, relate the speed of the disks-plus-rod to their acceleration and the distance moved:

$$v^2 = v_0^2 + 2a\Delta s$$

or, because $v_0 = 0$,

$$v^2 = 2a\Delta s$$

Substitute to obtain:

$$K_{\text{trans}} = Ma\Delta s = (41\,\text{kg})(0.0443\,\text{m/s}^2)(2\,\text{m}) = \boxed{3.63\,\text{J}}$$

(*d*) Express the rotational kinetic energy of the disks after rolling 2 m in terms of their initial potential energy and their translational kinetic energy:

$$K_{\text{rot}} = U_{\text{i}} - K_{\text{trans}} = Mgh - K_{\text{trans}}$$

Substitute numerical values and evaluate K_{rot}:

$$K_{\text{rot}} = (41\,\text{kg})(9.81\,\text{m/s}^2)(2\,\text{m})\sin 30° - 3.63\,\text{J} = \boxed{399\,\text{J}}$$

95 •••

Picture the Problem We can express the coordinates of point *P* as the sum of the coordinates of the center of the wheel and the coordinates, relative to the center of the wheel, of the tip of the vector $\vec{r}_0$. Differentiation of these expressions with respect to time will give us the *x* and *y* components of the velocity of point *P*.

(*a*) Express the coordinates of point *P* relative to the center of the wheel:

$$x = r_0 \cos\theta$$

and

$$y = r_0 \sin\theta$$

Because the coordinates of the center of the circle are *X* and *R*:

$$(x_P, y_P) = \boxed{(X + r_0\cos\theta, R + r_0\sin\theta)}$$

(b) Differentiate x_P to obtain:

$$v_{Px} = \frac{d}{dt}\left(X + r_0 \cos\theta\right) = \frac{dX}{dt} - r_0 \sin\theta \cdot \frac{d\theta}{dt}$$

Note that $\dfrac{dX}{dt} = V$ and $\dfrac{d\theta}{dt} = -\omega = -\dfrac{V}{R}$ so:

$$v_{Px} = \boxed{V + \frac{r_0 V}{R}\sin\theta}$$

Differentiate y_P to obtain:

$$v_{Py} = \frac{d}{dt}\left(R + r_0 \sin\theta\right) = r_0 \cos\theta \cdot \frac{d\theta}{dt}$$

Because $\dfrac{d\theta}{dt} = -\omega = -\dfrac{V}{R}$:

$$v_{Py} = \boxed{-\frac{r_0 V}{R}\cos\theta}$$

(c) Calculate $\vec{\boldsymbol{v}} \cdot \vec{\boldsymbol{r}}$:

$$\vec{\boldsymbol{v}} \cdot \vec{\boldsymbol{r}} = v_{Px} r_x + v_{Py} r_y = \left(V + \frac{r_0 V}{R}\sin\theta\right)\left(r_0 \cos\theta\right) - \left(\frac{r_0 V}{R}\cos\theta\right)\left(R + r_0 \sin\theta\right) = \boxed{0}$$

(d) Express v in terms of its components:

$$v = \sqrt{v_x^2 + v_y^2} = \sqrt{\left(V + \frac{r_0 V}{R}\sin\theta\right)^2 + \left(-\frac{r_0 V}{R}\cos\theta\right)^2} = V\sqrt{1 + 2\frac{r_0}{R}\sin\theta + \frac{r_0^2}{R^2}}$$

Express r in terms of its components:

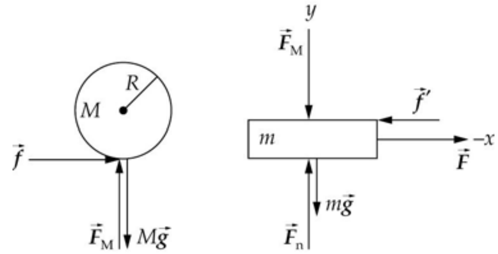
$$r = \sqrt{r_x^2 + r_y^2} = \sqrt{\left(r_0 \cos\theta\right)^2 + \left(R + r_0 \sin\theta\right)^2} = R\sqrt{1 + 2\frac{r_0}{R}\sin\theta + \frac{r_0^2}{R^2}}$$

Divide v by r to obtain:

$$\omega = \frac{v}{r} = \boxed{\frac{V}{R}}$$

***96** •••

Picture the Problem Let the letter B identify the block and the letter C the cylinder. We can find the accelerations of the block and cylinder by applying Newton's 2nd law and solving the resulting equations simultaneously.



Apply $\sum F_x = ma_x$ to the block: $F - f' = ma_B$ (1)

Apply $\sum F_x = ma_x$ to the cylinder: $f = Ma_C$, (2)

Apply $\sum \tau_{CM} = I_{CM}\alpha$ to the cylinder: $fR = I_{CM}\alpha$ (3)

Substitute for I_{CM} in equation (3) and solve for $f = f'$ to obtain: $f = \frac{1}{2}MR\alpha$ (4)

Relate the acceleration of the block to the acceleration of the cylinder:

$a_C = a_B + a_{CB}$

or, because $a_{CB} = -R\alpha$ is the acceleration of the cylinder relative to the block,

$a_C = a_B - R\alpha$

and

$R\alpha = a_B - a_C$ (5)

Equate equations (2) and (4) and substitute from (5) to obtain: $a_B = 3a_C$

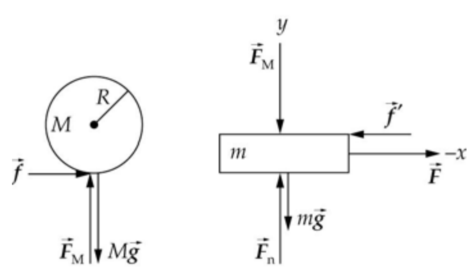
Substitute equation (4) in equation (1) and substitute for a_C to obtain: $F - \frac{1}{3}Ma_B = ma_B$

Solve for a_B:

$$a_B = \boxed{\frac{3F}{M + 3m}}$$

97 •••

Picture the Problem Let the letter B identify the block and the letter C the cylinder. In this problem, as in Problem 97, we can find the accelerations of the block and cylinder by applying Newton's 2nd law and solving the resulting equations simultaneously.



Apply $\sum F_x = ma_x$ to the block: $F - f = ma_\text{B}$ (1)

Apply $\sum F_x = ma_x$ to the cylinder: $f = Ma_\text{C}$, (2)

Apply $\sum \tau_\text{CM} = I_\text{CM}\alpha$ to the cylinder: $fR = I_\text{CM}\alpha$ (3)

Substitute for I_CM in equation (3) and solve for f: $f = \frac{1}{2}MR\alpha$ (4)

Relate the acceleration of the block to the acceleration of the cylinder:

$a_\text{C} = a_\text{B} + a_\text{CB}$

or, because $a_\text{CB} = -R\alpha$,

$a_\text{C} = a_\text{B} - R\alpha$

and

$R\alpha = a_\text{B} - a_\text{C}$ (5)

(*a*) Solve for α and substitute for a_B to obtain:

$$\alpha = \frac{a_\text{B} - a_\text{C}}{R} = \frac{3a_\text{C} - a_\text{C}}{R} = \frac{2a_\text{C}}{R} = \boxed{\frac{2F}{R(M + 3m)}}$$

From the force diagram it is evident that the torque and, therefore, α is in the counterclockwise direction.

(*b*) Equate equations (2) and (4) and substitute (5) to obtain: $a_\text{B} = 3a_\text{C}$

From equations (1) and (4) we obtain: $F - \frac{1}{3}Ma_\text{B} = ma_\text{B}$

Solve for a_B:

$$a_\text{B} = \frac{3F}{M + 3m}$$

Substitute to obtain the linear acceleration of the cylinder relative to the table:

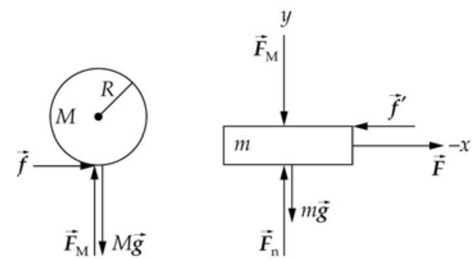
$$a_\text{C} = \frac{1}{3}a_B = \boxed{\frac{F}{M + 3m}}$$

(*c*) Express the acceleration of the cylinder relative to the block:

$$a_{CB} = a_C - a_B = a_C - 3a_C = -2a_C$$
$$= \boxed{-\frac{2F}{M+3m}}$$

98 •••

Picture the Problem Let the system include the earth, the cylinder, and the block. Then $\vec{F}$ is an external force that changes the energy of the system by doing work on it. We can find the kinetic energy of the block from its speed when it has traveled a distance *d*. We can find the kinetic energy of the cylinder from the sum of its translational and rotational kinetic energies. In part (c) we can add the kinetic energies of the block and the cylinder to show that their sum is the work done by $\vec{F}$ in displacing the system a distance *d*.



(*a*) Express the kinetic energy of the block: $K_B = W_{\text{on block}} = \frac{1}{2}mv_B^2$

Using a constant-acceleration equation, relate the velocity of the block to its acceleration and the distance traveled:

$$v_B^2 = v_0^2 + 2a_Bd$$

or, because the block starts from rest,

$$v_B^2 = 2a_Bd$$

Substitute to obtain:

$$K_B = \tfrac{1}{2}m(2a_Bd) = ma_Bd \qquad (1)$$

Apply $\sum F_x = ma_x$ to the block:

$$F - f = ma_B \qquad (2)$$

Apply $\sum F_x = ma_x$ to the cylinder:

$$f = Ma_C\,, \qquad (3)$$

Apply $\sum \tau_{CM} = I_{CM}\alpha$ to the cylinder:

$$fR = I_{CM}\alpha \qquad (4)$$

Substitute for I_{CM} in equation (4) and solve for *f*:

$$f = \tfrac{1}{2}MR\alpha \qquad (5)$$

Relate the acceleration of the block to the acceleration of the cylinder:

$$a_C = a_B + a_{CB}$$

or, because $a_{CB} = -R\alpha$,

$$a_C = a_B - R\alpha$$
and
$$R\alpha = a_B - a_C \qquad (6)$$

Equate equations (3) and (5) and substitute in (6) to obtain:

$$a_B = 3a_C$$

Substitute equation (5) in equation (2) and use $a_B = 3a_C$ to obtain:

$$F - Ma_C = ma_B$$
or
$$F - \tfrac{1}{3}Ma_B = ma_B$$

Solve for a_B:

$$a_B = \frac{F}{m + \frac{1}{3}M}$$

Substitute in equation (1) to obtain:

$$K_B = \boxed{\frac{mFd}{m + \frac{1}{3}M}}$$

(*b*) Express the total kinetic energy of the cylinder:

$$K_{cyl} = K_{trans} + K_{rot} = \tfrac{1}{2}Mv_C^2 + \tfrac{1}{2}I_{CM}\omega^2$$
$$= \tfrac{1}{2}Mv_C^2 + \tfrac{1}{2}I_{CM}\frac{v_{CB}^2}{R^2} \qquad (7)$$
where $v_{CB} = v_C - v_B$.

In part (*a*) it was established that:

$$a_B = 3a_C$$

Integrate both sides of the equation with respect to time to obtain:

$$v_B = 3v_C + \text{constant}$$
where the constant of integration is determined by the initial conditions that $v_C = 0$ when $v_B = 0$.

Substitute the initial conditions to obtain:

$$\text{constant} = 0$$
and
$$v_B = 3v_C$$

Substitute in our expression for v_{CB} to obtain:

$$v_{CB} = v_C - v_B = v_C - 3v_C = -2v_C$$

Substitute for I_{CM} and v_{CB} in equation (7) to obtain:

$$K_{cyl} = \tfrac{1}{2}Mv_C^2 + \tfrac{1}{2}\left(\tfrac{1}{2}MR^2\right)\frac{(-2v_C)^2}{R^2} \qquad (8)$$
$$= \tfrac{3}{2}Mv_C^2$$

Because $v_C = \frac{1}{3}v_B$:

$$v_C^2 = \frac{1}{9}v_B^2$$

It part (*a*) it was established that:

$$v_B^2 = 2a_B d$$

and

$$a_B = \frac{F}{m + \frac{1}{3}M}$$

Substitute to obtain:

$$v_C^2 = \frac{1}{9}(2a_B d) = \frac{2}{9}\left(\frac{F}{m + \frac{1}{3}M}\right)d$$

$$= \frac{2Fd}{9\left(m + \frac{1}{3}M\right)}$$

Substitute in equation (8) to obtain:

$$K_{cyl} = \frac{3}{2}M\left(\frac{2Fd}{9\left(m + \frac{1}{3}M\right)}\right)$$

$$= \boxed{\frac{MFd}{3\left(m + \frac{1}{3}M\right)}}$$

(*c*) Express the total kinetic energy of the system and simplify to obtain:

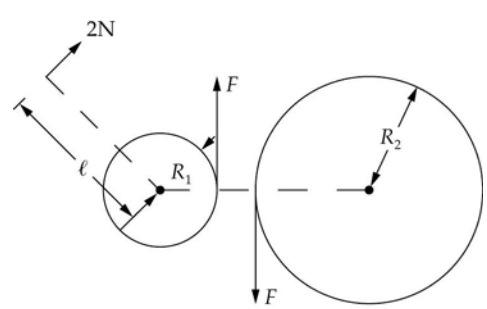
$$K_{tot} = K_B + K_{cyl}$$

$$= \frac{mFd}{m + \frac{1}{3}M} + \frac{MFd}{3\left(m + \frac{1}{3}M\right)}$$

$$= \frac{(3m + M)}{3\left(m + \frac{1}{3}M\right)}Fd = \boxed{Fd}$$

99 ••

Picture the Problem The forces responsible for the rotation of the gears are shown in the diagram to the right. The forces acting through the centers of mass of the two gears have been omitted because they produce no torque. We can apply Newton's 2nd law in rotational form to obtain the equations of motion of the gears and the not slipping condition to relate their angular accelerations.



(*a*) Apply $\sum \tau = I\alpha$ to the gears to obtain their equations of motion:

$$2\text{ N}\cdot\text{m} - FR_1 = I_1\alpha_1 \quad (1)$$

and

$$FR_2 = I_2\alpha_2 \quad (2)$$

where F is the force keeping the gears from slipping with respect to each other.

Because the gears do not slip

$$R_1\alpha_1 = R_2\alpha_2$$

relative to each other, the tangential accelerations of the points where they are in contact must be the same:

or

$$\alpha_2 = \frac{R_1}{R_2}\alpha_1 = \tfrac{1}{2}\alpha_1 \qquad (3)$$

Divide equation (1) by R_1 to obtain:

$$\frac{2\ \text{N}\cdot\text{m}}{R_1} - F = \frac{I_1}{R_1}\alpha_1$$

Divide equation (2) by R_2 to obtain:

$$F = \frac{I_2}{R_2}\alpha_2$$

Add these equations to obtain:

$$\frac{2\ \text{N}\cdot\text{m}}{R_1} = \frac{I_1}{R_1}\alpha_1 + \frac{I_2}{R_2}\alpha_2$$

Use equation (3) to eliminate α_2:

$$\frac{2\ \text{N}\cdot\text{m}}{R_1} = \frac{I_1}{R_1}\alpha_1 + \frac{I_2}{2R_2}\alpha_1$$

Solve for α_1 to obtain:

$$\alpha_1 = \frac{2\ \text{N}\cdot\text{m}}{I_1 + \frac{R_1}{2R_2}I_2}$$

Substitute numerical values and evaluate α_1:

$$\alpha_1 = \frac{2\ \text{N}\cdot\text{m}}{1\,\text{kg}\cdot\text{m}^2 + \frac{0.5\,\text{m}}{2(1\,\text{m})}\left(16\,\text{kg}\cdot\text{m}^2\right)} = \boxed{0.400\,\text{rad/s}^2}$$

Use equation (3) to evaluate α_2:

$$\alpha_2 = \tfrac{1}{2}\left(0.400\,\text{rad/s}^2\right) = \boxed{0.200\,\text{rad/s}^2}$$

(*b*) To counterbalance the 2-N·m torque, a counter torque of 2 N·m must be applied to the first gear. Use equation (2) with $\alpha_1 = 0$ to find F:

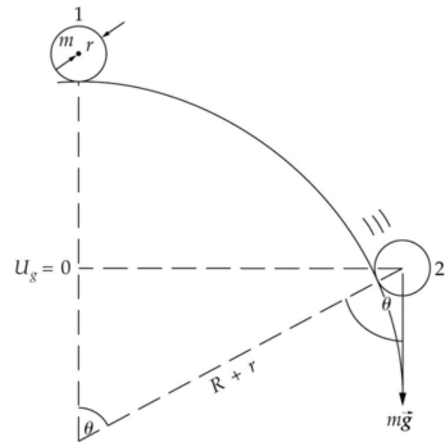
$$2\ \text{N}\cdot\text{m} - FR_1 = 0$$

and

$$F = \frac{2\ \text{N}\cdot\text{m}}{R_1} = \frac{2\ \text{N}\cdot\text{m}}{0.5\,\text{m}} = \boxed{4.00\,\text{N}}$$

***100** ••

Picture the Problem Let r be the radius of the marble, m its mass, R the radius of the large sphere, and v the speed of the marble when it breaks contact with the sphere. The numeral 1 denotes the initial configuration of the sphere-marble system and the numeral 2 is configuration as the marble separates from the sphere. We can use conservation of energy to relate the initial potential energy of the marble to the sum of its translational and rotational kinetic energies as it leaves the sphere. Our choice of the zero of potential energy is shown on the diagram.



(a) Apply conservation of energy:

$$\Delta U + \Delta K = 0$$

or

$$U_2 - U_1 + K_2 - K_1 = 0$$

Because $U_2 = K_1 = 0$:

$$-mg[R + r - (R + r)\cos\theta] + \tfrac{1}{2}mv^2 + \tfrac{1}{2}I\omega^2 = 0$$

or

$$-mg[(R + r)(1 - \cos\theta)] + \tfrac{1}{2}mv^2 + \tfrac{1}{2}I\omega^2 = 0$$

Use the rolling-without-slipping condition to eliminate ω:

$$-mg[(R + r)(1 - \cos\theta)] + \tfrac{1}{2}mv^2 + \tfrac{1}{2}I\frac{v^2}{r^2} = 0$$

From Table 9-1 we have:

$$I = \tfrac{2}{5}mr^2$$

Substitute to obtain:

$$-mg[(R + r)(1 - \cos\theta)] + \tfrac{1}{2}mv^2 + \tfrac{1}{2}\left(\tfrac{2}{5}mr^2\right)\frac{v^2}{r^2} = 0$$

or

$$-mg[(R + r)(1 - \cos\theta)] + \tfrac{1}{2}mv^2 + \tfrac{1}{5}mv^2 = 0$$

Solve for v^2 to obtain:

$$v^2 = \frac{10}{7}g(R + r)(1 - \cos\theta)$$

Apply $\sum F_r = ma_r$ to the marble as it separates from the sphere:

$$mg\cos\theta = m\frac{v^2}{R + r}$$

or

$$\cos\theta = \frac{v^2}{g(R+r)}$$

Substitute for v^2:

$$\cos\theta = \frac{1}{g(R+r)}\left[\frac{10}{7}g(R+r)(1-\cos\theta)\right] = \left[\frac{10}{7}(1-\cos\theta)\right]$$

Solve for and evaluate θ:

$$\theta = \cos^{-1}\left(\frac{10}{17}\right) = \boxed{54.0°}$$

(*b*) The force of friction is always less than μ_s multiplied by the normal force on the marble. However, the normal force decreases to 0 at the point where the ball leaves the sphere, meaning that the force of friction must be less than the force needed to keep the ball rolling without slipping before it leaves the sphere.

Rolling With Slipping

101 •

Picture the Problem Part (*a*) of this problem is identical to Example 9-16. In part (*b*) we can use the definitions of translational and rotational kinetic energy to find the ratio of the final and initial kinetic energies.

(*a*) From Example 9-16:

$$s_1 = \boxed{\frac{12}{49}\frac{v_0^2}{\mu_k g}},$$

$$t_1 = \boxed{\frac{2}{7}\frac{v_0}{\mu_k g}}, \text{ and}$$

$$v_1 = \tfrac{5}{2}\mu_k g t_1 = \boxed{\frac{5}{7}v_0}$$

(*b*) When the ball rolls without slipping, $v_1 = r\omega$. Express the final kinetic energy of the ball:

$$K_f = K_{trans} + K_{rot}$$
$$= \tfrac{1}{2}Mv_1^2 + \tfrac{1}{2}I\omega^2$$
$$= \tfrac{1}{2}Mv_1^2 + \tfrac{1}{2}\left(\tfrac{2}{5}Mr^2\right)\frac{v_1^2}{r^2}$$
$$= \tfrac{7}{10}Mv_1^2 = \tfrac{5}{14}Mv_0^2$$

Express the ratio of the final and initial kinetic energies:

$$\frac{K_f}{K_i}=\frac{\frac{5}{14}Mv_0^2}{\frac{1}{2}Mv_0^2}=\boxed{\frac{5}{7}}$$

(*c*) Substitute in the expressions in (*a*) to obtain:

$$s_1=\frac{12}{49}\frac{(8\,\text{m/s})^2}{(0.06)(9.81\,\text{m/s}^2)}=\boxed{26.6\,\text{m}}$$

$$t_1=\frac{2}{7}\frac{8\,\text{m/s}}{(0.06)(9.81\,\text{m/s}^2)}=\boxed{3.88\,\text{s}}$$

$$v_1=\frac{5}{7}(8\,\text{m/s})=\boxed{5.71\,\text{m/s}}$$

***102 ••**

Picture the Problem The cue stick's blow delivers a rotational impulse as well as a translational impulse to the cue ball. The rotational impulse changes the angular momentum of the ball and the translational impulse changes its linear momentum.

Express the rotational impulse P_{rot} as the product of the average torque and the time during which the rotational impulse acts:

$$P_{rot}=\tau_{av}\Delta t$$

Express the average torque it produces about an axis through the center of the ball:

$$\tau_{av}=P_0(h-r)\sin\theta=P_0(h-r)$$

where θ (= 90°) is the angle between F and the lever arm $h-r$.

Substitute in the expression for P_{rot} to obtain:

$$P_{rot}=P_0(h-r)\Delta t=(P_0\Delta t)(h-r)$$
$$=P_{trams}(h-r)=\Delta L=I\omega_0$$

The translational impulse is also given by:

$$P_{trans}=P_0\Delta t=\Delta p=mv_0$$

Substitute to obtain:

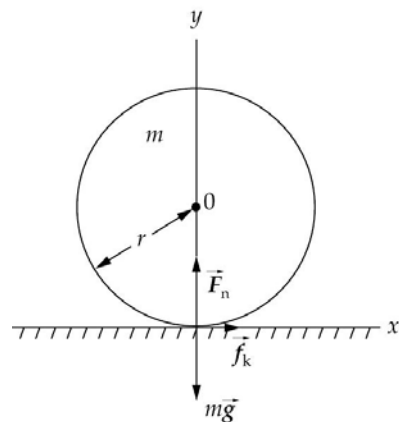
$$mv_0(h-r)=\tfrac{2}{5}mr^2\omega_0$$

Solve for ω_0:

$$\omega_0=\boxed{\frac{5v_0(h-r)}{2r^2}}$$

103 ••

Picture the Problem The angular velocity of the rotating sphere will decrease until the condition for rolling without slipping is satisfied and then it will begin to roll. The force diagram shows the forces acting on the sphere. We can apply Newton's 2nd law to the sphere and use the condition for rolling without slipping to find the speed of the center of mass when the sphere begins to roll without slipping.



Relate the velocity of the sphere when it begins to roll to its acceleration and the elapsed time:

$$v = a\Delta t \quad (1)$$

Apply Newton's 2nd law to the sphere:

$$\sum F_x = f_k = ma\ , \quad (2)$$

$$\sum F_y = F_n - mg = 0\,, \quad (3)$$

and

$$\sum \tau_0 = f_k r = I_0\alpha \quad (4)$$

Using the definition of f_k and F_n from equation (3), substitute in equation (2) and solve for a:

$$a = \mu_k g$$

Substitute in equation (1) to obtain:

$$v = a\Delta t = \mu_k g\Delta t \quad (5)$$

Solve for α in equation (4):

$$\alpha = \frac{f_k r}{I_0} = \frac{mar}{\frac{2}{5}mr^2} = \frac{5}{2}\frac{\mu_k g}{r}$$

Express the angular speed of the sphere when it has been moving for a time Δt:

$$\omega = \omega_0 - \alpha\,\Delta t = \omega_0 - \frac{5\mu_k g}{2r}\Delta t \quad (6)$$

Express the condition that the sphere rolls without slipping:

$$v = r\omega$$

Substitute from equations (5) and (6) and solve for the elapsed time until the sphere begins to roll:

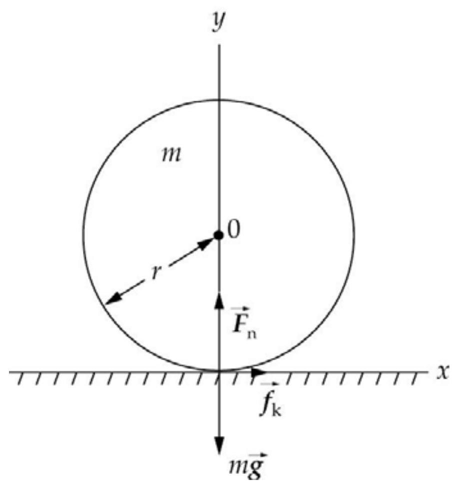
$$\Delta t = \frac{2}{7}\frac{r\omega_0}{\mu_k g}$$

Use equation (4) to find v when the sphere begins to roll:

$$v = \mu_k g\Delta t = \frac{2}{7}\frac{r\omega_0\mu_k g}{\mu_k g} = \boxed{\frac{2r\omega_0}{7}}$$

104 ••

Picture the Problem The sharp force delivers a rotational impulse as well as a translational impulse to the ball. The rotational impulse changes the angular momentum of the ball and the translational impulse changes its linear momentum. In parts (*c*) and (*d*) we can apply Newton's 2nd law to the ball to obtain equations describing both the translational and rotational motion of the ball. We can then solve these equations to find the constant accelerations that allow us to apply constant-acceleration equations to find the velocity of the ball when it begins to roll and its sliding time.



(*a*) Relate the translational impulse delivered to the ball to its change in its momentum:

$$P_{trans} = F_{av}\Delta t = \Delta p = mv_0$$

Solve for v_0:

$$v_0 = \frac{F_{av}\Delta t}{m}$$

Substitute numerical values and evaluate v_0:

$$v_0 = \frac{(20\,kN)(2\times10^{-4}\,s)}{0.02\,kg} = \boxed{200\,m/s}$$

(*b*) Express the rotational impulse P_{rot} as the product of the average torque and the time during which the rotational impulse acts:

$$P_{rot} = \tau_{av}\Delta t$$

Letting h be the height at which the impulsive force is delivered, express the average torque it produces about an axis through the center of the ball:

$$\tau_{av} = F\ell\sin\theta$$

where θ is the angle between F and the lever arm ℓ.

Substitute $h - r$ for ℓ and 90° for θ

$$\tau_{av} = F(h - r)$$

to obtain:

Substitute in the expression for P_{rot} to obtain:

$$P_{\text{rot}} = F(h-r)\Delta t$$

Because $P_{\text{trans}} = F\Delta t$:

$$P_{\text{rot}} = P_{\text{trans}}(h-r) = \Delta L = I\omega_0 = \tfrac{2}{5}mr^2\omega_0$$

Express the translational impulse delivered to the cue ball:

$$P_{\text{trans}} = P_0\Delta t = \Delta p = mv_0$$

Substitute for P_{trans} to obtain:

$$\tfrac{2}{5}mr^2\omega_0 = mv_0$$

Solve for ω_0:

$$\omega_0 = \frac{5v_0(h-r)}{2r^2}$$

Substitute numerical values and evaluate ω_0:

$$\omega_0 = \frac{5(200\,\text{m/s})(0.09\,\text{m}-0.05\,\text{m})}{2(.05\,\text{m})^2} = \boxed{8000\,\text{rad/s}}$$

(*c*) and (*d*) Relate the velocity of the ball when it begins to roll to its acceleration and the elapsed time:

$$v = a\Delta t \qquad (1)$$

Apply Newton's 2nd law to the ball:

$$\sum F_x = f_k = ma\,, \qquad (2)$$

$$\sum F_y = F_n - mg = 0\,, \qquad (3)$$

and

$$\sum \tau_0 = f_k r = I_0\alpha \qquad (4)$$

Using the definition of f_k and F_n from equation (3), substitute in equation (2) and solve for a:

$$a = \mu_k g$$

Substitute in equation (1) to obtain:

$$v = a\Delta t = \mu_k g\Delta t \qquad (5)$$

Solve for α in equation (4):

$$\alpha = \frac{f_k r}{I_0} = \frac{mar}{\tfrac{2}{5}mr^2} = \frac{5}{2}\frac{\mu_k g}{r}$$

Express the angular speed of the ball when it has been moving for a time Δt:

$$\omega = \omega_0 - \alpha\,\Delta t = \omega_0 - \frac{5\mu_k g}{2r}\Delta t \quad (6)$$

Express the speed of the ball when it has been moving for a time Δt:

$$v = v_0 + \mu_k g \Delta t \quad (7)$$

Express the condition that the ball rolls without slipping:

$$v = r\omega$$

Substitute from equations (6) and (7) and solve for the elapsed time until the ball begins to roll:

$$\Delta t = \frac{2}{7}\frac{r\omega_0 - v_0}{\mu_k g}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{2}{7}\left[\frac{(0.05\,\text{m})(8000\,\text{rad/s}) - 200\,\text{m/s}}{(0.5)(9.81\,\text{m/s}^2)}\right] = \boxed{11.6\,\text{s}}$$

Use equation (4) to express v when the ball begins to roll:

$$v = v_0 + \mu_k g \Delta t$$

Substitute numerical values and evaluate v:

$$v = 200\,\text{m/s} + (0.5)(9.81\,\text{m/s}^2)(11.6\,\text{s}) = \boxed{257\,\text{m/s}}$$

105 ••

Picture the Problem Because the impulse is applied through the center of mass, $\omega_0 = 0$. We can use the results of Example 9-16 to find the rolling time without slipping, the distance traveled to rolling without slipping, and the velocity of the ball once it begins to roll without slipping.

(*a*) From Example 9-16 we have:

$$t_1 = \frac{2}{7}\frac{v_0}{\mu_k g}$$

Substitute numerical values and evaluate t_1:

$$t_1 = \frac{2}{7}\frac{4\,\text{m/s}}{(0.6)(9.81\,\text{m/s}^2)} = \boxed{0.194\,\text{s}}$$

(*b*) From Example 9-16 we have:

$$s_1 = \frac{12}{49}\frac{v_0^2}{\mu_k g}$$

Substitute numerical values and evaluate s_1:

$$s_1 = \frac{12}{49}\frac{(4\,\text{m/s})^2}{(0.6)(9.81\,\text{m/s}^2)} = \boxed{0.666\,\text{m}}$$

(*c*) From Example 9-16 we have:

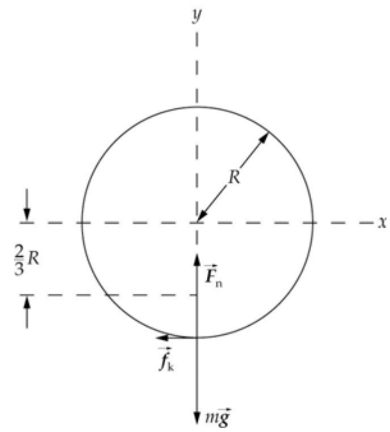
$$v_1 = \frac{5}{7}v_0$$

Substitute numerical values and evaluate v_1:

$$v_1 = \frac{5}{7}(4\,\text{m/s}) = \boxed{2.86\,\text{m/s}}$$

106 ••

Picture the Problem Because the impulsive force is applied below the center line, the spin is backward, i.e., the ball will slow down. We'll use the impulse-momentum theorem and Newton's 2nd law to find the linear and rotational velocities and accelerations of the ball and constant-acceleration equations to relate these quantities to each other and to the elapsed time to rolling without slipping.



(*a*) Express the rotational impulse delivered to the ball:

$$P_{\text{rot}} = mv_0 r = mv_0\frac{2R}{3} = I_{\text{cm}}\omega_0 = \left(\tfrac{2}{5}mR^2\right)\omega_0$$

Solve for ω_0:

$$\omega_0 = \boxed{\frac{5}{3}\frac{v_0}{R}}$$

(*b*) Apply Newton's 2nd law to the ball to obtain:

$$\sum \tau_0 = f_k R = I_{\text{cm}}\alpha\,, \qquad (1)$$

$$\sum F_y = F_n - mg = 0\,, \qquad (2)$$

and

$$\sum F_x = -f_k = ma \qquad (3)$$

Using the definition of f_k and F_n from equation (2), solve for α:

$$\alpha = \frac{\mu_k mgR}{I_{\text{cm}}} = \frac{\mu_k mgR}{\frac{2}{5}mR^2} = \frac{5\mu_k g}{2R}$$

Using a constant-acceleration equation, relate the angular speed of the ball to its acceleration:

$$\omega = \omega_0 + \alpha\Delta t = \omega_0 + \frac{5\mu_k g}{2R}\Delta t$$

Using the definition of f_k and F_n from equation (2), solve equation (3) for a:

$$a = -\mu_k g$$

Using a constant-acceleration equation, relate the speed of the ball to its acceleration:

$$v = v_0 + a\Delta t = v_0 - \mu_k g\Delta t \qquad (4)$$

Impose the condition for rolling without slipping to obtain:

$$R\left(\omega_0 + \frac{5\mu_k g}{2R}\Delta t\right) = v_0 - \mu_k g\Delta t$$

Solve for Δt:

$$\Delta t = \frac{16}{21}\frac{v_0}{\mu_k g}$$

Substitute in equation (4) to obtain:

$$v = v_0 - \mu_k g\left(\frac{16}{21}\frac{v_0}{\mu_k}g\right) = \frac{5}{21}v_0$$

$$= \boxed{0.238v_0}$$

(c) Express the initial kinetic energy of the ball:

$$K_i = K_{trans} + K_{rot} = \tfrac{1}{2}mv_0^2 + \tfrac{1}{2}I\omega_0^2$$

$$= \tfrac{1}{2}mv_0^2 + \tfrac{1}{2}\left(\tfrac{2}{5}mR^2\right)\left(\frac{5v_0}{3R}\right)^2 = \frac{19}{18}mv_0^2$$

$$= \boxed{1.056mv_0^2}$$

(d) Express the work done by friction in terms of the initial and final kinetic energies of the ball:

$$W_{fr} = K_i - K_f$$

Express the final kinetic energy of the ball:

$$K_f = \tfrac{1}{2}mv^2 + \tfrac{1}{2}I_{cm}\omega^2$$

$$= \tfrac{1}{2}mv^2 + \tfrac{1}{2}\left(\tfrac{2}{5}mR^2\right)\frac{v^2}{R^2} = \tfrac{7}{10}mv^2$$

$$= \tfrac{7}{10}m(0.238v_0)^2 = 0.0397mv_0^2$$

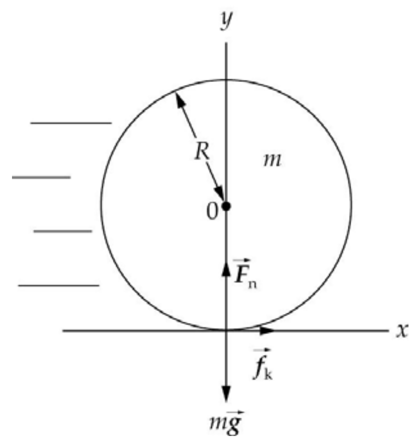
Substitute to find W_{fr}:

$$W_{fr} = 1.056mv_0^2 - 0.0397mv_0^2$$

$$= \boxed{1.016mv_0^2}$$

107 ••

Picture the Problem The figure shows the forces acting on the bowling during the sliding phase of its motion. Because the ball has a forward spin, the friction force is in the direction of motion and will cause the ball's translational speed to increase. We'll apply Newton's 2nd law to find the linear and rotational velocities and accelerations of the ball and constant-acceleration equations to relate these quantities to each other and to the elapsed time to rolling without slipping.



(*a*) and (*b*) Relate the velocity of the ball when it begins to roll to its acceleration and the elapsed time:

$$v = v_0 + a\Delta t \qquad (1)$$

Apply Newton's 2nd law to the ball:

$$\sum F_x = f_k = ma\,, \qquad (2)$$

$$\sum F_y = F_n - mg = 0\,, \qquad (3)$$

and

$$\sum \tau_0 = f_k R = I_0\alpha \qquad (4)$$

Using the definition of f_k and F_n from equation (3), substitute in equation (2) and solve for a:

$$a = \mu_k g$$

Substitute in equation (1) to obtain:

$$v = v_0 + a\Delta t = v_0 + \mu_k g\Delta t \qquad (5)$$

Solve for α in equation (4):

$$\alpha = \frac{f_k R}{I_0} = \frac{maR}{\frac{2}{5}mR^2} = \frac{5}{2}\frac{\mu_k g}{R}$$

Relate the angular speed of the ball to its acceleration:

$$\omega = \omega_0 - \frac{5}{2}\frac{\mu_k g}{R}\Delta t$$

Apply the condition for rolling without slipping:

$$v = R\omega = R\left(\omega_0 - \frac{5}{2}\frac{\mu_k g}{R}\Delta t\right)$$

$$= R\left(\frac{3v_0}{R} - \frac{5}{2}\frac{\mu_k g}{R}\Delta t\right)$$

$$\therefore v = 3v_0 - \frac{5}{2}\mu_k g\Delta t \qquad (6)$$

Equate equations (5) and (6) and solve Δt:

$$\Delta t = \boxed{\frac{4}{7}\frac{v_0}{\mu_k g}}$$

Substitute for Δt in equation (6) to obtain:

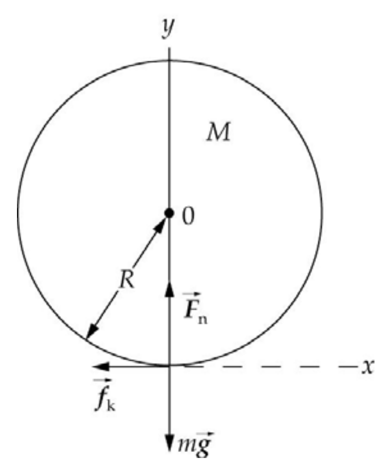
$$v = \frac{11}{7}v_0 = \boxed{1.57v_0}$$

(c) Relate Δx to the average speed of the ball and the time it moves before beginning to roll without slipping:

$$\Delta x = v_{av}\Delta t = \tfrac{1}{2}(v_0 + v)\Delta t$$
$$= \tfrac{1}{2}\left(v_0 + \frac{11}{7}v_0\right)\left(\frac{4v_0}{7\mu_k g}\right)$$
$$= \frac{36}{49}\frac{v_0^2}{\mu_k g} = \boxed{0.735\frac{v_0^2}{\mu_k g}}$$

***108 ••**

Picture the Problem The figure shows the forces acting on the cylinder during the sliding phase of its motion. The friction force will cause the cylinder's translational speed to decrease and eventually satisfy the condition for rolling without slipping. We'll use Newton's 2nd law to find the linear and rotational velocities and accelerations of the ball and constant-acceleration equations to relate these quantities to each other and to the distance traveled and the elapsed time until the satisfaction of the condition for rolling without slipping.



(a) Apply Newton's 2nd law to the cylinder:

$$\sum F_x = -f_k = Ma, \qquad (1)$$
$$\sum F_y = F_n - Mg = 0, \qquad (2)$$

and

$$\sum \tau_0 = f_k R = I_0\alpha \qquad (3)$$

Use $f_k = \mu_k F_n$ to eliminate F_n between equations (1) and (2) and solve for a:

$$a = -\mu_k g$$

Using a constant-acceleration equation, relate the speed of the cylinder to its acceleration and the elapsed time:

$$v = v_0 + a\Delta t = v_0 - \mu_k g\Delta t$$

Similarly, eliminate f_k between equations (2) and (3) and solve for α:

$$\alpha = \frac{2\mu_k g}{R}$$

Using a constant-acceleration equation, relate the angular speed of the cylinder to its acceleration and the elapsed time:

$$\omega = \omega_0 + \alpha\Delta t = \frac{2\mu_k g}{R}\Delta t$$

Apply the condition for rolling without slipping:

$$v = v_0 - \mu_k g\Delta t = R\omega = R\left(\frac{2\mu_k g}{R}\Delta t\right)$$
$$= 2\mu_k g\Delta t$$

Solve for Δt:

$$\Delta t = \frac{v_0}{3\mu_k g}$$

Substitute for Δt in the expression for v:

$$v = v_0 - \mu_k g\frac{v_0}{3\mu_k g} = \boxed{\frac{2}{3}v_0}$$

(*b*) Relate the distance the cylinder travels to its average speed and the elapsed time:

$$\Delta x = v_{av}\Delta t = \tfrac{1}{2}\left(v_0 + \tfrac{2}{3}v_0\right)\left(\frac{v_0}{3\mu_k g}\right)$$
$$= \boxed{\frac{5}{18}\frac{v_0^2}{\mu_k g}}$$

(*c*) Express the ratio of the energy dissipated in friction to the cylinder's initial mechanical energy:

$$\frac{W_{fr}}{K_i} = \frac{K_i - K_f}{K_i}$$

Express the kinetic energy of the cylinder as it begins to roll without slipping:

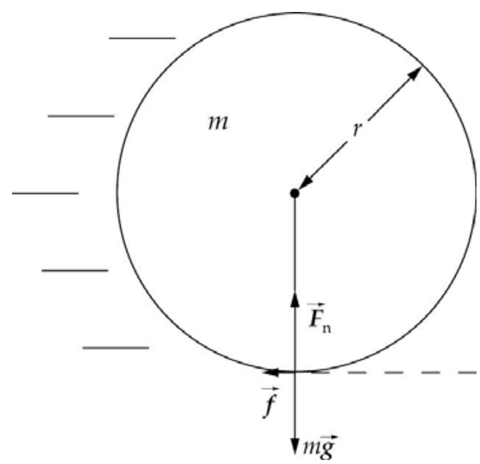
$$K_f = \tfrac{1}{2}Mv^2 + \tfrac{1}{2}I_{cm}\omega^2$$
$$= \tfrac{1}{2}Mv^2 + \tfrac{1}{2}\left(\tfrac{1}{2}MR^2\right)\frac{v^2}{R^2}$$
$$= \frac{3}{4}Mv^2 = \frac{3}{4}M\left(\frac{2}{3}v_0\right)^2 = \frac{1}{3}Mv_0^2$$

Substitute for K_i and K_f and simplify to obtain:

$$\frac{W_{fr}}{K_i} = \frac{\frac{1}{2}Mv_0^2 - \frac{1}{3}Mv_0^2}{\frac{1}{2}Mv_0^2} = \boxed{\frac{1}{3}}$$

109 ••

Picture the Problem The forces acting on the ball as it slides across the floor are its weight $m\vec{g}$, the normal force $\vec{F}_n$ exerted by the floor, and the friction force $\vec{f}$. Because the weight and normal force act through the center of mass of the ball and are equal in magnitude, the friction force is the net (decelerating) force. We can apply Newton's 2nd law in both translational and rotational form to obtain a set of equations that we can solve for the acceleration of the ball. Once we have determined the ball's acceleration, we can use constant-acceleration equations to obtain its velocity when it begins to roll without slipping.



(*a*) Apply $\sum \vec{F} = m\vec{a}$ to the ball:

$$\sum F_x = -f = ma \quad (1)$$

and

$$\sum F_y = F_n - mg = 0 \quad (2)$$

From the definition of the coefficient of kinetic friction we have:

$$f = \mu_k F_n \quad (3)$$

Solve equation (2) for F_n:

$$F_n = mg$$

Substitute in equation (3) to obtain:

$$f = \mu_k mg$$

Substitute in equation (1) to obtain:

$$-\mu_k mg = ma$$

or

$$a = -\mu_k g$$

Apply $\sum \tau = I\alpha$ to the ball:

$$fr = I\alpha$$

Solve for α to obtain:

$$\alpha = \frac{fr}{I} = \frac{\mu_k mgr}{I}$$

Assuming that the coefficient of kinetic friction is constant*, we can use constant-acceleration equations to describe how long it will take the ball to begin

$$v_f - v = a\Delta t = -\mu_k g\Delta t \quad (4)$$

and

$$\omega_f = \frac{\mu_k gmr}{I}\Delta t \quad (5)$$

rolling without slipping:

Once rolling without slipping has been established, we also have:

$$\omega_{\text{f}} = \frac{v_{\text{f}}}{r} \qquad (6)$$

Equate equations (5) and (6):

$$\frac{v_{\text{f}}}{r} = \frac{\mu_k gmr}{I}\Delta t$$

Solve for Δt:

$$\Delta t = \frac{v_{\text{f}} I}{\mu_k gmr^2}$$

Substitute in equation (4) to obtain:

$$v_{\text{f}} - v = -\mu_k g\left(\frac{v_{\text{f}} I}{\mu_k gmr^2}\right)$$

$$= -\frac{I}{mr^2}v_{\text{f}}$$

Solve for v_{f}:

$$v_f = \boxed{\frac{1}{1+\frac{I}{mr^2}}v}$$

(*b*) Express the total kinetic energy of the ball:

$$K = \frac{1}{2}mv_{\text{f}}^2 + \frac{1}{2}I\omega_{\text{f}}^2$$

Because the ball is now rolling without slipping, $v = r\omega_{\text{f}}$ and:

$$K = \frac{1}{2}m\left(\frac{1}{1+I/mr^2}\right)^2 v^2 + \frac{1}{2}I\left(\frac{1}{1+I/mr^2}\right)^2 \frac{v^2}{r^2} = \frac{1}{2}mv^2\left(\left(1+I/mr^2\right)\left(\frac{1}{1+I/mr^2}\right)^2\right)$$

$$= \boxed{\frac{1}{2}mv^2\left(\frac{1}{1+I/mr^2}\right)}$$

*** Remarks: This assumption is not necessary. One can use the impulse-momentum theorem and the related theorem for torque and change in angular momentum to prove that the result holds for an *arbitrary* frictional force acting on the ball, so long as the ball moves along a straight line and the force is directed opposite to the direction of motion of the ball.**

General Problems

***110** •

Picture the Problem The angular velocity of an object is the ratio of the number of revolutions it makes in a given period of time to the elapsed time.

The moon's angular velocity is:

$$\omega = \frac{1\,\text{rev}}{27.3\,\text{days}}$$
$$= \frac{1\,\text{rev}}{27.3\,\text{days}} \times \frac{2\pi\,\text{rad}}{\text{rev}} \times \frac{1\,\text{day}}{24\,\text{h}} \times \frac{1\,\text{h}}{3600\,\text{s}}$$
$$= \boxed{2.66\times10^{-6}\ \text{rad/s}}$$

111 •

Picture the Problem The moment of inertia of the hoop, about an axis perpendicular to the plane of the hoop and through its edge, is related to its moment of inertia with respect to an axis through its center of mass by the parallel axis theorem.

Apply the parallel axis theorem:

$$I = I_{\text{cm}} + Mh^2 = MR^2 + MR^2 = \boxed{2mR^2}$$

112 ••

Picture the Problem The force you exert on the rope results in a net torque that accelerates the merry-go-round. The moment of inertia of the merry-go-round, its angular acceleration, and the torque you apply are related through Newton's 2nd law.

(*a*) Using a constant-acceleration equation, relate the angular displacement of the merry-go-round to its angular acceleration and acceleration time:

$$\Delta\theta = \omega_0\Delta t + \tfrac{1}{2}\alpha(\Delta t)^2$$

or, because $\omega_0 = 0$,

$$\Delta\theta = \tfrac{1}{2}\alpha(\Delta t)^2$$

Solve for and evaluate α:

$$\alpha = \frac{2\Delta\theta}{(\Delta t)^2} = \frac{2(2\pi\,\text{rad})}{(12\,\text{s})^2} = \boxed{0.0873\,\text{rad/s}^2}$$

(*b*) Use the definition of torque to obtain:

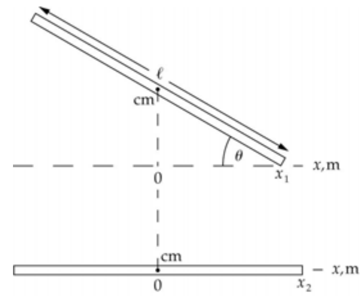
$$\tau = Fr = (260\,\text{N})(2.2\,\text{m}) = \boxed{572\,\text{N}\cdot\text{m}}$$

(*c*) Use Newton's 2nd law to find the moment of inertia of the merry-go-round:

$$I = \frac{\tau_{\text{net}}}{\alpha} = \frac{572\,\text{N}\cdot\text{m}}{0.0873\,\text{rad/s}^2}$$
$$= \boxed{6.55\times10^3\ \text{kg}\cdot\text{m}^2}$$

113 •

Picture the Problem Because there are no horizontal forces acting on the stick, the center of mass of the stick will not move in the horizontal direction. Choose a coordinate system in which the origin is at the horizontal position of the center of mass. The diagram shows the stick in its initial raised position and when it has fallen to the ice.



Express the displacement of the right end of the stick Δx as the difference between the position coordinates x_2 and x_2:

$$\Delta x = x_2 - x_1$$

Using trigonometry, find the initial coordinate of the right end of the stick:

$$x_1 = \ell\cos\theta = (1\,\text{m})\cos 30° = 0.866\,\text{m}$$

Because the center of mass has not moved horizontally:

$$x_2 = \ell = 1\,\text{m}$$

Substitute to find the displacement of the right end of the stick:

$$\Delta x = 1\,\text{m} - 0.866\,\text{m} = \boxed{0.134\,\text{m}}$$

114 ••

Picture the Problem The force applied to the string results in a torque about the center of mass of the disk that accelerates it. We can relate these quantities to the moment of inertia of the disk through Newton's 2nd law and then use constant-acceleration equations to find the disk's angular velocity the angle through which it has rotated in a given period of time. The disk's rotational kinetic energy can be found from its definition.

(*a*) Use the definition of torque to obtain:

$$\tau \equiv FR = (20\,\text{N})(0.12\,\text{m}) = \boxed{2.40\,\text{N}\cdot\text{m}}$$

(*b*) Use Newton's 2nd law to express the angular acceleration of the disk in terms of the net torque acting on it and its moment of inertia:

$$\alpha = \frac{\tau_{\text{net}}}{I} = \frac{\tau_{\text{net}}}{\frac{1}{2}MR^2}$$

Substitute numerical values and evaluate α:

$$\alpha = \frac{2(2.40\,\text{N}\cdot\text{m})}{(5\,\text{kg})(0.12\,\text{m})^2} = \boxed{66.7\,\text{rad/s}^2}$$

(*c*) Using a constant-acceleration equation, relate the angular velocity of the disk to its angular

$$\omega = \omega_0 + \alpha\Delta t$$

or, because $\omega_0 = 0$,

$$\omega = \alpha\Delta t$$

acceleration and the elapsed time:

Substitute numerical values and evaluate ω:

$$\omega = \left(66.7\,\text{rad/s}^2\right)\left(5\,\text{s}\right) = \boxed{333\,\text{rad/s}}$$

(d) Use the definition of rotational kinetic energy to obtain:

$$K_{\text{rot}} = \tfrac{1}{2}I\omega^2 = \tfrac{1}{2}\left(\tfrac{1}{2}MR^2\right)\omega^2$$

Substitute numerical values and evaluate K_{rot}:

$$K_{\text{rot}} = \tfrac{1}{4}\left(5\,\text{kg}\right)\left(0.12\,\text{m}\right)^2\left(333\,\text{rad/s}\right)^2 = \boxed{2.00\,\text{kJ}}$$

(e) Using a constant-acceleration equation, relate the angle through which the disk turns to its angular acceleration and the elapsed time:

$$\Delta\theta = \omega_0\Delta t + \tfrac{1}{2}\alpha\left(\Delta t\right)^2$$

or, because $\omega_0 = 0$,

$$\Delta\theta = \tfrac{1}{2}\alpha\left(\Delta t\right)^2$$

Substitute numerical values and evaluate $\Delta\theta$:

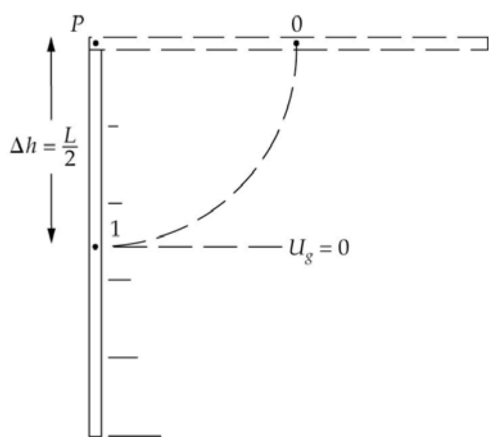
$$\Delta\theta = \tfrac{1}{2}\left(66.7\,\text{rad/s}^2\right)\left(5\,\text{s}\right)^2 = \boxed{834\,\text{rad}}$$

(f) Express K in terms of τ and θ:

$$K = \tfrac{1}{2}I\omega^2 = \tfrac{1}{2}\left(\frac{\tau}{\alpha}\right)\left(\alpha\Delta t\right)^2 = \tfrac{1}{2}\alpha\tau\left(\Delta t\right)^2 = \boxed{\tau\,\Delta\theta}$$

115 ••

Picture the Problem The diagram shows the rod in its initial horizontal position and then, later, as it swings through its vertical position. The center of mass is denoted by the numerals 0 and 1. Let the length of the rod be represented by L and its mass by m. We can use Newton's 2nd law in rotational form to find, first, the angular acceleration of the rod and then, from α, the acceleration of any point on the rod. We can use conservation of energy to find the angular velocity of the center of mass of the rod when it is vertical and then use this value to find its linear velocity.



(a) Relate the acceleration of the center of the rod to the angular

$$a = \ell\alpha = \frac{L}{2}\alpha$$

acceleration of the rod:

Use Newton's 2nd law to relate the torque about the suspension point of the rod (exerted by the weight of the rod) to the rod's angular acceleration:

$$\alpha = \frac{\tau}{I} = \frac{Mg\frac{L}{2}}{\frac{1}{3}ML^2} = \frac{3g}{2L}$$

Substitute numerical values and evaluate α:

$$\alpha = \frac{3(9.81\,\text{m/s}^2)}{2(0.8\,\text{m})} = 18.4\,\text{rad/s}^2$$

Substitute numerical values and evaluate a:

$$a = \tfrac{1}{2}(0.8\,\text{m})(18.4\,\text{rad/s}^2) = \boxed{7.36\,\text{m/s}^2}$$

(*b*) Relate the acceleration of the end of the rod to α:

$$a_{\text{end}} = L\alpha = (0.8\,\text{m})(18.4\,\text{rad/s}^2) = \boxed{14.7\,\text{m/s}^2}$$

(*c*) Relate the linear velocity of the center of mass of the rod to its angular velocity as it passes through the vertical:

$$v = \omega\Delta h = \tfrac{1}{2}\omega L$$

Use conservation of energy to relate the changes in the kinetic and potential energies of the rod as it swings from its initial horizontal orientation through its vertical orientation:

$$\Delta K + \Delta U = K_1 - K_0 + U_1 - U_0 = 0$$

or, because $K_0 = U_1 = 0$,

$$K_1 - U_0 = 0$$

Substitute to obtain:

$$\tfrac{1}{2} I_P\omega^2 = mg\Delta h$$

Substitute for Δh and solve for ω:

$$\omega = \sqrt{\frac{3g}{L}}$$

Substitute to obtain:

$$v = \tfrac{1}{2}L\sqrt{\frac{3g}{L}} = \tfrac{1}{2}\sqrt{3gL}$$

Substitute numerical values and evaluate v:

$$v = \tfrac{1}{2}\sqrt{3(9.81\,\text{m/s}^2)(0.8\,\text{m})} = \boxed{2.43\,\text{m/s}}$$

116 ••

Picture the Problem Let the zero of gravitational potential energy be at the bottom of the track. The initial potential energy of the marble is transformed into translational and rotational kinetic energy as it rolls down the track to its lowest point and then, because the portion of the track to the right is frictionless, into translational kinetic energy and, eventually, into gravitational potential energy.

Using conservation of energy, relate h_2 to the kinetic energy of the marble at the bottom of the track:

$$\Delta K + \Delta U = 0$$

or, because $K_f = U_i = 0$,

$$-K_i + U_f = 0$$

Substitute for K_i and U_f to obtain:

$$-\tfrac{1}{2}Mv^2 - Mgh_2 = 0$$

Solve for h_2:

$$h_2 = \frac{v^2}{2g} \qquad (1)$$

Using conservation of energy, relate h_1 to the kinetic energy of the marble at the bottom of the track:

$$\Delta K + \Delta U = 0$$

or, because $K_i = U_f = 0$,

$$K_f - U_i = 0$$

Substitute for K_f and U_i to obtain:

$$\tfrac{1}{2}Mv^2 + \tfrac{1}{2}I\omega^2 - Mgh_1 = 0$$

Substitute for I and solve for v^2 to obtain:

$$v^2 = \tfrac{10}{7}gh_1$$

Substitute in equation (1) to obtain:

$$h_2 = \frac{\tfrac{10}{7}gh_1}{2g} = \boxed{\tfrac{5}{7}h_1}$$

***117** ••

Picture the Problem To stop the wheel, the tangential force will have to do an amount of work equal to the initial rotational kinetic energy of the wheel. We can find the stopping torque and the force from the average power delivered by the force during the slowing of the wheel. The number of revolutions made by the wheel as it stops can be found from a constant-acceleration equation.

(*a*) Relate the work that must be done to stop the wheel to its kinetic energy:

$$W = \tfrac{1}{2}I\omega^2 = \tfrac{1}{2}\left(\tfrac{1}{2}mr^2\right)\omega^2 = \tfrac{1}{4}mr^2\omega^2$$

Substitute numerical values and evaluate W:

$$W = \tfrac{1}{4}(120\,\text{kg})(1.4\,\text{m})^2 \times \left[1100\frac{\text{rev}}{\text{min}} \times \frac{2\pi\,\text{rad}}{\text{rev}} \times \frac{1\,\text{min}}{60\,\text{s}}\right]^2 = \boxed{780\,\text{kJ}}$$

(*b*) Express the stopping torque is terms of the average power required:

$$P_{\text{av}} = \tau\omega_{\text{av}}$$

Solve for τ:

$$\tau = \frac{P_{\text{av}}}{\omega_{\text{av}}}$$

Substitute numerical values and evaluate τ:

$$\tau = \frac{\dfrac{780\,\text{kJ}}{(2.5\,\text{min})(60\,\text{s/min})}}{\dfrac{(1100\,\text{rev/min})(2\pi\,\text{rad/rev})(1\,\text{min}/60\,\text{s})}{2}} = \boxed{90.3\,\text{N}\cdot\text{m}}$$

Relate the stopping torque to the magnitude of the required force and solve for F:

$$F = \frac{\tau}{R} = \frac{90.3\,\text{N}\cdot\text{m}}{0.6\,\text{m}} = \boxed{151\text{ N}}$$

(*c*) Using a constant-acceleration equation, relate the angular displacement of the wheel to its average angular velocity and the stopping time:

$$\Delta\theta = \omega_{\text{av}}\Delta t$$

Substitute numerical values and evaluate $\Delta\theta$:

$$\Delta\theta = \left(\frac{1100\,\text{rev/min}}{2}\right)(2.5\,\text{min}) = \boxed{1380\,\text{rev}}$$

118 ••

Picture the Problem The work done by the four children on the merry-go-round will change its kinetic energy. We can use the work-energy theorem to relate the work done by the children to the distance they ran and Newton's 2^{nd} law to find the angular acceleration of the merry-go-round.

(*a*) Use the work-kinetic energy theorem to relate the work done by the children to the kinetic energy of the merry-go-round:

$$W_{\text{net force}} = \Delta K = K_f$$

or

$$4F\Delta s = \tfrac{1}{2}I\omega^2$$

Substitute for I and solve for Δs to obtain:

$$\Delta s = \frac{I\omega^2}{8F} = \frac{\frac{1}{2}mr^2\omega^2}{8F} = \frac{mr^2\omega^2}{16F}$$

Substitute numerical values and evaluate Δs:

$$\Delta s = \frac{(240\,\text{kg})(2\,\text{m})^2\left[\frac{1\,\text{rev}}{2.8\,\text{s}}\times\frac{2\pi\,\text{rad}}{\text{rev}}\right]^2}{16(26\,\text{N})} = \boxed{11.6\,\text{m}}$$

(*b*) Apply Newton's 2nd law to express the angular acceleration of the merry-go-round:

$$\alpha = \frac{\tau_{\text{net}}}{I} = \frac{4Fr}{\frac{1}{2}mr^2} = \frac{8F}{mr}$$

Substitute numerical values and evaluate α:

$$\alpha = \frac{8(26\,\text{N})}{(240\,\text{kg})(2\,\text{m})} = \boxed{0.433\,\text{rad/s}^2}$$

(*c*) Use the definition of work to relate the force exerted by each child to the distance over which that force is exerted:

$$W = F\Delta s = (26\,\text{N})(11.6\,\text{m}) = \boxed{302\,\text{J}}$$

(*d*) Relate the kinetic energy of the merry-go-round to the work that was done on it:

$$W_{\text{net force}} = \Delta K = K_f - 0 = 4F\Delta s$$

Substitute numerical values and evaluate $W_{\text{net force}}$:

$$W_{\text{net force}} = 4(26\,\text{N})(11.6\,\text{m}) = \boxed{1.21\,\text{kJ}}$$

119 ••

Picture the Problem Because the center of mass of the hoop is at its center, we can use Newton's second law to relate the acceleration of the hoop to the net force acting on it. The distance moved by the center of the hoop can be determined using a constant-acceleration equation, as can the angular velocity of the hoop.

(*a*) Using a constant-acceleration equation, relate the distance the

$$\Delta s = \tfrac{1}{2}a_{\text{cm}}(\Delta t)^2$$

center of the travels in 3 s to the acceleration of its center of mass:

Relate the acceleration of the center of mass of the hoop to the net force acting on it:

$$a_{\text{cm}} = \frac{F_{\text{net}}}{m}$$

Substitute to obtain:

$$\Delta s = \frac{F(\Delta t)^2}{2m}$$

Substitute numerical values and evaluate Δs:

$$\Delta s = \frac{(5\,\text{N})(3\,\text{s})^2}{2(1.5\,\text{kg})} = \boxed{15.0\,\text{m}}$$

(*b*) Relate the angular velocity of the hoop to its angular acceleration and the elapsed time:

$$\omega = \alpha\,\Delta t$$

Use Newton's 2nd law to relate the angular acceleration of the hoop to the net torque acting on it:

$$\alpha = \frac{\tau_{\text{net}}}{I} = \frac{FR}{mR^2} = \frac{F}{mR}$$

Substitute to obtain:

$$\omega = \frac{F\Delta t}{mR}$$

Substitute numerical values and evaluate ω:

$$\omega = \frac{(5\,\text{N})(3\,\text{s})}{(1.5\,\text{kg})(0.65\,\text{m})} = \boxed{15.4\,\text{rad/s}}$$

120 ••

Picture the Problem Let R represent the radius of the grinding wheel, M its mass, r the radius of the handle, and m the mass of the load attached to the handle. In the absence of information to the contrary, we'll treat the 25-kg load as though it were concentrated at a point. Let the zero of gravitational potential energy be where the 25-kg load is at its lowest point. We'll apply Newton's 2nd law and the conservation of mechanical energy to determine the initial angular acceleration and the maximum angular velocity of the wheel.

(*a*) Use Newton's 2nd law to relate the acceleration of the wheel to the net torque acting on it:

$$\alpha = \frac{\tau_{\text{net}}}{I} = \frac{mgr}{\frac{1}{2}MR^2 + mr^2}$$

Substitute numerical values and evaluate α:

$$\alpha = \frac{(25\,\text{kg})(9.81\,\text{m/s}^2)(0.65\,\text{m})}{\frac{1}{2}(60\,\text{kg})(0.45\,\text{m})^2 + (25\,\text{kg})(0.65\,\text{m})^2} = \boxed{9.58\,\text{rad/s}^2}$$

(*b*) Use the conservation of mechanical energy to relate the initial potential energy of the load to its kinetic energy and the rotational kinetic energy of the wheel when the load is directly below the center of mass of the wheel:

$$\Delta K + \Delta U = 0$$

or, because $K_i = U_f = 0$,

$$K_{\text{f,trans}} + K_{\text{f,rot}} - U_i = 0\,.$$

Substitute and solve for ω:

$$\tfrac{1}{2}mv^2 + \tfrac{1}{2}\left(\tfrac{1}{2}MR^2\right)\omega^2 - mgr = 0\,,$$

$$\tfrac{1}{2}mr^2\omega^2 + \tfrac{1}{4}MR^2\omega^2 - mgr = 0\,,$$

and

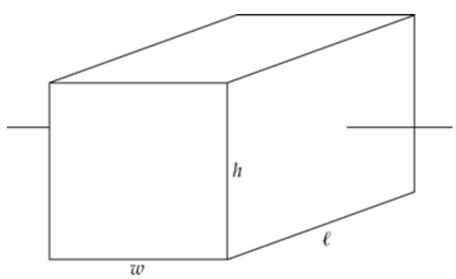
$$\omega = \sqrt{\frac{4mgr}{2mr^2 + MR^2}}$$

Substitute numerical values and evaluate ω:

$$\omega = \sqrt{\frac{4(25\,\text{kg})(9.81\,\text{m/s}^2)(0.65\,\text{m})}{2(25\,\text{kg})(0.65\,\text{m})^2 + (60\,\text{kg})(0.45\,\text{m})^2}} = \boxed{4.38\,\text{rad/s}}$$

***121 ••**

Picture the Problem Let the smaller block have the dimensions shown in the diagram. Then the length, height, and width of the larger block are $S\ell$, Sh, and Sw, respectively. Let the numeral 1 denote the smaller block and the numeral 2 the larger block and express the ratios of the surface areas, masses, and moments of inertia of the two blocks.



(*a*) Express the ratio of the surface areas of the two blocks:

$$\frac{A_2}{A_1} = \frac{2(Sw)(S\ell) + 2(S\ell)(Sh) + 2(Sw)(Sh)}{2w\ell + 2\ell h + 2wh} = \frac{S^2(2w\ell + 2\ell h + 2wh)}{2w\ell + 2\ell h + 2wh} = \boxed{S^2}$$

(*b*) Express the ratio of the masses of the two blocks:

$$\frac{M_2}{M_1}=\frac{\rho V_2}{\rho V_1}=\frac{V_2}{V_1}=\frac{(Sw)(S\ell)(Sh)}{w\ell h}$$

$$=\frac{S^3(w\ell h)}{w\ell h}=\boxed{S^3}$$

(*c*) Express the ratio of the moments of inertia, about the axis shown in the diagram, of the two blocks:

$$\frac{I_2}{I_1}=\frac{\frac{1}{12}M_2\left[(S\ell)^2+(Sh)^2\right]}{\frac{1}{12}M_1\left[\ell^2+h^2\right]}$$

$$=\frac{M_2}{M_1}\frac{S^2\left[\ell^2+h^2\right]}{\left[\ell^2+h^2\right]}=\left(\frac{M_2}{M_1}\right)\left(S^2\right)$$

In part (*b*) we showed that:

$$\frac{M_2}{M_1}=S^3$$

Substitute to obtain:

$$\frac{I_2}{I_1}=\left(S^3\right)\left(S^2\right)=\boxed{S^5}$$

122 ••

Picture the Problem We can derive the perpendicular-axis theorem for planar objects by following the step-by-step procedure outlined in the problem.

(*a*) and (*b*)

$$I_z=\int r^2dm=\int\left(x^2+y^2\right)dm$$

$$=\int x^2dm+\int y^2dm$$

$$=\boxed{I_x+I_y}$$

(*c*) Let the *z* axis be the axis of rotation of the disk. By symmetry:

$$I_x=I_y$$

Express I_z in terms of I_x:

$$I_z=2I_x$$

Letting *M* represent the mass of the disk, solve for I_x:

$$I_x=\tfrac{1}{2}I_z=\tfrac{1}{2}\left(\tfrac{1}{2}MR^2\right)=\boxed{\tfrac{1}{4}MR^2}$$

123 ••

Picture the Problem Let the zero of gravitational potential energy be at the center of the disk when it is directly below the pivot. The initial gravitational potential energy of the disk is transformed into rotational kinetic energy when its center of mass is directly below the pivot. We can use Newton's 2nd law to relate the force exerted by the pivot to the weight of the disk and the centripetal force acting on it at its lowest point.

(*a*) Use the conservation of mechanical energy to relate the initial potential energy of the disk to its kinetic energy when its center of mass is directly below the pivot:

$$\Delta K + \Delta U = 0$$

or, because $K_i = U_f = 0$,

$$K_{f,rot} - U_i = 0$$

Substitute for $K_{f,rot}$ and U_i :

$$\tfrac{1}{2} I\omega^2 - Mgr = 0 \qquad (1)$$

Use the parallel-axis theorem to relate the moment of inertia of the disk about the pivot to its moment of inertia with respect to an axis through its center of mass:

$$I = I_{cm} + Mh^2$$

or

$$I = \tfrac{1}{2} Mr^2 + Mr^2 = \tfrac{3}{2} Mr^2$$

Solve equation (1) for ω and substitute for I to obtain:

$$\omega = \boxed{\sqrt{\frac{4g}{3r}}}$$

(*b*) Letting F represent the force exerted by the pivot, use Newton's 2nd law to express the net force acting on the swinging disk as it passes through its lowest point:

$$F_{net} = F - Mg = Mr\omega^2$$

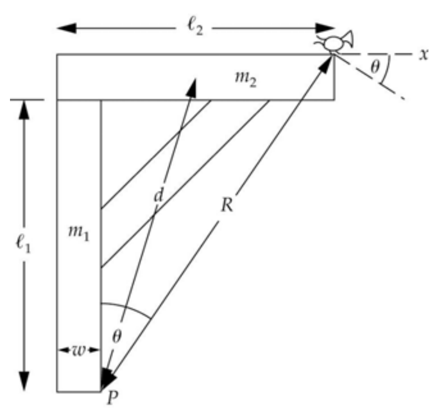
Solve for F and simplify to obtain:

$$F = Mg + Mr\omega^2 = Mg + Mr\frac{4g}{3r}$$

$$= Mg + \tfrac{4}{3} Mg = \boxed{\tfrac{7}{3} Mg}$$

124 ••

Picture the Problem The diagram shows a vertical cross-piece. Because we'll need to take moments about the point of rotation (point *P*), we'll need to use the parallel-axis theorem to find the moments of inertia of the two parts of this composite structure. Let the numeral 1 denote the vertical member and the numeral 2 the horizontal member. We can apply Newton's 2nd law in rotational form to the structure to express its angular acceleration in terms of the net torque causing it to fall and its moment of inertia with respect to point *P*.



(*a*) Taking clockwise rotation to be positive (this is the direction the structure is going to rotate), apply $\sum \tau = I_P \alpha$:

$$m_2 g\left(\frac{\ell_2}{2}\right) - m_1 g\left(\frac{w}{2}\right) = I_P \alpha$$

Solve for α to obtain:

$$\alpha = \frac{m_2 g \ell_2 - m_1 g w}{2I_P}$$

or

$$\alpha = \frac{g(m_2 \ell_2 - m_1 w)}{2(I_{1P} + I_{2P})} \qquad (1)$$

Convert $\ell_1, \ell_2,$ and w to SI units:

$$\ell_1 = 12\,\text{ft} \times \frac{1\,\text{m}}{3.281\,\text{ft}} = 3.66\,\text{m},$$

$$\ell_2 = 6\,\text{ft} \times \frac{1\,\text{m}}{3.281\,\text{ft}} = 1.83\,\text{m}, \text{ and}$$

$$w = 2\,\text{ft} \times \frac{1\,\text{m}}{3.281\,\text{ft}} = 0.610\,\text{m}$$

Using Table 9-1 and the parallel-axis theorem, express the moment of inertia of the vertical member about an axis through point *P*:

$$I_{1P} = \tfrac{1}{3} m_1 \ell_1^2 + m_1 \left(\frac{w}{2}\right)^2 = m_1\left(\tfrac{1}{3}\ell_1^2 + \tfrac{1}{4} w^2\right)$$

Substitute numerical values and evaluate I_{1P}:

$$I_{1P} = (350\,\text{kg})\left[\tfrac{1}{3}(3.66\,\text{m})^2 + \tfrac{1}{4}(0.610\,\text{m})^2\right] = 1.60 \times 10^3\,\text{kg}\cdot\text{m}^2$$

Using the parallel-axis theorem, express the moment of inertia of the horizontal member about an axis through point *P*:

$$I_{2P} = I_{2,\text{cm}} + m_2 d^2 \qquad (2)$$

where

$$d^2 = \left(\ell_1 + \tfrac{1}{2} w\right)^2 + \left(\tfrac{1}{2}\ell_2 - w\right)^2$$

Solve for *d*:

$$d = \sqrt{\left(\ell_1 + \tfrac{1}{2} w\right)^2 + \left(\tfrac{1}{2}\ell_2 - w\right)^2}$$

Substitute numerical values and evaluate *d*:

$$d = \sqrt{\left[3.66\,\text{m} + \tfrac{1}{2}(0.610\,\text{m})\right]^2 + \left[\tfrac{1}{2}(1.83\,\text{m}) - 0.610\,\text{m}\right]^2} = 3.86\,\text{m}$$

From Table 9-1 we have:

$$I_{2,\text{cm}} = \tfrac{1}{12} m_2 \ell_2^2$$

Substitute in equation (2) to obtain:

$$I_{2P} = \tfrac{1}{12} m_2 \ell_2^2 + m_2 d^2 = m_2\left(\tfrac{1}{12}\ell_2^2 + d^2\right)$$

Evaluate I_{2P}:

$$I_{2P} = (175\,\text{kg})\left[\tfrac{1}{12}(1.83\,\text{m})^2 + (3.86\,\text{m})^2\right] = 2.66\times10^3\ \text{kg}\cdot\text{m}^2$$

Substitute in equation (1) and evaluate α:

$$\alpha = \frac{(9.81\,\text{m/s}^2)[(175\,\text{kg})(1.83\,\text{m}) - (350\,\text{kg})(0.61\,\text{m})]}{2(1.60 + 2.66)\times10^3\ \text{kg}\cdot\text{m}^2} = \boxed{0.123\,\text{rad/s}^2}$$

(*b*) Express the magnitude of the acceleration of the sparrow:

$a = \alpha R$

where R is the distance of the sparrow from the point of rotation and

$$R^2 = (\ell_1 + w)^2 + (\ell_2 - w)^2$$

Solve for R:

$$R = \sqrt{(\ell_1 + w)^2 + (\ell_2 - w)^2}$$

Substitute numerical values and evaluate R:

$$R = \sqrt{(3.66\,\text{m} + 0.610\,\text{m})^2 + (1.83\,\text{m} - 0.610\,\text{m})^2} = 4.44\,\text{m}$$

Substitute numerical values and evaluate a:

$$a = (0.123\,\text{rad/s}^2)(4.44\,\text{m}) = \boxed{0.546\,\text{m/s}^2}$$

(*c*) Refer to the diagram to express a_x in terms of a:

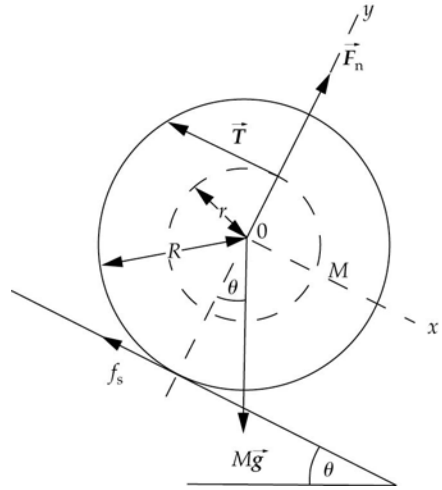
$$a_x = a\cos\theta = a\frac{\ell_1 + w}{R}$$

Substitute numerical values and evaluate a_x:

$$a_x = (0.546\,\text{m/s}^2)\frac{3.66\,\text{m} + 0.61\,\text{m}}{4.44\,\text{m}} = \boxed{0.525\,\text{m/s}^2}$$

125 ••

Picture the Problem Let the zero of gravitational potential energy be at the bottom of the incline. The initial potential energy of the spool is transformed into rotational and translational kinetic energy when the spool reaches the bottom of the incline. We can apply the conservation of mechanical energy to find an expression for its speed at that location. The force diagram shows the forces acting on the spool when there is enough friction to keep it from slipping. We'll use Newton's 2nd law in both translational and rotational form to derive an expression for the static friction force.



(*a*) In the absence of friction, the forces acting on the spool will be its weight, the normal force exerted by the incline, and the tension in the string. A component of its weight will cause the spool to accelerate down the incline and the tension in the string will exert a torque that will cause counterclockwise rotation of the spool.

The spool will move down the plane at constant acceleration, spinning in a counterclockwise direction as string unwinds.

Use the conservation of mechanical energy to relate the speed of the center of mass of the spool at the bottom of the slope to its initial potential energy:

$$\Delta K + \Delta U = 0$$

or, because $K_i = U_f = 0$,

$$K_{f,trans} + K_{f,rot} - U_i = 0.$$

Substitute for $K_{f,trans}$, $K_{f,rot}$ and U_i:

$$\tfrac{1}{2}Mv^2 + \tfrac{1}{2}I\omega^2 - MgD\sin\theta = 0 \quad (1)$$

Substitute for ω and solve for v to obtain:

$$\tfrac{1}{2}Mv^2 + \tfrac{1}{2}I\frac{v^2}{r^2} - MgD\sin\theta = 0$$

and

$$\boxed{v = \sqrt{\frac{2MgD\sin\theta}{M + \frac{I}{r^2}}}}$$

(*b*) Apply Newton's 2nd law to the spool:

$$\sum F_x = Mg\sin\theta - T - f_s = 0$$
$$\sum \tau_0 = Tr - f_s R = 0$$

Eliminate T between these equations to obtain:

$$f_s = \boxed{\frac{Mg\sin\theta}{1+\frac{R}{r}}}$$, up the incline.

126 ••

Picture the Problem While the angular acceleration of the rod is the same at each point along its length, the linear acceleration and, hence, the force exerted on each coin by the rod, varies along its length. We can relate this force the linear acceleration of the rod through Newton's 2nd law and the angular acceleration of the rod.

Letting x be the distance from the pivot, use Newton's 2nd law to express the force F acting on a coin:

$$F_{net} = mg - F(x) = ma(x)$$
or
$$F(x) = m(g - a(x)) \quad (1)$$

Use Newton's 2nd law to relate the angular acceleration of the system to the net torque acting on it:

$$\alpha = \frac{\tau_{net}}{I} = \frac{Mg\frac{L}{2}}{\frac{1}{3}ML^2} = \frac{3g}{2L}$$

Relate $a(x)$ and α:

$$a(x) = x\alpha = x\frac{3g}{2(1.5\,\text{m})} = gx$$

Substitute in equation (1) to obtain:

$$F(x) = m(g - gx) = mg(1 - x)$$

Evaluate $F(0.25\text{ m})$:

$$F(0.25\,\text{m}) = mg(1 - 0.25\,\text{m}) = \boxed{0.75mg}$$

Evaluate $F(0.5\text{ m})$:

$$F(0.5\,\text{m}) = mg(1 - 0.5\,\text{m}) = \boxed{0.5mg}$$

Evaluate $F(0.75\text{ m})$:

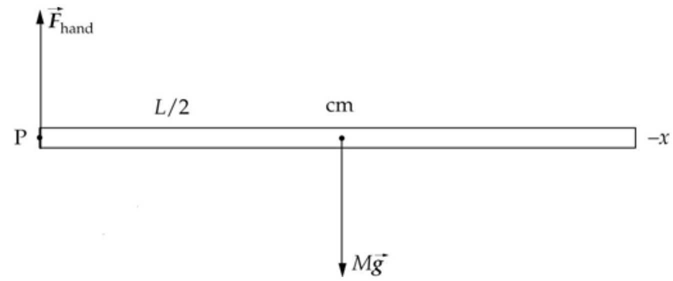
$$F(0.75\,\text{m}) = mg(1 - 0.75\,\text{m}) = \boxed{0.25mg}$$

Evaluate $F(1\text{ m})$:

$$F(1\,\text{m}) = F(1.25\,\text{m}) = F(1.5\,\text{m}) = \boxed{0}$$

***127** ••

Picture the Problem The diagram shows the force the hand supporting the meterstick exerts at the pivot point and the force the earth exerts on the meterstick acting at the center of mass. We can relate the angular acceleration to the acceleration of the end of the meterstick using $a = L\alpha$ and use Newton's 2nd law in rotational form to relate α to the moment of inertia of the meterstick.



(*a*) Relate the acceleration of the far end of the meterstick to the angular acceleration of the meterstick:

$$a = L\alpha \qquad (1)$$

Apply $\sum \tau_P = I_P\alpha$ to the meterstick:

$$Mg\left(\frac{L}{2}\right) = I_P\alpha$$

Solve for α:

$$\alpha = \frac{MgL}{2I_P}$$

From Table 9-1, for a rod pivoted at one end, we have:

$$I_P = \frac{1}{3}ML^2$$

Substitute to obtain:

$$\alpha = \frac{3MgL}{2ML^2} = \frac{3g}{2L}$$

Substitute in equation (1) to obtain:

$$a = \frac{3g}{2}$$

Substitute numerical values and evaluate *a*:

$$a = \frac{3(9.81\,\text{m/s}^2)}{2} = \boxed{14.7\,\text{m/s}^2}$$

(*b*) Express the acceleration of a point on the meterstick a distance *x* from the pivot point:

$$a = \alpha x = \frac{3g}{2L}x$$

Express the condition that the meterstick leaves the penny behind:

$$a > g$$

Substitute to obtain:

$$\frac{3g}{2L}x > g$$

Solve for and evaluate *x*:

$$x > \frac{2L}{3} = \frac{2(1\,\text{m})}{3} = \boxed{66.7\,\text{cm}}$$

128 ••

Picture the Problem Let m represent the 0.2-kg mass, M the 0.8-kg mass of the cylinder, L the 1.8-m length, and $x + \Delta x$ the distance from the center of the objects whose mass is m. We can use Newton's 2nd law to relate the radial forces on the masses to the spring's stiffness constant and use the work-energy theorem to find the work done as the system accelerates to its final angular speed.

(*a*) Express the net inward force acting on each of the 0.2-kg masses:

$$\sum F_{\text{radial}} = k\Delta x = m(x+\Delta x)\omega^2$$

Solve for k:

$$k = \frac{m(x+\Delta x)\omega^2}{\Delta x}$$

Substitute numerical values and evaluate k:

$$k = \frac{(0.2\,\text{kg})(0.8\,\text{m})(24\,\text{rad/s})^2}{0.4\,\text{m}} = \boxed{230\,\text{N/m}}$$

(*b*) Using the work-energy theorem, relate the work done to the change in energy of the system:

$$W = K_{\text{rot}} + \Delta U_{\text{spring}} = \tfrac{1}{2}I\omega^2 + \tfrac{1}{2}k(\Delta x)^2 \qquad (1)$$

Express I as the sum of the moments of inertia of the cylinder and the masses:

$$I = I_M + I_{2m} = \tfrac{1}{2}Mr^2 + \tfrac{1}{12}ML^2 + 2I_m$$

From Table 9-1 we have, for a solid cylinder about a diameter through its center:

$$I = \tfrac{1}{4}mr^2 + \tfrac{1}{12}mL^2$$

where L is the length of the cylinder.

For a disk (thin cylinder), L is small and:

$$I = \tfrac{1}{4}mr^2$$

Apply the parallel-axis theorem to obtain:

$$I_m = \tfrac{1}{4}mr^2 + mx^2$$

Substitute to obtain:

$$I = \tfrac{1}{2}Mr^2 + \tfrac{1}{12}ML^2 + 2\left(\tfrac{1}{4}mr^2 + mx^2\right) = \tfrac{1}{2}Mr^2 + \tfrac{1}{12}ML^2 + 2m\left(\tfrac{1}{4}r^2 + x^2\right)$$

Substitute numerical values and evaluate I:

$$I = \tfrac{1}{2}(0.8\,\text{kg})(0.2\,\text{m})^2 + \tfrac{1}{12}(0.8\,\text{kg})(1.8\,\text{m})^2 + 2(0.2\,\text{kg})\left[\tfrac{1}{4}(0.2\,\text{m})^2 + (0.8\,\text{m})^2\right]$$
$$= 0.492\,\text{N}\cdot\text{m}^2$$

Substitute in equation (1) to obtain:

$$W = \tfrac{1}{2}(0.492\,\text{N}\cdot\text{m}^2)(24\,\text{rad/s})^2 + \tfrac{1}{2}(230\,\text{N/m})(0.4\,\text{m})^2 = \boxed{160\,\text{J}}$$

129 ••

Picture the Problem Let m represent the 0.2-kg mass, M the 0.8-kg mass of the cylinder, L the 1.8-m length, and $x + \Delta x$ the distance from the center of the objects whose mass is m. We can use Newton's 2nd law to relate the radial forces on the masses to the spring's stiffness constant and use the work-energy theorem to find the work done as the system accelerates to its final angular speed.

Using the work-energy theorem, relate the work done to the change in energy of the system:

$$W = K_{\text{rot}} + \Delta U_{\text{spring}} = \tfrac{1}{2}I\omega^2 + \tfrac{1}{2}k(\Delta x)^2 \qquad (1)$$

Express I as the sum of the moments of inertia of the cylinder and the masses:

$$I = I_M + I_{2m} = \tfrac{1}{2}Mr^2 + \tfrac{1}{12}ML^2 + 2I_m$$

From Table 9-1 we have, for a solid cylinder about a diameter through its center:

$$I = \tfrac{1}{4}mr^2 + \tfrac{1}{12}mL^2$$

where L is the length of the cylinder.

For a disk (thin cylinder), L is small and:

$$I = \tfrac{1}{4}mr^2$$

Apply the parallel-axis theorem to obtain:

$$I_m = \tfrac{1}{4}mr^2 + mx^2$$

Substitute to obtain:

$$I = \tfrac{1}{2}Mr^2 + \tfrac{1}{12}ML^2 + 2\left(\tfrac{1}{4}mr^2 + mx^2\right)$$
$$= \tfrac{1}{2}Mr^2 + \tfrac{1}{12}ML^2 + 2m\left(\tfrac{1}{4}r^2 + x^2\right)$$

Substitute numerical values and evaluate I:

$$I = \tfrac{1}{2}(0.8\,\text{kg})(0.2\,\text{m})^2 + \tfrac{1}{12}(0.8\,\text{kg})(1.8\,\text{m})^2 + 2(0.2\,\text{kg})\left[\tfrac{1}{4}(0.2\,\text{m})^2 + (0.8\,\text{m})^2\right]$$
$$= 0.492\,\text{N}\cdot\text{m}^2$$

Express the net inward force acting on each of the 0.2-kg masses:

$$\sum F_{\text{radial}} = k\Delta x = m(x+\Delta x)\omega^2$$

Solve for ω:

$$\omega = \sqrt{\frac{k\Delta x}{m(x+\Delta x)}}$$

Substitute numerical values and evaluate ω:

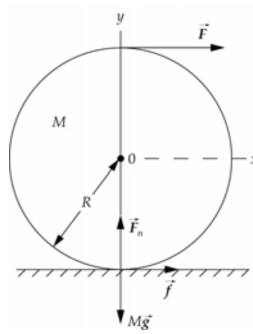
$$\omega = \sqrt{\frac{(60\,\text{N/m})(0.4\,\text{m})}{(0.2\,\text{kg})(0.8\,\text{m})}} = 12.2\,\text{rad/s}$$

Substitute numerical values in equation (1) to obtain:

$$W = \tfrac{1}{2}\left(0.492\,\text{N}\cdot\text{m}^2\right)(12.2\,\text{rad/s})^2 + \tfrac{1}{2}(60\,\text{N/m})(0.4\,\text{m})^2 = \boxed{41.4\,\text{J}}$$

130 ••

Picture the Problem The force diagram shows the forces acting on the cylinder. Because F causes the cylinder to rotate clockwise, f, which opposes this motion, is to the right. We can use Newton's 2nd law in both translational and rotational forms to relate the linear and angular accelerations to the forces acting on the cylinder.



(*a*) Use Newton's 2nd law to relate the angular acceleration of the center of mass of the cylinder to F:

$$\alpha = \frac{\tau_{\text{net}}}{I} = \frac{FR}{\frac{1}{2}MR^2} = \frac{2F}{MR}$$

Use Newton's 2nd law to relate the acceleration of the center of mass of the cylinder to F:

$$a_{\text{cm}} = \frac{F_{\text{net}}}{M} = \frac{F}{M}$$

Express the rolling-without-slipping condition to the accelerations:

$$\alpha' = \frac{a_{\text{cm}}}{R} = \frac{F}{MR} = \boxed{2\alpha}$$

(*b*) Take the point of contact with the floor as the "pivot" point, express the net torque about that point, and solve for α:

$$\tau_{\text{net}} = 2FR = I\alpha$$

and

$$\alpha = \frac{2FR}{I}$$

Express the moment of inertia of the cylinder with respect to the pivot point:

$$I = \tfrac{1}{2}MR^2 + MR^2 = \tfrac{3}{2}MR^2$$

Substitute to obtain:

$$\alpha = \frac{2FR}{\tfrac{3}{2}MR^2} = \frac{4F}{3MR}$$

Express the linear acceleration of the cylinder:

$$a_{cm} = R\alpha = \boxed{\frac{4F}{3M}}$$

Apply Newton's 2nd law to the forces acting on the cylinder:

$$\sum F_x = F + f = Ma_{cm}$$

Solve for f:

$$f = Ma_{cm} - F = \frac{4F}{3} - F$$
$$= \boxed{\tfrac{1}{3}F \text{ in the positive } x \text{ direction.}}$$

131 ••

Picture the Problem As the load falls, mechanical energy is conserved. As in Example 9-7, choose the initial potential energy to be zero. Apply conservation of mechanical energy to obtain an expression for the speed of the bucket as a function of its position and use the given expression for t to determine the time required for the bucket to travel a distance y.

Apply conservation of mechanical energy:

$$U_f + K_f = U_i + K_i = 0 + 0 = 0 \quad (1)$$

Express the total potential energy when the bucket has fallen a distance y:

$$U_f = U_{bf} + U_{cf} + U_{wf}$$
$$= -mgy - m_c'g\left(\frac{y}{2}\right)$$

where m_c' is the mass of the hanging part of the cable.

Assume the cable is uniform and express m_c' in terms of m_c, y, and L:

$$\frac{m_c'}{y} = \frac{m_c}{L} \text{ or } m_c' = \frac{m_c}{L}y$$

Substitute to obtain:

$$U_f = -mgy - \frac{m_c g y^2}{2L}$$

Noting that bucket, cable, and rim of the winch have the same speed v, express the total kinetic energy when the bucket is falling with speed v:

$$K_f = K_{bf} + K_{cf} + K_{wf} = \tfrac{1}{2}mv^2 + \tfrac{1}{2}m_c v^2 + \tfrac{1}{2}I\omega_f^2 = \tfrac{1}{2}mv^2 + \tfrac{1}{2}m_c v^2 + \tfrac{1}{2}\left(\tfrac{1}{2}MR^2\right)\frac{v^2}{R^2} = \tfrac{1}{2}mv^2 + \tfrac{1}{2}m_c v^2 + \tfrac{1}{4}Mv^2$$

Substitute in equation (1) to obtain:

$$-mgy - \frac{m_c gy^2}{2L} + \tfrac{1}{2}mv^2 + \tfrac{1}{2}m_c v^2 + \tfrac{1}{4}Mv^2 = 0$$

Solve for v:

$$v = \sqrt{\frac{4mgy + \dfrac{2m_c gy^2}{L}}{M + 2m + 2m_c}}$$

A spreadsheet solution is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
D9	0	y_0
D10	D9+$B$8	$y + \Delta y$
E9	0	v_0
E10	((4*$B$3*$B$7*D10+2*$B$7*D10^2/(2*$B$5))/ ($B$1+2*$B$3+2*$B$4))^0.5	$\sqrt{\frac{4mgy + \frac{2m_c gy^2}{L}}{M + 2m + 2m_c}}$

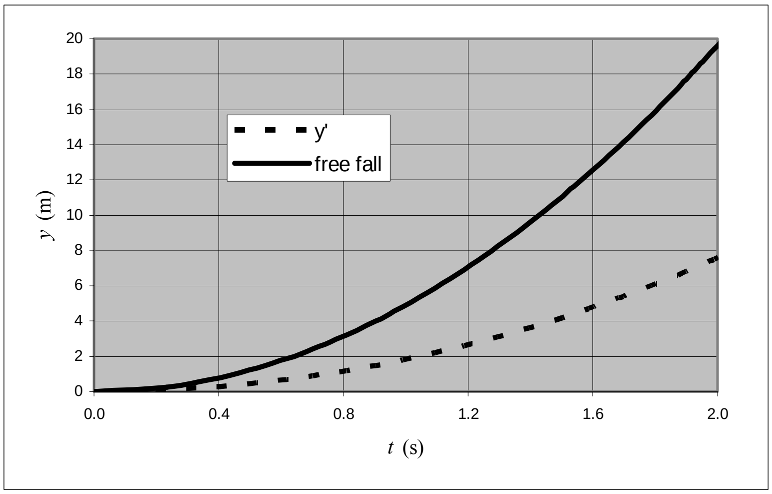
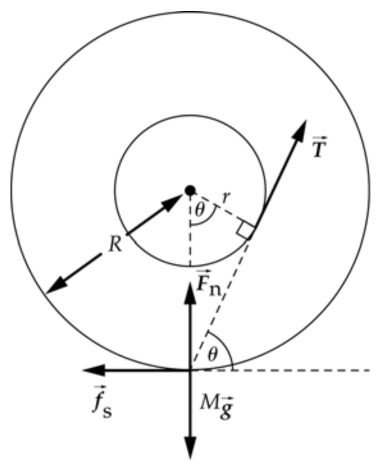
The solid line on the graph shown below shows the position y of the bucket when it is in free fall and the dashed line shows y under the conditions modeled in this problem.



132 ••

Picture the Problem The pictorial representation shows the forces acting on the cylinder when it is stationary. First, we note that if the tension is small, then there can be no slipping, and the system must roll. Now consider the point of contact of the cylinder with the surface as the "pivot" point. If τ about that point is zero, the system will not roll. This will occur if the line of action of the tension passes through the pivot point.

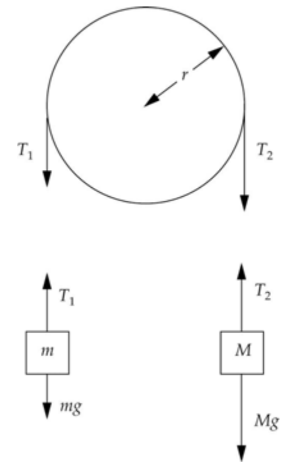


From the diagram we see that:

$$\theta = \boxed{\cos^{-1}\left(\frac{r}{R}\right)}$$

***133** ••

Picture the Problem Free-body diagrams for the pulley and the two blocks are shown to the right. Choose a coordinate system in which the direction of motion of the block whose mass is M (downward) is the positive y direction. We can use the given relationship $T'_{\text{max}} = Te^{\mu_s \Delta\theta}$ to relate the tensions in the rope on either side of the pulley and apply Newton's 2nd law in both rotational form (to the pulley) and translational form (to the blocks) to obtain a system of equations that we can solve simultaneously for a, T_1, T_2, and M.



(*a*) Use $T'_{\text{max}} = Te^{\mu_s \Delta\theta}$ to evaluate the maximum tension required to prevent the rope from slipping on the pulley:

$$T'_{\text{max}} = (10\,\text{N})e^{(0.3)\pi} = \boxed{25.7\,\text{N}}$$

(*c*) Given that the angle of wrap is π radians, express T_2 in terms of T_1:

$$T_2 = T_1 e^{0.3\pi} = 2.57T_1 \qquad (1)$$

Because the rope doesn't slip, we can relate the angular acceleration, α, of the pulley to the acceleration, a, of the hanging masses by:

$$\alpha = \frac{a}{r}$$

Apply $\sum F_y = ma_y$ to the two blocks to obtain:

$$T_1 - mg = ma \qquad (2)$$

and

$$Mg - T_2 = Ma \qquad (3)$$

Apply $\sum \tau = I\alpha$ to the pulley to obtain:

$$(T_2 - T_1)r = I\frac{a}{r} \qquad (4)$$

Substitute for T_2 from equation (1) in equation (4) to obtain:

$$(2.57T_1 - T_1)r = I\frac{a}{r}$$

Solve for T_1 and substitute numerical values to obtain:

$$T_1 = \frac{I}{1.57r^2}a = \frac{0.35\,\text{kg}\cdot\text{m}^2}{1.57(0.15\,\text{m})^2}a \qquad (5)$$
$$= (9.91\,\text{kg})a$$

Substitute in equation (2) to obtain:

$$(9.91\,\text{kg})a - mg = ma$$

Solve for and evaluate a:

$$a = \frac{mg}{9.91\,\text{kg} - m} = \frac{g}{\frac{9.91\,\text{kg}}{m} - 1}$$

$$= \frac{9.81\,\text{m/s}^2}{\frac{9.91\,\text{kg}}{1\,\text{kg}} - 1} = \boxed{1.10\,\text{m/s}^2}$$

(b) Solve equation (3) for M:

$$M = \frac{T_2}{g - a}$$

Substitute in equation (5) to find T_1:

$$T_1 = (9.91\,\text{kg})(1.10\,\text{m/s}^2) = 10.9\,\text{N}$$

Substitute in equation (1) to find T_2:

$$T_2 = (2.57)(10.9\,\text{N}) = 28.0\,\text{N}$$

Evaluate M:

$$M = \frac{28.0\,\text{N}}{9.81\,\text{m/s}^2 - 1.10\,\text{m/s}^2} = \boxed{3.21\,\text{kg}}$$

134 •••

Picture the Problem When the tension is horizontal, the cylinder will roll forward and the friction force will be in the direction of $\vec{T}$. We can use Newton's 2nd law to obtain equations that we can solve simultaneously for a and f.

(a) Apply Newton's 2nd law to the cylinder:

$$\sum F_x = T + f = ma \qquad (1)$$

and

$$\sum \tau = Tr - fR = I\alpha \qquad (2)$$

Substitute for I and α in equation (2) to obtain:

$$Tr - fR = \tfrac{1}{2} mR^2 \frac{a}{R} = \tfrac{1}{2} mRa \qquad (3)$$

Solve equation (3) for f:

$$f = \frac{Tr}{R} - \tfrac{1}{2} ma \qquad (4)$$

Substitute equation (4) in equation (1) and solve for a:

$$a = \frac{2T}{3m}\left(1 + \frac{r}{R}\right) \qquad (5)$$

Substitute equation (5) in equation (4) to obtain:

$$f = \boxed{\frac{T}{3}\left(\frac{2r}{R} - 1\right)}$$

(b) Equation (4) gives the acceleration of the center of mass:

$$a = \boxed{\frac{2T}{3m}\left(1 + \frac{r}{R}\right)}$$

(*c*) Express the condition that $a > \frac{T}{m}$:

$$\frac{2T}{3m}\left(1+\frac{r}{R}\right) > \frac{T}{m} \Rightarrow \frac{2}{3}\left(1+\frac{r}{R}\right) > 1$$

or

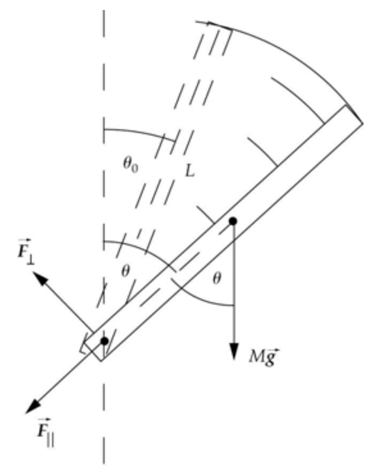
$$r > \boxed{\tfrac{1}{2}R}$$

(*d*) If $r > \frac{1}{2}R$:

$$\boxed{f > 0\text{, i.e., in the direction of } \vec{\boldsymbol{T}}.}$$

135 •••

Picture the Problem The system is shown in the drawing in two positions, with angles θ_0 and θ with the vertical. The drawing also shows all the forces that act on the stick. These forces result in a rotation of the stick—and its center of mass—about the pivot, and a tangential acceleration of the center of mass. We'll apply the conservation of mechanical energy and Newton's 2nd law to relate the radial and tangential forces acting on the stick.



Use the conservation of mechanical energy to relate the kinetic energy of the stick when it makes an angle θ with the vertical and its initial potential energy:

$$K_\text{f} - K_\text{i} + U_\text{f} - U_\text{i} = 0$$

or, because $K_\text{f} = 0$,

$$-\tfrac{1}{2}I\omega^2 + Mg\frac{L}{2}\cos\theta - Mg\frac{L}{2}\cos\theta_0 = 0$$

Substitute for I and solve for ω^2:

$$\omega^2 = \frac{3g}{L}\left(\cos\theta - \cos\theta_0\right)$$

Express the centripetal force acting on the center of mass:

$$F_\text{c} = M\frac{L}{2}\omega^2$$
$$= M\frac{L}{2}\frac{3g}{L}\left(\cos\theta - \cos\theta_0\right)$$
$$= \frac{3Mg}{2}\left(\cos\theta - \cos\theta_0\right)$$

Express the radial component of $M\vec{\boldsymbol{g}}$:

$$(Mg)_\text{radial} = Mg\cos\theta$$

Express the total radial force at the hinge:

$$F_{||} = F_\text{c} + (Mg)_\text{radial}$$

$$= \frac{3Mg}{2}\left(\cos\theta - \cos\theta_0\right) + Mg\cos\theta$$

$$= \boxed{\tfrac{1}{2}Mg\left(5\cos\theta - 3\cos\theta_0\right)}$$

Relate the tangential acceleration of the center of mass to its angular acceleration:

$$a_\perp = \tfrac{1}{2}L\alpha$$

Use Newton's 2nd law to relate the angular acceleration of the stick to the net torque acting on it:

$$\alpha = \frac{\tau_{\text{net}}}{I} = \frac{Mg\frac{L}{2}\sin\theta}{\frac{1}{3}ML^2} = \frac{3g\sin\theta}{2L}$$

Express $a_\perp$ in terms of α:

$$a_\perp = \tfrac{1}{2}L\alpha = \tfrac{3}{4}g\sin\theta = g\sin\theta + F_\perp/M$$

Solve for $F_\perp$ to obtain:

$F_\perp = \boxed{-\tfrac{1}{4}Mg\sin\theta}$ where the minus sign indicates that the force is directed oppositely to the tangential component of $M\vec{\boldsymbol{g}}$.

Chapter 10
Conservation of Angular Momentum

Conceptual Problems

***1** •

(*a*) True. The cross product of the vectors $\vec{A}$ and $\vec{B}$ is defined to be $\vec{A}\times\vec{B} = AB\sin\phi\,\hat{n}$. If $\vec{A}$ and $\vec{B}$ are parallel, $\sin\phi = 0$.

(*b*) True. By definition, $\vec{\omega}$ is along the axis.

(*c*) True. The direction of a torque exerted by a force is determined by the definition of the cross product.

2 •

Determine the Concept The cross product of the vectors $\vec{A}$ and $\vec{B}$ is defined to be $\vec{A}\times\vec{B} = AB\sin\phi\,\hat{n}$. Hence, the cross product is a maximum when $\sin\phi = 1$. This condition is satisfied provided $\vec{A}$ and $\vec{B}$ are *perpendicular*. $\boxed{(c)\text{ is correct.}}$

3 •

Determine the Concept $\vec{L}$ and $\vec{p}$ are related according to $\vec{L} = \vec{r}\times\vec{p}$. From this definition of the cross product, $\vec{L}$ and $\vec{p}$ are perpendicular; i.e., the angle between them is 90°.

4 •

Determine the Concept $\vec{L}$ and $\vec{p}$ are related according to $\vec{L} = \vec{r}\times\vec{p}$. Because the motion is along a line that passes through point *P*, $r = 0$ and so is L. $\boxed{(b)\text{ is correct.}}$

***5** ••

Determine the Concept $\vec{L}$ and $\vec{p}$ are related according to $\vec{L} = \vec{r}\times\vec{p}$.

(*a*) Because $\vec{L}$ is directly proportional to $\vec{p}$:

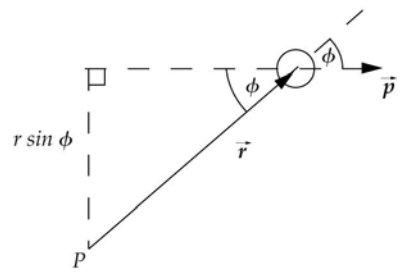
$$\boxed{\text{Doubling } \vec{p} \text{ doubles } \vec{L}.}$$

(*b*) Because $\vec{L}$ is directly proportional to $\vec{r}$:

$$\boxed{\text{Doubling } \vec{r} \text{ doubles } \vec{L}.}$$

6 ••

Determine the Concept The figure shows a particle moving with constant speed in a straight line (i.e., with constant velocity and constant linear momentum). The magnitude of L is given by $rp\sin\phi = mv(r\sin\phi)$.



Referring to the diagram, note that the distance $r\sin\phi$ from P to the line along which the particle is moving is constant. Hence, $mv(r\sin\phi)$ is constant and so $\boxed{\vec{L} \text{ is constant.}}$

7 •

False. The net torque acting on a rotating system equals the change in the system's angular momentum; i.e., $\tau_{\text{net}} = dL/dt$, where $L = I\omega$. Hence, if τ_{net} is zero, all we can say for sure is that the angular momentum (the product of I and ω) is constant. If I changes, so must ω.

***8 ••**

Determine the Concept Yes, you can. Imagine rotating the top half of your body with arms flat at sides through a (roughly) 90° angle. Because the net angular momentum of the system is 0, the bottom half of your body rotates in the opposite direction. Now extend your arms out and rotate the top half of your body back. Because the moment of inertia of the top half of your body is larger than it was previously, the angle which the bottom half of your body rotates through will be smaller, leading to a net rotation. You can repeat this process as necessary to rotate through any arbitrary angle.

9 •

Determine the Concept If L is constant, we know that the *net* torque acting on the system is zero. There may be multiple constant or time-dependent torques acting on the system as long as the net torque is zero. $\boxed{(e) \text{ is correct.}}$

10 ••

Determine the Concept No. In order to do work, a force must act over some distance. In each "inelastic collision" the force of static friction does not act through any distance.

11 ••

Determine the Concept It is easier to crawl radially outward. In fact, a radially inward force is required just to prevent you from sliding outward.

***12 ••**

Determine the Concept The pull that the student exerts on the block is at right angles to its motion and exerts no torque (recall that $\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{r}} \times \vec{\boldsymbol{F}}$ and $\tau = rF\sin\theta$). Therefore, we can conclude that the angular momentum of the block is conserved. The student does, however, do work in displacing the block in the direction of the radial force and so the block's energy increases. $\boxed{(b) \text{ is correct.}}$

***13 ••**

Determine the Concept The hardboiled egg is solid inside, so everything rotates with a uniform velocity. By contrast, it is difficult to get the viscous fluid inside a raw egg to start rotating; however, once it is rotating, stopping the shell will not stop the motion of the interior fluid, and the egg may start rotating again after momentarily stopping for this reason.

14 •

False. The relationship $\vec{\boldsymbol{\tau}} = d\vec{\boldsymbol{L}}/dt$ describes the motion of a gyroscope independently of whether it is spinning.

15 •

Picture the Problem We can divide the expression for the kinetic energy of the object by the expression for its angular momentum to obtain an expression for K as a function of I and L.

Express the rotational kinetic energy of the object:

$$K = \tfrac{1}{2} I\omega^2$$

Relate the angular momentum of the object to its moment of inertia and angular velocity:

$$L = I\omega$$

Divide the first of these equations by the second and solve for K to obtain:

$$K = \frac{L^2}{2I} \text{ and so } \boxed{(b) \text{ is correct.}}$$

16 •

Determine the Concept The purpose of the second smaller rotor is to prevent the body of the helicopter from rotating. If the rear rotor fails, the body of the helicopter will tend to rotate on the main axis due to angular momentum being conserved.

17 ••

Determine the Concept One can use a right-hand rule to determine the direction of the torque required to turn the angular momentum vector from east to south. Letting the fingers of your right hand point east, rotate your wrist until your fingers point south. Note that your thumb points downward. $\boxed{(b) \text{ is correct.}}$

18 ••

Determine the Concept In turning east, the man redirects the angular momentum vector from north to east by exerting a clockwise torque (viewed from above) on the gyroscope. As a consequence of this torque, the front end of the suitcase will dip downward. $\boxed{(d)\text{ is correct.}}$

19 ••

(a) The lifting of the nose of the plane rotates the angular momentum vector upward. It veers to the right in response to the torque associated with the lifting of the nose.

(b) The angular momentum vector is rotated to the right when the plane turns to the right. In turning to the right, the torque points down. The nose will move downward.

20 ••

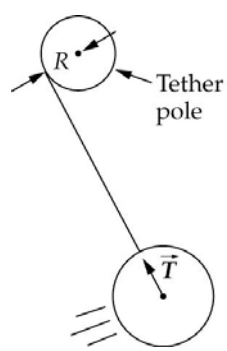
Determine the Concept If $\vec{L}$ points up and the car travels over a hill or through a valley, the force on the wheels on one side (or the other) will increase and car will tend to tip. If $\vec{L}$ points forward and car turns left or right, the front (or rear) of the car will tend to lift. These problems can be averted by having two identical flywheels that rotate on the same shaft in opposite directions.

21 ••

Determine the Concept The rotational kinetic energy of the woman-plus-stool system is given by $K_{\text{rot}} = \frac{1}{2}I\omega^2 = L^2/2I$. Because L is constant (angular momentum is conserved) and her moment of inertia is greater with her arms extended, $\boxed{(b)\text{ is correct.}}$

***22** ••

Determine the Concept Consider the overhead view of a tether pole and ball shown in the adjoining figure. The ball rotates counterclockwise. The torque about the center of the pole is clockwise and of magnitude RT, where R is the pole's radius and T is the tension. So L must decrease and $\boxed{(e)\text{ is correct.}}$



23 ••

Determine the Concept The center of mass of the rod-and-putty system moves in a straight line, and the system rotates about its center of mass.

24 •

(*a*) True. The net external torque acting a system equals the rate of change of the angular momentum of the system; i.e., $\sum_i \vec{\boldsymbol{\tau}}_{\text{i,ext}} = \frac{d\vec{\boldsymbol{L}}}{dt}$.

(*b*) False. If the net torque on a body is zero, its angular momentum is *constant* but not necessarily zero.

Estimation and Approximation

***25** ••

Picture the Problem Because we have no information regarding the mass of the skater, we'll assume that her body mass (not including her arms) is 50 kg and that each arm has a mass of 4 kg. Let's also assume that her arms are 1 m long and that her body is cylindrical with a radius of 20 cm. Because the net external torque acting on her is zero, her angular momentum will remain constant during her pirouette.

Express the conservation of her angular momentum during her pirouette:

$$L_{\text{i}} = L_{\text{f}}$$

or

$$I_{\text{arms out}}\omega_{\text{arms out}} = I_{\text{arms in}}\omega_{\text{arms in}} \qquad (1)$$

Express her total moment of inertia with her arms out:

$$I_{\text{arms out}} = I_{\text{body}} + I_{\text{arms}}$$

Treating her body as though it is cylindrical, calculate its moment of inertia of her body, minus her arms:

$$I_{\text{body}} = \tfrac{1}{2}mr^2 = \tfrac{1}{2}(50\,\text{kg})(0.2\,\text{m})^2 = 1.00\,\text{kg}\cdot\text{m}^2$$

Modeling her arms as though they are rods, calculate their moment of inertia when she has them out:

$$I_{\text{arms}} = 2\left[\tfrac{1}{3}(4\,\text{kg})(1\,\text{m})^2\right] = 2.67\,\text{kg}\cdot\text{m}^2$$

Substitute to determine her total moment of inertia with her arms out:

$$I_{\text{arms out}} = 1.00\,\text{kg}\cdot\text{m}^2 + 2.67\,\text{kg}\cdot\text{m}^2 = 3.67\,\text{kg}\cdot\text{m}^2$$

Express her total moment of inertia with her arms in:

$$I_{\text{arms}\,in} = I_{\text{body}} + I_{\text{arms}} = 1.00\,\text{kg}\cdot\text{m}^2 + 2\left[(4\,\text{kg})(0.2\,\text{m})^2\right] = 1.32\,\text{kg}\cdot\text{m}^2$$

Solve equation (1) for $\omega_{\text{arms in}}$ and substitute to obtain:

$$\omega_{\text{arms in}} = \frac{I_{\text{arms out}}}{I_{\text{arms in}}}\omega_{\text{arms out}} = \frac{3.67\,\text{kg}\cdot\text{m}^2}{1.32\,\text{kg}\cdot\text{m}^2}(1.5\,\text{rev/s}) = \boxed{4.17\,\text{rev/s}}$$

26 ••

Picture the Problem We can express the period of the earth's rotation in terms of its angular velocity of rotation and relate its angular velocity to its angular momentum and moment of inertia with respect to an axis through its center. We can differentiate this expression with respect to *I* and then use differentials to approximate the changes in *I* and *T*.

Express the period of the earth's rotation in terms of its angular velocity of rotation:

$$T = \frac{2\pi}{\omega}$$

Relate the earth's angular velocity of rotation to its angular momentum and moment of inertia:

$$\omega = \frac{L}{I}$$

Substitute to obtain:

$$T = \frac{2\pi I}{L}$$

Find dT/dI:

$$\frac{dT}{dI} = \frac{2\pi}{L} = \frac{T}{I}$$

Solve for dT/T and approximate ΔT:

$$\frac{dT}{T} = \frac{dI}{I} \text{ or } \Delta T \approx \frac{\Delta I}{I}T$$

Substitute for ΔI and I to obtain:

$$\Delta T \approx \frac{\frac{2}{3}mr^2}{\frac{2}{5}M_E R_E^2}T = \frac{5m}{3M_E}T$$

Substitute numerical values and evaluate ΔT:

$$\Delta T = \frac{5(2.3\times10^{19}\,\text{kg})}{3(6\times10^{24}\,\text{kg})}(1\,\text{d}) = 6.39\times10^{-6}\,\text{d} = 6.39\times10^{-6}\,\text{d}\times\frac{24\,\text{h}}{\text{d}}\times\frac{3600\,\text{s}}{\text{h}} = \boxed{0.552\,\text{s}}$$

27 •

Picture the Problem We can use $L = mvr$ to find the angular momentum of the particle. In (*b*) we can solve the equation $L = \sqrt{\ell(\ell+1)}\hbar$ for $\ell(\ell+1)$ and the approximate value of ℓ.

(*a*) Use the definition of angular momentum to obtain:

$$L = mvr = (2\times10^{-3}\ \text{kg})(3\times10^{-3}\ \text{m/s})(4\times10^{-3}\ \text{m}) = \boxed{2.40\times10^{-8}\ \text{kg}\cdot\text{m}^2/\text{s}}$$

(*b*) Solve the equation $L = \sqrt{\ell(\ell+1)}\hbar$ for $\ell(\ell+1)$:

$$\ell(\ell+1) = \frac{L^2}{\hbar^2}$$

Substitute numerical values and evaluate $\ell(\ell+1)$:

$$\ell(\ell+1) = \left(\frac{2.40\times10^{-8}\ \text{kg}\cdot\text{m}^2/\text{s}}{1.05\times01^{-34}\ \text{J}\cdot\text{s}}\right)^2 = \boxed{5.22\times10^{52}}$$

Because $\ell >> 1$, approximate its value with the square root of $\ell(\ell+1)$:

$$\ell \approx \boxed{2.29\times10^{26}}$$

(*c*) The quantization of angular momentum is not noticed in macroscopic physics because no experiment can differentiate between $\ell = 2\times10^{26}$ and $\ell = 2\times10^{26} + 1$.

***28** ••

Picture the Problem We can use conservation of angular momentum in part (*a*) to relate the before-and-after collapse rotation rates of the sun. In part (*b*), we can express the fractional change in the rotational kinetic energy of the sun as it collapses into a neutron star to decide whether its rotational kinetic energy is greater initially or after the collapse.

(*a*) Use conservation of angular momentum to relate the angular momenta of the sun before and after its collapse:

$$I_b\omega_b = I_a\omega_a \qquad (1)$$

Using the given formula, approximate the moment of inertia I_b of the sun before collapse:

$$I_b = 0.059MR_{sun}^2 = 0.059(1.99\times10^{30}\ \text{kg})(6.96\times10^5\ \text{km})^2 = 5.69\times10^{46}\ \text{kg}\cdot\text{m}^2$$

Find the moment of inertia I_a of the sun when it has collapsed into a spherical neutron star of radius 10 km and uniform mass distribution:

$$I_a = \tfrac{2}{5}MR^2 = \tfrac{2}{5}\left(1.99\times10^{30}\text{ kg}\right)\left(10\text{ km}\right)^2 = 7.96\times10^{37}\text{ kg}\cdot\text{m}^2$$

Substitute in equation (1) and solve for ω_a to obtain:

$$\omega_a = \frac{I_b}{I_a}\omega_b = \frac{5.69\times10^{46}\text{ kg}\cdot\text{m}^2}{7.96\times10^{37}\text{ kg}\cdot\text{m}^2}\omega_b = 7.15\times10^{8}\,\omega_b$$

Given that ω_b = 1 rev/25 d, evaluate ω_a:

$$\omega_a = 7.15\times10^{8}\left(\frac{1\text{ rev}}{25\text{ d}}\right) = \boxed{2.86\times10^{7}\text{ rev/d}}$$

The additional rotational kinetic energy comes at the expense of gravitational potential energy, which decreases as the sun gets smaller.

Note that the rotational period decreases by the same factor of I_b/I_a and becomes:

$$T_a = \frac{2\pi}{\omega_a} = \frac{2\pi}{2.86\times10^{7}\,\dfrac{\text{rev}}{\text{d}}\times\dfrac{2\pi\text{ rad}}{\text{rev}}\times\dfrac{1\text{d}}{24\text{h}}\times\dfrac{1\text{h}}{3600\text{s}}} = 3.02\times10^{-3}\text{ s}$$

(*b*) Express the fractional change in the sun's rotational kinetic energy as a consequence of its collapse and simplify to obtain:

$$\frac{\Delta K}{K_b} = \frac{K_a - K_b}{K_b} = \frac{K_a}{K_b} - 1 = \frac{\tfrac{1}{2}I_a\omega_a^2}{\tfrac{1}{2}I_b\omega_b^2} - 1 = \frac{I_a\omega_a^2}{I_b\omega_b^2} - 1$$

Substitute numerical values and evaluate $\Delta K/K_b$:

$$\frac{\Delta K}{K_b} = \left(\frac{1}{7.15\times10^{8}}\right)\left(\frac{2.86\times10^{7}\text{ rev/d}}{1\text{ rev/25 d}}\right)^2 - 1 = \boxed{7.15\times10^{8}}$$ (i.e., the rotational kinetic energy *increases* by a factor of approximately 7×10^{8}.)

29 ••

Picture the Problem We can solve $I = CMR^2$ for C and substitute numerical values in order to determine an experimental value of C for the earth. We can then compare this value to those for a spherical shell and a sphere in which the mass is uniformly distributed to decide whether the earth's mass density is greatest near its core or near its crust.

(*a*) Express the moment of inertia of the earth in terms of the constant *C*:

$$I = CMR^2$$

Solve for *C* to obtain:

$$C = \frac{I}{MR^2}$$

Substitute numerical values and evaluate *C*:

$$C = \frac{8.03\times10^{37}\ \text{kg}\cdot\text{m}^2}{\left(5.98\times10^{24}\ \text{kg}\right)\left(6370\ \text{km}\right)^2} = \boxed{0.331}$$

(*b*) If all of the mass were in the crust, the moment of inertia of the earth would be that of a thin spherical shell:

$$I_{\text{spherical shell}} = \tfrac{2}{3}MR^2$$

If the mass of the earth were uniformly distributed throughout its volume, its moment of inertia would be:

$$I_{\text{solid sphere}} = \tfrac{2}{5}MR^2$$

Because experimentally $C < 2/5 = 0.4$, the mass density must be greater near the center of the earth.

***30 ••**

Picture the Problem Let's estimate that the diver with arms extended over head is about 2.5 m long and has a mass $M = 80$ kg. We'll also assume that it is reasonable to model the diver as a uniform stick rotating about its center of mass. From the photo, it appears that he sprang about 3 m in the air, and that the diving board was about 3 m high. We can use these assumptions and estimated quantities, together with their definitions, to estimate ω and *L*.

Express the diver's angular velocity ω and angular momentum *L*:

$$\omega = \frac{\Delta\theta}{\Delta t} \qquad (1)$$

and

$$L = I\omega \qquad (2)$$

Using a constant-acceleration equation, express his time in the air:

$$\Delta t = \Delta t_{\text{rise 3 m}} + \Delta t_{\text{fall 6 m}} = \sqrt{\frac{2\Delta y_{\text{up}}}{g}} + \sqrt{\frac{2\Delta y_{\text{down}}}{g}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \sqrt{\frac{2(3\ \text{m})}{9.81\ \text{m/s}^2}} + \sqrt{\frac{2(6\ \text{m})}{9.81\ \text{m/s}^2}} = 1.89\ \text{s}$$

Estimate the angle through which he rotated in 1.89 s:

$$\Delta\theta \approx 0.5\ \text{rev} = \pi\ \text{rad}$$

Substitute in equation (1) and evaluate ω:

$$\omega = \frac{\pi\ \text{rad}}{1.89\ \text{s}} = \boxed{1.66\ \text{rad/s}}$$

Use the "stick rotating about an axis through its center of mass" model to approximate the moment of inertia of the diver:

$$I = \tfrac{1}{12}ML^2$$

Substitute in equation (2) to obtain:

$$L = \tfrac{1}{12}ML^2\omega$$

Substitute numerical values and evaluate L:

$$L = \tfrac{1}{12}(80\ \text{kg})(2.5\ \text{m})^2(1.66\ \text{rad/s})$$
$$= 69.2\ \text{kg}\cdot\text{m}^2/\text{s} \approx \boxed{70\ \text{kg}\cdot\text{m}^2/\text{s}}$$

Remarks: We can check the reasonableness of this estimation in another way. Because he rose about 3 m in the air, the initial impulse acting on him must be about 600 kg·m/s (i.e., $I = \Delta p = Mv_i$). If we estimate that the lever arm of the force is roughly ℓ = 1.5 m, and the angle between the force exerted by the board and a line running from his feet to the center of mass is about 5°, we obtain $L = I\ell\sin 5° \approx 78$ kg·m^2/s, which is not too bad considering the approximations made here.

31 ••

Picture the Problem First we assume a spherical diver whose mass M = 80 kg and whose diameter, when curled into a ball, is 1 m. We can estimate his angular velocity when he has curled himself into a ball from the ratio of his angular momentum to his moment of inertia. To estimate his angular momentum, we'll guess that the lever arm ℓ of the force that launches him from the diving board is about 1.5 m and that the angle between the force exerted by the board and a line running from his feet to the center of mass is about 5°.

Express the diver's angular velocity ω when he curls himself into a ball in mid-dive:

$$\omega = \frac{L}{I} \qquad (1)$$

Using a constant-acceleration equation, relate the speed with which he left the diving board v_0 to his maximum height Δy and our estimate of his angle with the vertical direction:

$$0 = v_{0y}^2 + 2a_y\Delta y$$
where
$$v_{0y} = v_0\cos 5°$$

Solve for v_0:

$$v_0 = \sqrt{\frac{2g\Delta y}{\cos^2 5°}}$$

Substitute numerical values and evaluate v_0:

$$v_0 = \frac{\sqrt{2(9.81\ \text{m/s}^2)(3\ \text{m})}}{\cos 5°} = 7.70\ \text{m/s}$$

Approximate the impulse acting on the diver to launch him with the speed v_0:

$$I = \Delta p = Mv_0$$

Letting ℓ represent the lever arm of the force acting on the diver as he leaves the diving board, express his angular momentum:

$$L = I\ell \sin 5° = Mv_0\ell \sin 5°$$

Use the "uniform sphere" model to approximate the moment of inertia of the diver:

$$I = \tfrac{2}{5}MR^2$$

Substitute in equation (1) to obtain:

$$\omega = \frac{Mv_0\ell \sin 5°}{\tfrac{2}{5}MR^2} = \frac{5v_0\ell \sin 5°}{2R^2}$$

Substitute numerical values and evaluate ω:

$$\omega = \frac{5(7.70\,\text{m/s})(1.5\,\text{m})\sin 5°}{2(0.5\,\text{m})^2} = \boxed{10.1\,\text{rad/s}}$$

***32 ••**

Picture the Problem We'll assume that he launches himself at an angle of 45° with the horizontal with his arms spread wide, and then pulls them in to increase his rotational speed during the jump. We'll also assume that we can model him as a 2-m long cylinder with an average radius of 0.15 m and a mass of 60 kg. We can then find his take-off speed and "air time" using constant-acceleration equations, and use the latter, together with the definition of rotational velocity, to find his initial rotational velocity. Finally, we can apply conservation of angular momentum to find his initial angular momentum.

Using a constant-acceleration equation, relate his takeoff speed v_0 to his maximum elevation Δy:

$$v^2 = v_{0y}^2 + 2a_y\Delta y$$

or, because $v_{0y} = v_0\sin 45°$, $v = 0$, and $a_y = -g$,

$$0 = v_0^2 \sin^2 45° - 2g\Delta y$$

Solve for v_0 to obtain:

$$v_0 = \sqrt{\frac{2g\Delta y}{\sin^2 45°}} = \frac{\sqrt{2g\Delta y}}{\sin 45°}$$

Substitute numerical values and evaluate v_0:

$$v_0 = \frac{\sqrt{2(9.81\,\text{m/s}^2)(0.6\,\text{m})}}{\sin 45°} = \boxed{4.85\,\text{m/s}}$$

Use its definition to express Goebel's angular velocity:

$$\omega = \frac{\Delta\theta}{\Delta t}$$

Use a constant-acceleration equation to express Goebel's "air time" Δt:

$$\Delta t = 2\Delta t_{\text{rise}\,0.6\,\text{m}} = 2\sqrt{\frac{2\Delta y}{g}}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = 2\sqrt{\frac{2(0.6\,\text{m})}{9.81\,\text{m/s}^2}} = 0.699\,\text{s}$$

Substitute numerical values and evaluate ω:

$$\omega = \frac{4\,\text{rev}}{0.699\,\text{s}} \times \frac{2\pi\,\text{rad}}{\text{rev}} = \boxed{36.0\,\text{rad/s}}$$

Use conservation of angular momentum to relate his take-off angular velocity ω_0 to his average angular velocity ω as he performs a quadruple Lutz:

$$I_0\omega_0 = I\omega$$

Assuming that he can change his angular momentum by a factor of 2 by pulling his arms in, solve for and evaluate ω_0:

$$\omega_0 = \frac{I}{I_0}\omega = \frac{1}{2}(36\,\text{rad/s}) = \boxed{18.0\,\text{rad/s}}$$

Express his take-off angular momentum:

$$L_0 = I_0\omega_0$$

Assuming that we can model him as a solid cylinder of length ℓ with an average radius r and mass m, express his moment of inertia with arms drawn in (his take-off configuration):

$$I_0 = 2\left(\tfrac{1}{2}mr^2\right) = mr^2$$

where the factor of 2 represents our assumption that he can double his moment of inertia by extending his arms.

Substitute to obtain:

$$L_0 = mr^2\omega_0$$

Substitute numerical values and evaluate L_0:

$$L_0 = (60\,\text{kg})(0.15\,\text{m})^2(18\,\text{rad/s}) = \boxed{24.3\,\text{kg}\cdot\text{m}^2/\text{s}}$$

Vector Nature of Rotation

33 •

Picture the Problem We can express $\vec{F}$ and $\vec{r}$ in terms of the unit vectors $\hat{i}$ and $\hat{j}$ and then use the definition of the cross product to find $\vec{\tau}$.

Express $\vec{F}$ in terms of F and the unit vector $\hat{i}$:

$$\vec{F} = -F\hat{i}$$

Express $\vec{r}$ in terms of R and the unit vector $\hat{j}$:

$$\vec{r} = R\hat{j}$$

Calculate the cross product of $\vec{r}$ and $\vec{F}$:

$$\vec{\tau} = \vec{r} \times \vec{F} = FR\left(\hat{j} \times -\hat{i}\right) = FR\left(\hat{i} \times \hat{j}\right) = \boxed{FR\hat{k}}$$

34 •

Picture the Problem We can find the torque is the cross product of $\vec{r}$ and $\vec{F}$.

Compute the cross product of $\vec{r}$ and $\vec{F}$:

$$\vec{\tau} = \vec{r} \times \vec{F} = \left(x\hat{i} + y\hat{j}\right)\left(-mg\hat{j}\right) = -mgx\left(\hat{i} \times \hat{j}\right) - mgy\left(\hat{j} \times \hat{j}\right) = \boxed{-mgx\hat{k}}$$

35 •

Picture the Problem The cross product of the vectors $\vec{A} = A_x\hat{i} + A_y\hat{j}$ and $\vec{B} = B_x\hat{i} + B_y\hat{j}$ is given by

$$\vec{A} \times \vec{B} = A_xB_x\left(\hat{i} \times \hat{i}\right) + A_xB_y\left(\hat{i} \times \hat{j}\right) + A_yB_x\left(\hat{j} \times \hat{i}\right) + A_yB_y\left(\hat{j} \times \hat{j}\right)$$
$$= A_xB_x(0) + A_xB_y\left(\hat{k}\right) + A_yB_x\left(-\hat{k}\right) + A_yB_y(0)$$
$$= A_xB_y\left(\hat{k}\right) + A_yB_x\left(-\hat{k}\right)$$

(*a*) Find $\vec{A} \times \vec{B}$ for $\vec{A} = 4\hat{i}$ and $\vec{B} = 6\hat{i} + 6\hat{j}$:

$$\vec{A} \times \vec{B} = 4\hat{i} \times \left(6\hat{i} + 6\hat{j}\right) = 24\left(\hat{i} \times \hat{i}\right) + 24\left(\hat{i} \times \hat{j}\right) = 24(0) + 24\hat{k} = \boxed{24\hat{k}}$$

(*b*) Find $\vec{A} \times \vec{B}$ for $\vec{A} = 4\hat{i}$ and $\vec{B} = 6\hat{i} + 6\hat{k}$:

$$\vec{A} \times \vec{B} = 4\hat{i} \times \left(6\hat{i} + 6\hat{k}\right) = 24\left(\hat{i} \times \hat{i}\right) + 24\left(\hat{i} \times \hat{k}\right) = 24(0) + 24\left(-\hat{j}\right) = \boxed{-24\hat{j}}$$

(*c*) Find $\vec{A} \times \vec{B}$ for $\vec{A} = 2\hat{i} + 3\hat{j}$ and $\vec{B} = 3\hat{i} + 2\hat{j}$:

$$\vec{A} \times \vec{B} = \left(2\hat{i} + 3\hat{j}\right) \times \left(3\hat{i} + 2\hat{j}\right) = 6\left(\hat{i} \times \hat{i}\right) + 4\left(\hat{i} \times \hat{j}\right) + 9\left(\hat{j} \times \hat{i}\right) + 6\left(\hat{j} \times \hat{j}\right)$$
$$= 6(0) + 4\left(\hat{k}\right) + 9\left(-\hat{k}\right) + 6(0) = \boxed{-5\hat{k}}$$

***36 •**

Picture the Problem The magnitude of $\vec{A}\times\vec{B}$ is given by $|AB\sin\theta|$.

Equate the magnitudes of $\vec{A}\times\vec{B}$ and $\vec{A}\cdot\vec{B}$:

$$|AB\sin\theta| = |AB\cos\theta|$$

$$\therefore |\sin\theta| = |\cos\theta|$$

or

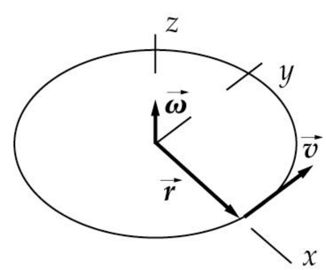
$$\tan\theta = \pm 1$$

Solve for θ to obtain:

$$\theta = \tan^{-1}\pm 1 = \boxed{\pm 45^\circ \text{ or } \pm 135^\circ}$$

37 ••

Picture the Problem Let $\vec{r}$ be in the *xy* plane. Then $\vec{\omega}$ points in the positive *z* direction. We can establish the results called for in this problem by forming the appropriate cross products and by differentiating $\vec{v}$.



(*a*) Express $\vec{\omega}$ using unit vectors:

$$\vec{\omega} = \omega\hat{k}$$

Express $\vec{r}$ using unit vectors:

$$\vec{r} = r\hat{i}$$

Form the cross product of $\vec{\omega}$ and $\vec{r}$:

$$\vec{\omega}\times\vec{r} = \omega\hat{k}\times r\hat{i} = r\omega\left(\hat{k}\times\hat{i}\right) = r\omega\,\hat{j}$$
$$= v\hat{j}$$

$$\therefore \boxed{\vec{v} = \vec{\omega}\times\vec{r}}$$

(*b*) Differentiate $\vec{v}$ with respect to *t* to express $\vec{a}$:

$$\vec{a} = \frac{d\vec{v}}{dt} = \frac{d}{dt}\left(\vec{\omega}\times\vec{r}\right)$$
$$= \frac{d\vec{\omega}}{dt}\times\vec{r} + \vec{\omega}\times\frac{d\vec{r}}{dt}$$
$$= \frac{d\vec{\omega}}{dt}\times\vec{r} + \vec{\omega}\times\vec{v}$$
$$= \vec{a}_t + \vec{\omega}\times\left(\vec{\omega}\times\vec{r}\right)$$
$$= \vec{a}_t + \vec{a}_c$$

where $\vec{a}_c = \boxed{\vec{\omega}\times\left(\vec{\omega}\times\vec{r}\right)}$

and $\vec{a}_t$ and $\vec{a}_c$ are the tangential and centripetal accelerations, respectively.

38 ••

Picture the Problem Because $B_z = 0$, we can express $\vec{B}$ as $\vec{B} = B_x\hat{i} + B_y\hat{j}$ and form its cross product with $\vec{A}$ to determine B_x and B_y.

Express $\vec{B}$ in terms of its components:

$$\vec{B} = B_x\hat{i} + B_y\hat{j} \qquad (1)$$

Express $\vec{A}\times\vec{B}$:

$$\vec{A}\times\vec{B} = 4\hat{i}\times\left(B_x\hat{i} + B_y\hat{j}\right) = 4B_y\hat{k} = 12\hat{k}$$

Solve for B_y:

$$B_y = 3$$

Relate B to B_x and B_y:

$$B^2 = B_x^2 + B_y^2$$

Solve for and evaluate B_x:

$$B_x = \sqrt{B^2 - B_y^2} = \sqrt{5^2 - 3^2} = 4$$

Substitute in equation (1):

$$\vec{B} = \boxed{4\hat{i} + 3\hat{j}}$$

39 •

Picture the Problem We can write $\vec{B}$ in the form $\vec{B} = B_x\hat{i} + B_y\hat{j} + B_z\hat{k}$ and use the dot product of $\vec{A}$ and $\vec{B}$ to find B_y and their cross product to find B_x and B_z.

Express $\vec{B}$ in terms of its components:

$$\vec{B} = B_x\hat{i} + B_y\hat{j} + B_z\hat{k} \qquad (1)$$

Evaluate $\vec{A}\cdot\vec{B}$:

$$\vec{A}\cdot\vec{B} = 3B_y = 12$$

and

$B_y = 4$

Evaluate $\vec{A}\times\vec{B}$:

$$\vec{A}\times\vec{B} = 3\hat{j}\times\left(B_x\hat{i} + 4\hat{j} + B_z\hat{k}\right)$$
$$= -3B_x\hat{k} + 3B_z\hat{i}$$

Because $\vec{A}\times\vec{B} = 9\hat{i}$:

$B_x = 0$ and $B_z = 3$.

Substitute in equation (1) to obtain:

$$\vec{B} = \boxed{4\hat{j} + 3\hat{k}}$$

40 ••

Picture the Problem The dot product of $\vec{A}$ with the cross product of $\vec{B}$ and $\vec{C}$ is a scalar quantity and can be expressed in determinant form as $\begin{vmatrix} a_x & a_y & a_z \\ b_x & b_y & b_z \\ c_x & c_y & c_z \end{vmatrix}$. We can expand this determinant by minors to show that it is equivalent to $\vec{A}\cdot(\vec{B}\times\vec{C})$, $\vec{C}\cdot(\vec{A}\times\vec{B})$, and $\vec{B}\cdot(\vec{C}\times\vec{A})$.

The dot product of $\vec{A}$ with the cross product of $\vec{B}$ and $\vec{C}$ is a scalar quantity and can be expressed in determinant form as:

$$\vec{A}\cdot(\vec{B}\times\vec{C}) = \begin{vmatrix} a_x & a_y & a_z \\ b_x & b_y & b_z \\ c_x & c_y & c_z \end{vmatrix}$$

Expand the determinant by minors to obtain:

$$\begin{vmatrix} a_x & a_y & a_z \\ b_x & b_y & b_z \\ c_x & c_y & c_z \end{vmatrix} = a_x b_y c_z - a_x b_z c_y + a_y b_z c_x - a_y b_x c_z + a_z b_x c_y - a_z b_y c_x \quad (1)$$

Evaluate the cross product of $\vec{B}$ and $\vec{C}$ to obtain:

$$\vec{B}\times\vec{C} = \left(b_y c_z - b_z c_y\right)\hat{i} + \left(b_z c_x - b_x c_z\right)\hat{j} + \left(b_x c_y - b_y c_x\right)\hat{k}$$

Form the dot product of $\vec{A}$ with $\vec{B}\times\vec{C}$ to obtain:

$$\vec{A}\cdot\left(\vec{B}\times\vec{C}\right) = a_x b_y c_z - a_x b_z c_y + a_y b_z c_x - a_y b_x c_z + a_z b_x c_y - a_z b_y c_x \quad (2)$$

Because (1) and (2) are the same, we can conclude that:

$$\boxed{\vec{A}\cdot(\vec{B}\times\vec{C}) = \begin{vmatrix} a_x & a_y & a_z \\ b_x & b_y & b_z \\ c_x & c_y & c_z \end{vmatrix}}$$

Proceed as above to establish that:

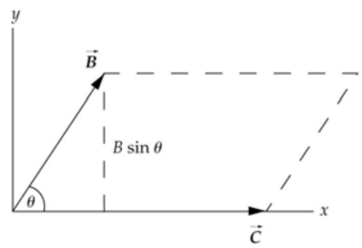
$$\boxed{\vec{C}\cdot(\vec{A}\times\vec{B}) = \begin{vmatrix} a_x & a_y & a_z \\ b_x & b_y & b_z \\ c_x & c_y & c_z \end{vmatrix}}$$

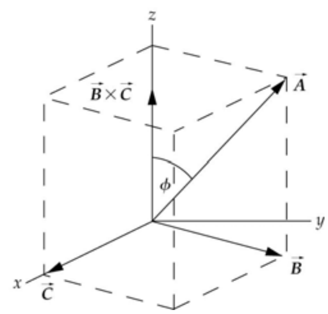
and

$$\boxed{\vec{B}\cdot(\vec{C}\times\vec{A})=\begin{vmatrix}a_x & a_y & a_z\\ b_x & b_y & b_z\\ c_x & c_y & c_z\end{vmatrix}}$$

41 ••

Picture the Problem Let, without loss of generality, the vector $\vec{C}$ lie along the *x* axis and the vector $\vec{B}$ lie in the *xy* plane as shown below to the left. The diagram to the right shows the parallelepiped spanned by the three vectors. We can apply the definitions of the cross- and dot-products to show that $\vec{A}\cdot(\vec{B}\times\vec{C})$ is the volume of the parallelepiped.





Express the cross-product of $\vec{B}$ and $\vec{C}$:

$$\vec{B}\times\vec{C}=(BC\sin\theta)(-\hat{k})$$

and

$$\left|\vec{B}\times\vec{C}\right|=(B\sin\theta)C$$

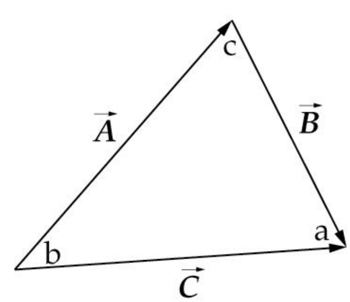
$$=\text{area of the parallelogram}$$

Form the dot-product of $\vec{A}$ with the cross-product of $\vec{B}$ and $\vec{C}$ to obtain:

$$\begin{aligned}\vec{A}\cdot(\vec{B}\times\vec{C})&=A(B\sin\theta)C\cos\phi\\&=(BC\sin\theta)(A\cos\phi)\\&=(\text{area of base})(\text{height})\\&=\boxed{V_{\text{parallelepiped}}}\end{aligned}$$

***42 ••**

Picture the Problem Draw the triangle using the three vectors as shown below. Note that $\vec{A}+\vec{B}=\vec{C}$. We can find the magnitude of the cross product of $\vec{A}$ and $\vec{B}$ and of $\vec{A}$ and $\vec{C}$ and then use the cross product of $\vec{A}$ and $\vec{C}$, using $\vec{A}+\vec{B}=\vec{C}$, to show that $AC\sin b=AB\sin c$ or $B/\sin b=C/\sin c$. Proceeding similarly, we can extend the law of sines to the third side of the triangle and the angle opposite it.



Express the magnitude of the cross product of $\vec{A}$ and $\vec{B}$: $\left|\vec{A}\times\vec{B}\right| = AB\sin c$

Express the magnitude of the cross product of $\vec{A}$ and $\vec{C}$: $\left|\vec{A}\times\vec{C}\right| = AC\sin b$

Form the cross product of $\vec{A}$ with $\vec{C}$ to obtain:

$$\vec{A}\times\vec{C} = \vec{A}\times\left(\vec{A}+\vec{B}\right) = \vec{A}\times\vec{A}+\vec{A}\times\vec{B} = \vec{A}\times\vec{B}$$

because $\vec{A}\times\vec{A} = 0$.

Because $\vec{A}\times\vec{C} = \vec{A}\times\vec{B}$:

$$\left|\vec{A}\times\vec{C}\right| = \left|\vec{A}\times\vec{B}\right|$$

and

$$AC\sin b = AB\sin c$$

Simplify and rewrite this expression to obtain:

$$\boxed{\frac{B}{\sin b} = \frac{C}{\sin c}}$$

Proceed similarly to extend this result to the law of sines:

$$\boxed{\frac{A}{\sin a} = \frac{B}{\sin b} = \frac{C}{\sin c}}$$

Angular Momentum

43 •

Picture the Problem $\vec{L}$ and $\vec{p}$ are related according to $\vec{L} = \vec{r}\times\vec{p}$. If $\vec{L} = 0$, then examination of the magnitude of $\vec{r}\times\vec{p}$ will allow us to conclude that $\sin\phi = 0$ and that the particle is moving either directly toward the point, directly away from the point, or through the point.

Because $\vec{L} = 0$:

$$\vec{r}\times\vec{p} = \vec{r}\times m\vec{v} = m\vec{r}\times\vec{v} = 0$$

or

$$\vec{r}\times\vec{v} = 0$$

Express the magnitude of $\vec{r}\times\vec{v}$: $\left|\vec{r}\times\vec{v}\right| = rv\sin\phi = 0$

Because neither r nor v is zero: $\sin\phi = 0$

where ϕ is the angle between $\vec{r}$ and $\vec{v}$.

Solve for ϕ: $\phi = \sin^{-1}0 = \boxed{0° \text{ or } 180°}$

44 •

Picture the Problem We can use their definitions to calculate the angular momentum and moment of inertia of the particle and the relationship between L, I, and ω to determine its angular speed.

(*a*) Express and evaluate the magnitude of $\vec{L}$:

$$L = mvr = (2\,\text{kg})(3.5\,\text{m/s})(4\,\text{m}) = \boxed{28.0\,\text{kg}\cdot\text{m}^2/\text{s}}$$

(*b*) Express the moment of inertia of the particle with respect to an axis through the center of the circle in which it is moving:

$$I = mr^2 = (2\,\text{kg})(4\,\text{m})^2 = \boxed{32\,\text{kg}\cdot\text{m}^2}$$

(*c*) Relate the angular speed of the particle to its angular momentum and solve for and evaluate ω:

$$\omega = \frac{L}{I} = \frac{28.0\,\text{kg}\cdot\text{m}^2/\text{s}}{32\,\text{kg}\cdot\text{m}^2} = \boxed{0.875\,\text{rad/s}^2}$$

45 •

Picture the Problem We can use the definition of angular momentum to calculate the angular momentum of this particle and the relationship between its angular momentum and angular speed to describe the variation in its angular speed with time.

(*a*) Express the angular momentum of the particle as a function of its mass, speed, and distance of its path from the reference point:

$$L = rmv\sin\theta = (6\,\text{m})(2\,\text{kg})(4.5\,\text{m/s})\sin 90° = \boxed{54.0\,\text{kg}\cdot\text{m}^2/\text{s}}$$

(*b*) Because $L = mr^2\omega$:

$$\omega \propto \frac{1}{r^2}$$ and

$\boxed{\omega \text{ increases as the particle approaches the point and decreases as it recedes.}}$

***46** ••

Picture the Problem We can use the formula for the area of a triangle to find the area swept out at $t = t_1$, add this area to the area swept out in time dt, and then differentiate this expression with respect to time to obtain the given expression for dA/dt.

Express the area swept out at $t = t_1$:

$$A_1 = \tfrac{1}{2}br_1\cos\theta_1 = \tfrac{1}{2}bx_1$$

where θ_1 is the angle between $\vec{r}_1$ and $\vec{v}$ and

x_1 is the component of $\vec{r}_1$ in the direction of $\vec{v}$.

Express the area swept out at $t = t_1 + dt$:

$$A = A_1 + dA = \tfrac{1}{2}b(x_1 + dx) = \tfrac{1}{2}b(x_1 + vdt)$$

Differentiate with respect to t:

$$\frac{dA}{dt} = \tfrac{1}{2}b\frac{dx}{dt} = \tfrac{1}{2}bv = \text{constant}$$

Because $r\sin\theta = b$:

$$\tfrac{1}{2}bv = \tfrac{1}{2}(r\sin\theta)v = \frac{1}{2m}(rp\sin\theta) = \boxed{\frac{L}{2m}}$$

47 ••

Picture the Problem We can find the total angular momentum of the coin from the sum of its spin and orbital angular momenta.

(*a*) Express the spin angular momentum of the coin:

$$L_{\text{spin}} = I_{\text{cm}}\omega_{\text{spin}}$$

From Problem 9-44:

$$I = \tfrac{1}{4}MR^2$$

Substitute for I to obtain:

$$L_{\text{spin}} = \tfrac{1}{4}MR^2\omega_{\text{spin}}$$

Substitute numerical values and evaluate L_{spin}:

$$L_{\text{spin}} = \tfrac{1}{4}(0.015\,\text{kg})(0.0075\,\text{m})^2 \times \left(10\frac{\text{rev}}{\text{s}} \times \frac{2\pi\,\text{rad}}{\text{rev}}\right) = \boxed{1.33\times10^{-5}\,\text{kg}\cdot\text{m}^2/\text{s}}$$

(*b*) Express and evaluate the total angular momentum of the coin:

$$L = L_{\text{orbit}} + L_{\text{spin}} = 0 + L_{\text{spin}} = \boxed{1.33\times10^{-5}\,\text{kg}\cdot\text{m}^2/\text{s}}$$

(*c*) From Problem 10-14:

$$L_{\text{orbit}} = 0$$

and

$$L = \boxed{1.33\times10^{-5}\,\text{kg}\cdot\text{m}^2/\text{s}}$$

(*d*) Express the total angular momentum of the coin:

$$L = L_{\text{orbit}} + L_{\text{spin}}$$

Find the orbital momentum of the coin:

$$L_{\text{orbit}} = \pm MvR = \pm(0.015\,\text{kg})(0.05\,\text{m/s})(0.1\,\text{m}) = \pm 7.50\times10^{-5}\,\text{kg}\cdot\text{m}^2/\text{s}$$

where the ± is a consequence of the fact that the coin's direction is not specified.

Substitute to obtain:

$$L = \pm 7.50\times10^{-5}\,\text{kg}\cdot\text{m}^2/\text{s} + 1.33\times10^{-5}\,\text{kg}\cdot\text{m}^2/\text{s}$$

The possible values for L are:

$$L = \boxed{8.83\times10^{-5}\,\text{kg}\cdot\text{m}^2/\text{s}}$$

or

$$L = \boxed{-6.17\times10^{-5}\,\text{kg}\cdot\text{m}^2/\text{s}}$$

48 ••

Picture the Problem Both the forces acting on the particles exert torques with respect to an axis perpendicular to the page and through point O and the net torque about this axis is their vector sum.

Express the net torque about an axis perpendicular to the page and through point O:

$$\vec{\boldsymbol{\tau}}_{\text{net}} = \sum_i \vec{\boldsymbol{\tau}}_i = \vec{\mathbf{r}}_1\times\vec{\mathbf{F}}_1 + \vec{\mathbf{r}}_2\times\vec{\mathbf{F}}_2 = (\vec{\mathbf{r}}_1 - \vec{\mathbf{r}}_2)\times\vec{\mathbf{F}}_1$$

because $\vec{F}_2 = -\vec{F}_1$

Because $\vec{r}_1 - \vec{r}_2$ points along $-\vec{F}_1$:

$$\boxed{(\vec{r}_1 - \vec{r}_2)\times\vec{F}_1 = 0}$$

Torque and Angular Momentum

49 •

Picture the Problem The angular momentum of the particle changes because a *net* torque acts on it. Because we know how the angular momentum depends on time, we can find the net torque acting on the particle by differentiating its angular momentum. We can use a constant-acceleration equation and Newton's 2nd law to relate the angular speed of the particle to its angular acceleration.

(*a*) Relate the magnitude of the torque acting on the particle to the rate at which its angular momentum changes:

$$\tau_{\text{net}} = \frac{dL}{dt} = \frac{d}{dt}\left[(4\,\text{N}\cdot\text{m})t\right] = \boxed{4.00\,\text{N}\cdot\text{m}}$$

(*b*) Using a constant-acceleration equation, relate the angular speed of the particle to its acceleration and time-in-motion:

$$\omega = \omega_0 + \alpha t$$

where $\omega_0 = 0$

Use Newton's 2nd law to relate the angular acceleration of the particle to
the net torque acting on it:

$$\alpha = \frac{\tau_{net}}{I} = \frac{\tau_{net}}{mr^2}$$

Substitute to obtain:

$$\omega = \frac{\tau_{net}}{mr^2} t$$

Substitute numerical values and evaluate ω:

$$\omega = \frac{(4\ \text{N} \cdot \text{m})t}{(1.8\,\text{kg})(3.4\,\text{m})^2} = \boxed{(0.192\,\text{rad/s}^2)t}$$

provided t is in seconds.

50 ••

Picture the Problem The angular momentum of the cylinder changes because a *net* torque acts on it. We can find the angular momentum at $t = 25$ s from its definition and the *net* torque acting on the cylinder from the rate at which the angular momentum is changing. The magnitude of the frictional force acting on the rim can be found using the definition of torque.

(*a*) Use its definition to express the angular momentum of the cylinder:

$$L = I\omega = \tfrac{1}{2}mr^2\omega$$

Substitute numerical values and evaluate L:

$$L = \tfrac{1}{2}(90\,\text{kg})(0.4\,\text{m})^2 \times \left(500\frac{\text{rev}}{\text{min}} \times \frac{2\pi\,\text{rad}}{\text{rev}} \times \frac{1\,\text{min}}{60\,\text{s}}\right) = \boxed{377\,\text{kg} \cdot \text{m}^2/\text{s}}$$

(*b*) Express and evaluate $\frac{dL}{dt}$:

$$\frac{dL}{dt} = \frac{(377\,\text{kg} \cdot \text{m}^2/\text{s})}{25\,\text{s}} = \boxed{15.1\,\text{kg} \cdot \text{m}^2/\text{s}^2}$$

(*c*) Because the torque acting on the uniform cylinder is constant, the rate

$$\tau = \frac{dL}{dt} = \boxed{15.1\,\text{kg} \cdot \text{m}^2/\text{s}^2}$$

of change of the angular momentum is constant and hence the instantaneous rate of change of the angular momentum at any instant is equal to the average rate of change over the time during which the torque acts:

(*d*) Using the definition of torque that relates the applied force to its lever arm, express the magnitude of the frictional force *f* acting on the rim:

$$f = \frac{\tau}{\ell} = \frac{15.1\,\text{kg}\cdot\text{m}^2/\text{s}^2}{0.4\,\text{m}} = \boxed{37.7\,\text{N}}$$

***51** ••

Picture the Problem Let the system include the pulley, string, and the blocks and assume that the mass of the string is negligible. The angular momentum of this system changes because a *net* torque acts on it.

(*a*) Express the net torque about the center of mass of the pulley:

$$\tau_{\text{net}} = Rm_2 g\sin\theta - Rm_1 g = \boxed{Rg(m_2\sin\theta - m_1)}$$

where we have taken clockwise to be positive to be consistent with a positive upward velocity of the block whose mass is m_1 as indicated in the figure.

(*b*) Express the total angular momentum of the system about an axis through the center of the pulley:

$$L = I\omega + m_1 vR + m_2 vR = \boxed{vR\left(\frac{I}{R^2} + m_1 + m_2\right)}$$

(*c*) Express τ as the time derivative of the angular momentum:

$$\tau = \frac{dL}{dt} = \frac{d}{dt}\left[vR\left(\frac{I}{R^2} + m_1 + m_2\right)\right] = aR\left(\frac{I}{R^2} + m_1 + m_2\right)$$

Equate this result to that of part (*a*) and solve for *a* to obtain:

$$a = \boxed{\frac{g(m_2\sin\theta - m_1)}{\dfrac{I}{R^2} + m_1 + m_2}}$$

52 ••

Picture the Problem The forces resulting from the release of gas from the jets will exert a torque on the spaceship that will slow and eventually stop its rotation. We can relate this net torque to the angular momentum of the spaceship and to the time the jets must fire.

Relate the firing time of the jets to the desired change in angular momentum:

$$\Delta t = \frac{\Delta L}{\tau_{\text{net}}} = \frac{I\Delta\omega}{\tau_{\text{net}}}$$

Express the magnitude of the net torque exerted by the jets:

$$\tau_{\text{net}} = 2FR$$

Letting $\Delta m/\Delta t'$ represent the mass of gas per unit time exhausted from the jets, relate the force exerted by the gas on the spaceship to the rate at which the gas escapes:

$$F = \frac{\Delta m}{\Delta t'}v$$

Substitute and solve for Δt to obtain:

$$\Delta t = \frac{I\Delta\omega}{2\dfrac{\Delta m}{\Delta t'}vR}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{\left(4000\,\text{kg}\cdot\text{m}^2\right)\left(6\dfrac{\text{rev}}{\text{min}}\times\dfrac{2\pi\,\text{rad}}{\text{rev}}\times\dfrac{1\,\text{min}}{60\,\text{s}}\right)}{2\left(10^{-2}\,\text{kg/s}\right)\left(800\,\text{m/s}\right)\left(3\,\text{m}\right)} = \boxed{52.4\,\text{s}}$$

53 ••

Picture the Problem We can use constant-acceleration equations to express the projectile's position and velocity coordinates as functions of time. We can use these coordinates to express the particle's position and velocity vectors $\vec{r}$ and $\vec{v}$. Using its definition, we can express the projectile's angular momentum $\vec{L}$ as a function of time and then differentiate this expression to obtain $d\vec{L}/dt$. Finally, we can use the definition of the torque, relative to an origin located at the launch position, the gravitational force exerts on the projectile to express $\vec{\tau}$ and complete the demonstration that $d\vec{L}/dt = \vec{\tau}$.

Using its definition, express the angular momentum vector $\vec{L}$ of the projectile:

$$\vec{L} = \vec{r}\times m\vec{v} \qquad (1)$$

Using constant-acceleration

$$x = v_{0x}t = \left(V\cos\theta\right)t$$

equations, express the position coordinates of the projectile as a function of time:

and

$$y = y_0 + v_{0y}t + \tfrac{1}{2}a_y t^2 = (V\sin\theta)t - \tfrac{1}{2}gt^2$$

Express the projectile's position vector $\vec{r}$:

$$\vec{r} = [(V\cos\theta)t]\hat{i} + \left[(V\sin\theta)t - \tfrac{1}{2}gt^2\right]\hat{j}$$

Using constant-acceleration equations, express the velocity of the projectile as a function of time:

$$v_x = v_{0x} = V\cos\theta$$

and

$$v_y = v_{0y} + a_y t = V\sin\theta - gt$$

Express the projectile's velocity vector $\vec{v}$:

$$\vec{v} = [V\cos\theta]\hat{i} + [V\sin\theta - gt]\hat{j}$$

Substitute in equation (1) to obtain:

$$\vec{L} = \left\{[(V\cos\theta)t]\hat{i} + \left[(V\sin\theta)t - \tfrac{1}{2}gt^2\right]\hat{j}\right\} \times m\left\{[V\cos\theta]\hat{i} + [V\sin\theta - gt]\hat{j}\right\} = \left(-\tfrac{1}{2}mgt^2V\cos\theta\right)\hat{k}$$

Differentiate $\vec{L}$ with respect to t to obtain:

$$\frac{d\vec{L}}{dt} = \frac{d}{dt}\left(-\tfrac{1}{2}mgt^2V\cos\theta\right)\hat{k} = (-mgtV\cos\theta)\hat{k} \quad (2)$$

Using its definition, express the torque acting on the projectile:

$$\vec{\tau} = \vec{r}\times(-mg)\hat{j} = [(V\cos\theta)t]\hat{i} + \left[(V\sin\theta)t - \tfrac{1}{2}gt^2\right]\hat{j} \times (-mg)\hat{j}$$

or

$$\vec{\tau} = (-mgtV\cos\theta)\hat{k} \quad (3)$$

Comparing equations (2) and (3) we see that:

$$\boxed{\frac{d\vec{L}}{dt} = \vec{\tau}}$$

Conservation of Angular Momentum

***54** •

Picture the Problem Let m represent the mass of the planet and apply the definition of torque to find the torque produced by the gravitational force of attraction. We can use Newton's 2nd law of motion in the form $\vec{\tau} = d\vec{L}/dt$ to show that $\vec{L}$ is constant and apply conservation of angular momentum to the motion of the planet at points A and B.

(*a*) Express the torque produced by the gravitational force of attraction of the sun for the planet:

$\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{r}} \times \vec{\boldsymbol{F}} = \boxed{0}$ because $\vec{\boldsymbol{F}}$ acts along the direction of $\vec{\boldsymbol{r}}$.

(*b*) Because $\vec{\boldsymbol{\tau}} = 0$:

$$\frac{d\vec{\boldsymbol{L}}}{dt} = 0 \Rightarrow \vec{\boldsymbol{L}} = \vec{\boldsymbol{r}} \times m\vec{\boldsymbol{v}} = \text{constant}$$

Noting that at points *A* and *B* $|\vec{\boldsymbol{r}} \times \vec{\boldsymbol{v}}| = rv$, express the relationship between the distances from the sun and the speeds of the planets:

$$r_1 v_1 = r_2 v_2$$

or

$$\frac{v_1}{v_2} = \boxed{\frac{r_2}{r_1}}$$

55 ••

Picture the Problem Let the system consist of you, the extended weights, and the platform. Because the net external torque acting on this system is zero, its angular momentum remains constant during the pulling in of the weights.

(*a*) Using conservation of angular momentum, relate the initial and final angular speeds of the system to its initial and final moments of inertia:

$$I_\text{i}\omega_\text{i} = I_\text{f}\omega_\text{f}$$

Solve for ω_f:

$$\omega_\text{f} = \frac{I_\text{i}}{I_\text{f}}\omega_\text{i}$$

Substitute numerical values and evaluate ω_f:

$$\omega_\text{f} = \frac{6\,\text{kg}\cdot\text{m}^2}{1.8\,\text{kg}\cdot\text{m}^2}(1.5\,\text{rev/s}) = \boxed{5.00\,\text{rev/s}}$$

(*b*) Express the change in the kinetic energy of the system:

$$\Delta K = K_\text{f} - K_\text{i} = \tfrac{1}{2}I_\text{f}\omega_\text{f}^2 - \tfrac{1}{2}I_\text{i}\omega_\text{i}^2$$

Substitute numerical values and evaluate ΔK:

$$\Delta K = \tfrac{1}{2}(1.8\,\text{kg}\cdot\text{m}^2)\left(5\frac{\text{rev}}{\text{s}} \times \frac{2\pi\,\text{rad}}{\text{rev}}\right)^2 - \tfrac{1}{2}(6\,\text{kg}\cdot\text{m}^2)\left(1.5\frac{\text{rev}}{\text{s}} \times \frac{2\pi\,\text{rad}}{\text{rev}}\right)^2 = \boxed{622\,\text{J}}$$

(*c*) Because no external agent does work on the system, the energy comes from the internal energy of the man.

***56 ••**

Picture the Problem Let the system consist of the blob of putty and the turntable. Because the net external torque acting on this system is zero, its angular momentum remains constant when the blob of putty falls onto the turntable.

(*a*) Using conservation of angular momentum, relate the initial and final angular speeds of the turntable to its initial and final moments of inertia and solve for ω_f:

$$I_0\omega_i = I_f\omega_f$$

and

$$\omega_f = \frac{I_0}{I_f}\omega_i$$

Express the final rotational inertia of the turntable-plus-blob:

$$I_f = I_0 + I_{blob} = I_0 + mR^2$$

Substitute and simplify to obtain:

$$\omega_f = \frac{I_0}{I_0 + mR^2}\omega_i = \boxed{\frac{1}{1+\frac{mR^2}{I_0}}\omega_i}$$

(*b*) If the blob flies off tangentially to the turntable, its angular momentum doesn't change (with respect to an axis through the center of turntable). Because there is no external torque acting on the blob-turntable system, the total angular momentum of the system will remain constant and the angular momentum of the turntable will not change. Because the moment of inertia of the table hasn't changed either, the turntable will continue to spin at $\boxed{\omega' = \omega_f}$.

57 ••

Picture the Problem Because the net external torque acting on the Lazy Susan-cockroach system is zero, the net angular momentum of the system is constant (equal to zero because the Lazy Susan is initially at rest) and we can use conservation of angular momentum to find the angular velocity ω of the Lazy Susan. The speed of the cockroach relative to the floor v_f is the difference between its speed with respect to the Lazy Susan and the speed of the Lazy Susan at the location of the cockroach with respect to the floor.

Relate the speed of the cockroach with respect to the floor v_f to the speed of the Lazy Susan at the location of the cockroach:

$$v_f = v - \omega r \qquad (1)$$

Use conservation of angular momentum to obtain:

$$L_{LS} - L_C = 0$$

Express the angular momentum of the Lazy Susan:

$$L_{\mathrm{LS}} = I_{\mathrm{LS}}\omega = \tfrac{1}{2}MR^2\omega$$

Express the angular momentum of the cockroach:

$$L_{\mathrm{C}} = I_{\mathrm{C}}\omega_{\mathrm{C}} = mr^2\left(\frac{v}{r} - \omega\right)$$

Substitute to obtain:

$$\tfrac{1}{2}MR^2\omega - mr^2\left(\frac{v}{r} - \omega\right) = 0$$

Solve for ω to obtain:

$$\omega = \frac{2mrv}{MR^2 + 2mr^2}$$

Substitute in equation (1):

$$v_{\mathrm{f}} = v - \frac{2mr^2 v}{MR^2 + 2mr^2}$$

Substitute numerical values and evaluate v_{f}:

$$v_{\mathrm{f}} = 0.01\,\mathrm{m/s} - \frac{2(0.015\,\mathrm{kg})(0.08\,\mathrm{m})^2(0.01\,\mathrm{m/s})}{(0.25\,\mathrm{m})(0.15\,\mathrm{m})^2 + 2(0.015\,\mathrm{kg})(0.08\,\mathrm{m})^2} = \boxed{9.67\,\mathrm{mm/s}}$$

***58 ••**

Picture the Problem The net external torque acting on this system is zero and so we know that angular momentum is conserved as these disks are brought together. Let the numeral 1 refer to the disk to the left and the numeral 2 to the disk to the right. Let the angular momentum of the disk with the larger radius be positive.

Using conservation of angular momentum, relate the initial angular speeds of the disks to their common final speed and to their moments of inertia:

$$I_{\mathrm{i}}\omega_{\mathrm{i}} = I_{\mathrm{f}}\omega_{\mathrm{f}}$$

or

$$I_1\omega_0 - I_2\omega_0 = (I_1 + I_2)\omega_{\mathrm{f}}$$

Solve for ω_{f}:

$$\omega_{\mathrm{f}} = \frac{I_1 - I_2}{I_1 + I_2}\omega_0$$

Express I_1 and I_2:

$$I_1 = \tfrac{1}{2}m(2r)^2 = 2mr^2$$

and

$$I_2 = \tfrac{1}{2}mr^2$$

Substitute and simplify to obtain:

$$\omega_{\mathrm{f}} = \frac{2mr^2 - \frac{1}{2}mr^2}{2mr^2 + \frac{1}{2}mr^2}\omega_0 = \boxed{\tfrac{3}{5}\omega_0}$$

59 ••

Picture the Problem We can express the angular momentum and kinetic energy of the block directly from their definitions. The tension in the string provides the centripetal force required for the uniform circular motion and can be expressed using Newton's 2nd law. Finally, we can use the work-kinetic energy theorem to express the work required to reduce the radius of the circle by a factor of two.

(*a*) Express the initial angular momentum of the block:

$$L_0 = \boxed{r_0 m v_0}$$

(*b*) Express the initial kinetic energy of the block:

$$K_0 = \boxed{\tfrac{1}{2} m v_0^2}$$

(*c*) Using Newton's 2nd law, relate the tension in the string to the centripetal force required for the circular motion:

$$T = F_c = \boxed{m\frac{v_0^2}{r_0}}$$

Use the work-kinetic energy theorem to relate the required work to the change in the kinetic energy of the block:

$$W = \Delta K = K_f - K_0 = \frac{L_f^2}{2I_f} - \frac{L_0^2}{2I_0}$$
$$= \frac{L_0^2}{2I_f} - \frac{L_0^2}{2I_0} = \frac{L_0^2}{2}\left(\frac{1}{I_f - I_0}\right)$$
$$= \frac{L_0^2}{2}\left(\frac{1}{m\left(\frac{1}{2}r_0\right)^2 - mr_0^2}\right) = -\frac{2}{3}\frac{L_0^2}{mr_0^2}$$

Substitute the result from part (*a*) and simplify to obtain:

$$W = \boxed{-\tfrac{2}{3} m v_0^2}$$

***60** ••

Picture the Problem Because the force exerted by the rubber band is parallel to the position vector of the point mass, the net external torque acting on it is zero and we can use the conservation of angular momentum to determine the speeds of the ball at points *B* and *C*. We'll use mechanical energy conservation to find *b* by relating the kinetic and elastic potential energies at *A* and *B*.

(*a*) Use conservation of momentum to relate the angular momenta at points *A*, *B* and *C*:

$$L_A = L_B = L_C$$

or

$$mv_A r_A = mv_B r_B = mv_C r_C$$

Solve for v_B in terms of v_A:

$$v_B = v_A \frac{r_A}{r_B}$$

Substitute numerical values and evaluate v_B:

$$v_B = (4\,\text{m/s})\frac{0.6\,\text{m}}{1\,\text{m}} = \boxed{2.40\,\text{m/s}}$$

Solve for v_C in terms of v_A:

$$v_C = v_A \frac{r_A}{r_C}$$

Substitute numerical values and evaluate v_C:

$$v_C = (4\,\text{m/s})\frac{0.6\,\text{m}}{0.6\,\text{m}} = \boxed{4.00\,\text{m/s}}$$

(*b*) Use conservation of mechanical energy between points *A* and *B* to relate the kinetic energy of the point mass and the energy stored in the stretched rubber band:

$$E_A = E_B$$

or

$$\tfrac{1}{2}mv_A^2 + \tfrac{1}{2}br_A^2 = \tfrac{1}{2}mv_B^2 + \tfrac{1}{2}br_B^2$$

Solve for b:

$$b = \frac{m\left(v_B^2 - v_A^2\right)}{r_A^2 - r_B^2}$$

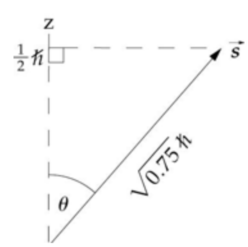
Substitute numerical values and evaluate b:

$$b = \frac{(0.2\,\text{kg})\left[(2.4\,\text{m/s})^2 - (4\,\text{m/s})^2\right]}{(0.6\,\text{m})^2 - (1\,\text{m})^2} = \boxed{3.20\,\text{N/m}}$$

Quantization of Angular Momentum

***61** •

Picture the Problem The electron's spin angular momentum vector is related to its *z* component as shown in the diagram.



Using trigonometry, relate the magnitude of $\vec{s}$ to its z component:

$$\theta = \cos^{-1}\frac{\tfrac{1}{2}\hbar}{\sqrt{0.75}\hbar} = \boxed{54.7°}$$

62 ••

Picture the Problem Equation 10-27*a* describes the quantization of rotational energy. We can show that the energy difference between a given state and the next higher state is proportional to $\ell + 1$ by using Equation 10-27*a* to express the energy difference.

From Equation 10-27*a* we have:

$$K_\ell = \ell(\ell+1)E_{0\mathrm{r}}$$

Using this equation, express the difference between one rotational state and the next higher state:

$$\Delta E = (\ell+1)(\ell+2)E_{0\mathrm{r}} - \ell(\ell+1)E_{0\mathrm{r}}$$
$$= \boxed{2(\ell+1)E_{0\mathrm{r}}}$$

63 ••

Picture the Problem The rotational energies of HBr molecule are related to ℓ and $E_{0\mathrm{r}}$ according to $K_\ell = \ell(\ell+1)E_{0\mathrm{r}}$ where $E_{0\mathrm{r}} = \hbar^2/2I$.

(*a*) Express and evaluate the moment of inertia of the H atom:

$$I = m_\mathrm{p}r^2$$
$$= (1.67\times10^{-27}\ \mathrm{kg})(0.144\times10^{-9}\ \mathrm{m})^2$$
$$= \boxed{3.46\times10^{-47}\ \mathrm{kg\cdot m^2}}$$

(*b*) Relate the rotational energies to ℓ and $E_{0\mathrm{r}}$:

$$K_\ell = \ell(\ell+1)E_{0\mathrm{r}}$$

Evaluate $E_{0\mathrm{r}}$:

$$E_{0\mathrm{r}} = \frac{\hbar^2}{2I} = \frac{(1.05\times10^{-34}\ \mathrm{J\cdot s})^2}{2(3.46\times10^{-47}\ \mathrm{kg\cdot m^2})}$$
$$= 1.59\times10^{-22}\ \mathrm{J}\times\frac{1\,\mathrm{eV}}{1.60\times10^{-19}\ \mathrm{J}}$$
$$= 0.996\,\mathrm{meV}$$

Evaluate E for $\ell = 1$:

$$E_1 = (1+1)(0.996\,\mathrm{meV}) = \boxed{1.99\,\mathrm{meV}}$$

Evaluate E for $\ell = 2$:

$$E_2 = 2(2+1)(0.996\,\mathrm{meV})$$
$$= \boxed{5.98\,\mathrm{meV}}$$

Evaluate E for $\ell = 3$:

$$E_3 = 3(3+1)(0.996\,\mathrm{meV})$$
$$= \boxed{12.0\,\mathrm{meV}}$$

64 ••

Picture the Problem We can use the definition of the moment of inertia of point particles to calculate the rotational inertia of the nitrogen molecule. The rotational energies of nitrogen molecule are related to ℓ and $E_{0\mathrm{r}}$ according to $K_\ell = \ell(\ell+1)E_{0\mathrm{r}}$ where $E_{0\mathrm{r}} = \hbar^2/2I$.

(*a*) Using a rigid dumbbell model, express and evaluate the moment of inertia of the nitrogen molecule about its center of mass:

$$I=\sum_{\text{i}} m_{\text{i}}r_{\text{i}}^2 = m_{\text{N}}r^2+m_{\text{N}}r^2$$
$$=2m_{\text{N}}r^2$$

Substitute numerical values and evaluate *I*:

$$I=2(14)\left(1.66\times10^{-27}\text{ kg}\right)\left(5.5\times10^{-11}\text{ m}\right)^2$$
$$=\boxed{1.41\times10^{-46}\text{ kg}\cdot\text{m}^2}$$

(*b*) Relate the rotational energies to ℓ and $E_{0\text{r}}$:

$$E_\ell=\ell(\ell+1)E_{0\text{r}}$$

Evaluate $E_{0\text{r}}$:

$$E_{0\text{r}}=\frac{\hbar^2}{2I}=\frac{\left(1.05\times10^{-34}\text{ J}\cdot\text{s}\right)^2}{2\left(1.41\times10^{-46}\text{ kg}\cdot\text{m}^2\right)}$$
$$=3.91\times10^{-23}\text{ J}\times\frac{1\text{eV}}{1.60\times10^{-19}\text{ J}}$$
$$=0.244\text{ meV}$$

Substitute to obtain:

$$E_\ell=\boxed{0.244\ell(\ell+1)\text{ meV}}$$

***65 ••**

Picture the Problem We can obtain an expression for the speed of the nitrogen molecule by equating its translational and rotational kinetic energies and solving for *v*. Because this expression includes the moment of inertia *I* of the nitrogen molecule, we can use the definition of the moment of inertia to express *I* for a dumbbell model of the nitrogen molecule. The rotational energies of a nitrogen molecule depend on the quantum number ℓ according to $E_\ell=L^2/2I=\ell(\ell+1)\hbar^2/2I$.

Equate the rotational kinetic energy of the nitrogen molecule in its $\ell=1$ quantum state and its translational kinetic energy:

$$E_1=\tfrac{1}{2}m_{\text{N}}v^2 \qquad (1)$$

Express the rotational energy levels of the nitrogen molecule:

$$E_\ell=\frac{L^2}{2I}=\frac{\ell(\ell+1)\hbar^2}{2I}$$

For $\ell=1$:

$$E_1=\frac{1(1+1)\hbar^2}{2I}=\frac{\hbar^2}{I}$$

Substitute in equation (1):

$$\frac{\hbar^2}{I}=\tfrac{1}{2}m_{\mathrm{N}}v^2$$

Solve for v to obtain:

$$v=\sqrt{\frac{2\hbar^2}{m_{\mathrm{N}}I}} \qquad (2)$$

Using a rigid dumbbell model, express the moment of inertia of the nitrogen molecule about its center of mass:

$$I=\sum_{\mathrm{i}}m_{\mathrm{i}}r_{\mathrm{i}}^2=m_{\mathrm{N}}r^2+m_{\mathrm{N}}r^2=2m_{\mathrm{N}}r^2$$

and

$$m_{\mathrm{N}}I=2m_{\mathrm{N}}^2r^2$$

Substitute in equation (2):

$$v=\sqrt{\frac{2\hbar^2}{2m_{\mathrm{N}}^2r^2}}=\frac{\hbar}{m_{\mathrm{N}}r}$$

Substitute numerical values and evaluate v:

$$v=\frac{1.055\times10^{-34}\ \mathrm{J\cdot s}}{14\left(1.66\times10^{-27}\ \mathrm{kg}\right)\left(5.5\times10^{-11}\ \mathrm{m}\right)}=\boxed{82.5\ \mathrm{m/s}}$$

Collision Problems

66 ••

Picture the Problem Let the zero of gravitational potential energy be at the elevation of the rod. Because the net external torque acting on this system is zero, we know that angular momentum is conserved in the collision. We'll use the definition of angular momentum to express the angular momentum just after the collision and conservation of mechanical energy to determine the speed of the ball just before it makes its perfectly inelastic collision with the rod.

Use conservation of angular momentum to relate the angular momentum before the collision to the angular momentum just after the perfectly inelastic collision:

$$L_{\mathrm{f}}=L_{\mathrm{i}}$$
$$=mvr$$

Use conservation of mechanical energy to relate the kinetic energy of the ball just before impact to its initial potential energy:

$$K_{\mathrm{f}}-K_{\mathrm{i}}+U_{\mathrm{f}}-U_{\mathrm{i}}=0$$

or, because $K_{\mathrm{i}} = U_{\mathrm{f}} = 0$,

$$K_{\mathrm{f}}-U_{\mathrm{i}}=0$$

Letting h represent the distance the

$$v=\sqrt{2gh}$$

ball falls, substitute for K_f and U_i and solve for v to obtain:

Substitute for v to obtain:

$$L_f = mr\sqrt{2gh}$$

Substitute numerical values and evaluate L_f:

$$L_f = (3.2\,\text{kg})(0.9\,\text{m})\sqrt{2(9.81\,\text{m/s}^2)(1.2\,\text{m})}$$
$$= \boxed{14.0\,\text{J}\cdot\text{s}}$$

***67 ••**

Picture the Problem Because there are no external forces or torques acting on the system defined in the problem statement, both linear and angular momentum are conserved in the collision and the velocity of the center of mass after the collision is the same as before the collision. Let the direction the blob of putty is moving initially be the positive x direction and toward the top of the page in the figure be the positive y direction.

Using its definition, express the location of the center of mass relative to the center of the bar:

$$y_{\text{cm}} = \frac{md}{M+m} \text{ below the center of the bar.}$$

Using its definition, express the velocity of the center of mass:

$$v_{\text{cm}} = \boxed{\frac{mv}{M+m}}$$

Using the definition of L in terms of I and ω, express ω:

$$\omega = \frac{L_{\text{cm}}}{I_{\text{cm}}} \qquad (1)$$

Express the angular momentum about the center of mass:

$$L_{\text{cm}} = mv(d - y_{\text{cm}})$$
$$= mv\left(d - \frac{md}{M+m}\right) = \frac{mMvd}{M+m}$$

Using the parallel axis theorem, express the moment of inertia of the system relative to its center of mass:

$$I_{\text{cm}} = \tfrac{1}{12}ML^2 + My_{\text{cm}}^2 + m(d - y_{\text{cm}})^2$$

Substitute for y_{cm} and simplify to obtain:

$$I_{\rm cm} = \tfrac{1}{12}ML^2 + M\left(\frac{md}{M+m}\right)^2 + m\left(d - \frac{md}{M+m}\right)^2$$

$$= \tfrac{1}{12}ML^2 + \frac{Mm^2d^2}{(M+m)^2} + m\left(\frac{d(M+m)-md}{M+m}\right)^2$$

$$= \tfrac{1}{12}ML^2 + \frac{Mm^2d^2}{(M+m)^2} + \frac{mM^2d^2}{(M+m)^2} = \tfrac{1}{12}ML^2 + \frac{(M+m)mMd^2}{(M+m)^2}$$

$$= \tfrac{1}{12}ML^2 + \frac{mMd^2}{M+m}$$

Substitute for $I_{\rm cm}$ and $L_{\rm cm}$ in equation (1) and simplify to obtain:

$$\boxed{\omega = \frac{mMvd}{\frac{1}{12}ML^2(M+m) + Mmd^2}}$$

Remarks: You can verify the expression for $I_{\rm cm}$ by letting $m \to 0$ to obtain $I_{cm} = \frac{1}{12}ML^2$ and letting $M \to 0$ to obtain $I_{\rm cm} = 0$.

68 ••

Picture the Problem Because there are no external forces or torques acting on the system defined in the statement of Problem 67, both linear and angular momentum are conserved in the collision and the velocity of the center of mass after the collision is the same as before the collision. Kinetic energy is also conserved as the collision of the hard sphere with the bar is elastic. Let the direction the sphere is moving initially be the positive x direction and toward the top of the page in the figure be the positive y direction and v' and V' be the final velocities of the objects whose masses are m and M, respectively.

Apply conservation of linear momentum to obtain:

$$p_{\rm i} = p_{\rm f}$$
or
$$mv = mv' + MV' \qquad (1)$$

Apply conservation of angular momentum to obtain:

$$L_{\rm i} = L_{\rm f}$$
or
$$mvd = mv'd + \tfrac{1}{12}ML^2\omega \qquad (2)$$

Set $v' = 0$ in equation (1) and solve for V':

$$V' = \frac{mv}{M} \qquad (3)$$

Use conservation of mechanical energy to relate the kinetic energies of translation and rotation before

$$K_{\rm i} = K_{\rm f}$$
or
$$\tfrac{1}{2}mv^2 = \tfrac{1}{2}MV'^2 + \tfrac{1}{2}\left(\tfrac{1}{12}ML^2\right)\omega^2 \qquad (4)$$

and after the elastic collision:

Substitute (2) and (3) in (4) and simplify to obtain:

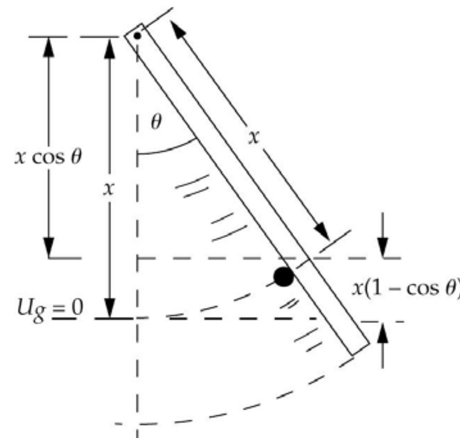
$$1=\frac{m}{M}+\frac{12m}{M}\left(\frac{d^2}{L^2}\right)$$

Solve for d:

$$d=\boxed{L\sqrt{\frac{M-m}{12m}}}$$

69 ••

Picture the Problem Let the zero of gravitational potential energy be a distance *x* below the pivot as shown in the diagram. Because the net external torque acting on the system is zero, angular momentum is conserved in this perfectly inelastic collision. We can also use conservation of mechanical energy to relate the initial kinetic energy of the system after the collision to its potential energy at the top of its swing.



Using conservation of mechanical energy, relate the rotational kinetic energy of the system just after the collision to its gravitational potential energy when it has swung through an angle θ:

$$\Delta K+\Delta U=0$$

or, because $K_f=U_i=0$,

$$-K_i+U_f=0$$

and

$$\tfrac{1}{2}I\omega^2=\left(Mg\frac{d}{2}+mgx\right)(1-\cos\theta)\quad(1)$$

Apply conservation of momentum to the collision:

$$L_i=L_f$$

or

$$0.8dmv=I\omega=\left[\tfrac{1}{3}Md^2+(0.8d)^2m\right]\omega$$

Solve for ω to obtain:

$$\omega=\frac{0.8dmv}{\tfrac{1}{3}Md^2+0.64md^2}\quad(2)$$

Express the moment of inertia of the system about the pivot:

$$I=m(0.8d)^2+\tfrac{1}{3}Md^2$$
$$=0.64md^2+\tfrac{1}{3}Md^2\quad(3)$$

Substitute equations (2) and (3) in equation (1) and simplify to obtain:

$$\left(Mg\frac{d}{2}+mgd\right)(1-\cos\theta)=\frac{0.32(dmv)^2}{\frac{1}{3}Md^2+0.64md^2}$$

Solve for *v*:

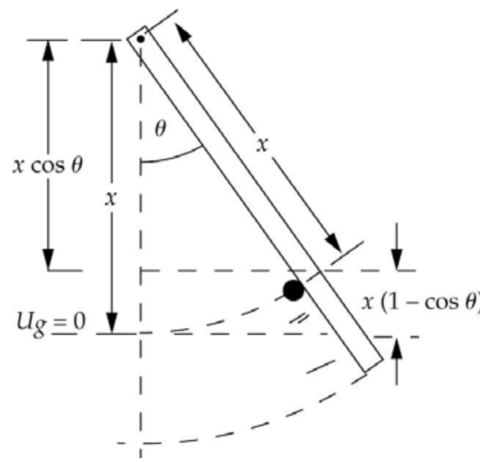
$$v=\sqrt{\frac{(0.5M+0.8m)\left(\frac{1}{3}Md^2+0.64md^2\right)g(1-\cos\theta)}{0.32dm^2}}$$

Evaluate *v* for $\theta = 90°$ to obtain:

$$\boxed{v=\sqrt{\frac{(0.5M+0.8m)\left(\frac{1}{3}Md^2+0.64md^2\right)g}{0.32dm^2}}}$$

70 ••

Picture the Problem Let the zero of gravitational potential energy be a distance *x* below the pivot as shown in the diagram. Because the net external torque acting on the system is zero, angular momentum is conserved in this perfectly inelastic collision. We can also use conservation of mechanical energy to relate the initial kinetic energy of the system after the collision to its potential energy at the top of its swing.



Using conservation of mechanical energy, relate the rotational kinetic energy of the system just after the collision to its gravitational potential energy when it has swung through an angle θ:

$$K_f - K_i + U_f - U_i = 0$$

or, because $K_f = U_i = 0$,

$$-K_i + U_f = 0$$

and

$$\tfrac{1}{2}I\omega^2=\left(Mg\frac{d}{2}+mgx\right)(1-\cos\theta) \quad (1)$$

Apply conservation of momentum to the collision:

$$L_i = L_f$$

or

$$0.8dmv = I\omega = \left[\tfrac{1}{3}Md^2+(0.8d)^2m\right]\omega$$

Solve for ω to obtain:

$$\omega = \frac{0.8dmv}{\frac{1}{2}Md^2 + 0.64md^2} \quad (2)$$

Express the moment of inertia of the system about the pivot:

$$\begin{aligned} I &= m(0.8d)^2 + \tfrac{1}{3}Md^2 \\ &= \left(0.64m + \tfrac{1}{3}M\right)d^2 \\ &= \left[0.64(0.3\,\text{kg}) + \tfrac{1}{3}(0.8\,\text{kg})\right](1.2\,\text{m})^2 \\ &= 0.660\,\text{kg}\cdot\text{m}^2 \end{aligned}$$

Substitute equation (2) in equation (1) and simplify to obtain:

$$\left(Mg\frac{d}{2} + 0.8dmg\right)(1 - \cos\theta) = \frac{0.32(dmv)^2}{I}$$

Solve for v:

$$v = \sqrt{\frac{g(0.5M + 0.8m)(1 - \cos\theta)I}{0.32dm^2}}$$

Substitute numerical values and evaluate v for $\theta = 60°$ to obtain:

$$v = \sqrt{\frac{(9.81\,\text{m/s}^2)\left[0.5(0.8\,\text{kg}) + 0.8(0.3\,\text{kg})\right](0.5)(0.660\,\text{kg}\cdot\text{m}^2)}{0.32(1.2\,\text{m})(0.3\,\text{kg})^2}} = \boxed{7.74\,\text{m/s}}$$

71 ••

Picture the Problem Let the length of the uniform stick be ℓ. We can use the impulse-change in momentum theorem to express the velocity of the center of mass of the stick. By expressing the velocity V of the end of the stick in terms of the velocity of the center of mass and applying the angular impulse-change in angular momentum theorem we can find the angular velocity of the stick and, hence, the velocity of the end of the stick.

(*a*) Apply the impulse-change in momentum theorem to obtain:

$$K = \Delta p = p - p_0 = p$$

or, because $p_0 = 0$ and $p = Mv_{cm}$,

$$K = Mv_{cm}$$

Solve for v_{cm} to obtain:

$$v_{cm} = \boxed{\frac{K}{M}}$$

(*b*) Relate the velocity V of the end of the stick to the velocity of the center of mass v_{cm}:

$$V = v_{cm} + v_{\text{rel to c of m}} = v_{cm} + \omega\left(\tfrac{1}{2}\ell\right) \quad (1)$$

Relate the angular impulse to the change in the angular momentum of the stick:

$$K\left(\tfrac{1}{2}\ell\right) = \Delta L = L - L_0 = I_{cm}\omega$$

or, because $L_0 = 0$,

$$K\left(\tfrac{1}{2}\ell\right) = I_{cm}\omega$$

Refer to Table 9-1 to find the moment of inertia of the stick with respect to its center of mass:

$$I_{cm} = \tfrac{1}{12}M\ell^2$$

Substitute to obtain:

$$K\left(\tfrac{1}{2}\ell\right) = \tfrac{1}{12}M\ell^2\omega$$

Solve for ω:

$$\omega = \frac{6K}{M\ell}$$

Substitute in equation (1) to obtain:

$$V = \frac{K}{M} + \left(\frac{6K}{M\ell}\right)\frac{\ell}{2} = \boxed{\frac{4K}{M}}$$

(*c*) Relate the velocity V' of the other end of the stick to the velocity of the center of mass v_{cm}:

$$V = v_{cm} - v_{\text{rel to c of m}} = v_{cm} - \omega\left(\tfrac{1}{2}\ell\right)$$
$$= \frac{K}{M} - \left(\frac{6K}{M\ell}\right)\frac{\ell}{2} = \boxed{-\frac{2K}{M}}$$

(*d*) Letting x be the distance from the center of mass toward the end not struck, express the condition that the point at x is at rest:

$$v_{cm} - \omega x = 0$$

Solve for x to obtain:

$$\frac{K}{M} - \frac{6K}{M\ell}x = 0$$

Solve for x to obtain:

$$x = \frac{\frac{K}{M}}{\frac{6K}{M\ell}} = \boxed{\tfrac{1}{6}\ell}$$

Note that for a meter stick struck at the 100-cm mark, the stationary point would be at the 33.3-cm mark.

Remarks: You can easily check this result by placing a meterstick on the floor and giving it a sharp blow at the 100-cm mark.

72 ••

Picture the Problem Because the net external torque acting on the system is zero, angular momentum is conserved in this perfectly inelastic collision.

(*a*) Use its definition to express the total angular momentum of the disk and projectile just before impact:

$$L_0 = \boxed{m_p v_0 b}$$

(*b*) Use conservation of angular momentum to relate the angular momenta just before and just after the collision:

$$L_0 = L = I\omega \text{ and } \omega = \frac{L_0}{I}$$

Express the moment of inertia of the disk + projectile:

$$I = \tfrac{1}{2}MR^2 + m_p b^2$$

Substitute for I in the expression for ω to obtain:

$$\omega = \boxed{\frac{2m_p v_0 b}{MR^2 + 2m_p b^2}}$$

(*c*) Express the kinetic energy of the system after impact in terms of its angular momentum:

$$K_f = \frac{L^2}{2I} = \frac{(m_p v_0 b)^2}{2\left(\frac{1}{2}MR^2 + m_p b^2\right)}$$

$$= \boxed{\frac{(m_p v_0 b)^2}{MR^2 + 2m_p b^2}}$$

(*d*) Express the difference between the initial and final kinetic energies, substitute, and simplify to obtain:

$$\Delta E = K_i - K_f$$

$$= \tfrac{1}{2}m_p v_0^2 - \frac{(m_p v_0 b)^2}{MR^2 + 2m_p b^2}$$

$$= \boxed{\tfrac{1}{2}m_p v_0^2\left(1 - \frac{m_p b^2}{MR^2 + 2m_p b^2}\right)}$$

***73 ••**

Picture the Problem Because the net external torque acting on the system is zero, angular momentum is conserved in this perfectly inelastic collision. The rod, on its downward swing, acquires rotational kinetic energy. Angular momentum is conserved in the perfectly inelastic collision with the particle and the rotational kinetic of the after-collision system is then transformed into gravitational potential energy as the rod-plus-particle swing upward. Let the zero of gravitational potential energy be at a distance L_1 below the pivot and use both angular momentum and mechanical energy conservation to relate the distances L_1 and L_2 and the masses M and m.

Use conservation of energy to relate the initial and final potential energy of the rod to its rotational kinetic energy just before it collides with the particle:

$$K_f - K_i + U_f - U_i = 0$$

or, because $K_i = 0$,

$$K_f + U_f - U_i = 0$$

Substitute for K_f, U_f, and U_i to obtain:

$$\tfrac{1}{2}\left(\tfrac{1}{3}ML_1^2\right)\omega^2 + Mg\frac{L_1}{2} - MgL_1 = 0$$

Solve for ω:

$$\omega = \sqrt{\frac{3g}{L_1}}$$

Letting ω' represent the angular speed of the rod-and-particle system just after impact, use conservation of angular momentum to relate the angular momenta before and after the collision:

$$L_i = L_f$$

or

$$\left(\tfrac{1}{3}ML_1^2\right)\omega = \left(\tfrac{1}{3}ML_1^2 + mL_2^2\right)\omega'$$

Solve for ω':

$$\omega' = \frac{\tfrac{1}{3}ML_1^2}{\tfrac{1}{3}ML_1^2 + mL_2^2}\omega$$

Use conservation of energy to relate the rotational kinetic energy of the rod-plus-particle just after their collision to their potential energy when they have swung through an angle θ_{max}:

$$K_f - K_i + U_f - U_i = 0$$

or, because $K_f = 0$,

$$-\tfrac{1}{2}I\omega'^2 + Mg\left(\tfrac{1}{2}L_1\right)\left(1-\cos\theta_{max}\right) + mgL_2\left(1-\cos\theta_{max}\right) = 0 \qquad (1)$$

Express the moment of inertia of the system with respect to the pivot:

$$I = \tfrac{1}{3}ML_1^2 + mL_2^2$$

Substitute for θ_{max}, I and ω' in equation (1):

$$\frac{3\frac{g}{L_1}\left(\tfrac{1}{3}ML_1^2\right)^2}{\tfrac{1}{3}ML_1^2 + mL_2^2} = Mg\left(\tfrac{1}{2}L_1\right) + mgL_2$$

Simplify to obtain:

$$L_1^3 = 2\frac{m}{M}L_1^2L_2 + 3L_2^2L_1 + 6\frac{m}{M}L_2^3 \qquad (2)$$

Simplify equation (2) by letting $\alpha = m/M$ and $\beta = L_2/L_1$ to obtain:

$$6\alpha^2\beta^3 + 3\beta^2 + 2\alpha\beta - 1 = 0$$

Substitute for α and simplify to obtain the cubic equation in β:

$$12\beta^3 + 9\beta^2 + 4\beta - 3 = 0$$

Use the solver function* of your calculator to find the only real value

$$\beta = \boxed{0.349}$$

of β:

***Remarks**: **Most graphing calculators have a ″solver″ feature. One can solve the cubic equation using either the ″graph″ and ″trace″ capabilities or the ″solver″ feature. The root given above was found using SOLVER on a TI-85.**

74 ••

Picture the Problem Because the net external torque acting on the system is zero, angular momentum is conserved in this perfectly inelastic collision. The rod, on its downward swing, acquires rotational kinetic energy. Angular momentum is conserved in the perfectly inelastic collision with the particle and the rotational kinetic energy of the after-collision system is then transformed into gravitational potential energy as the rod-plus-particle swing upward. Let the zero of gravitational potential energy be at a distance L_1 below the pivot and use both angular momentum and mechanical energy conservation to relate the distances L_1 and L_2 and the mass M to m.

(*a*) Use conservation of energy to relate the initial and final potential energy of the rod to its rotational kinetic energy just before it collides with the particle:

$$K_f - K_i + U_f - U_i = 0$$

or, because $K_i = 0$,

$$K_f + U_f - U_i = 0$$

Substitute for K_f, U_f, and U_i to obtain:

$$\tfrac{1}{2}\left(\tfrac{1}{3}ML_1^2\right)\omega^2 + Mg\frac{L_1}{2} - MgL_1 = 0$$

Solve for ω:

$$\omega = \sqrt{\frac{3g}{L_1}}$$

Letting ω' represent the angular speed of the system after impact, use conservation of angular momentum to relate the angular momenta before and after the collision:

$$L_i = L_f$$

or

$$\left(\tfrac{1}{3}ML_1^2\right)\omega = \left(\tfrac{1}{3}ML_1^2 + mL_2^2\right)\omega' \qquad (1)$$

Solve for ω':

$$\omega' = \frac{\tfrac{1}{3}ML_1^2}{\tfrac{1}{3}ML_1^2 + mL_2^2}\,\omega = \frac{\tfrac{1}{3}ML_1^2}{\tfrac{1}{3}ML_1^2 + mL_2^2}\sqrt{\frac{3g}{L_1}}$$

Substitute numerical values to obtain:

$$\omega' = \frac{\frac{1}{3}(2\,\text{kg})(1.2\,\text{m})^2}{\frac{1}{3}(2\,\text{kg})(1.2\,\text{m})^2 + m(0.8\,\text{m})^2} \times \sqrt{\frac{3(9.81\,\text{m/s}^2)}{1.2\,\text{m}}}$$
$$= \frac{4.75\,\text{kg}\cdot\text{m}^2/\text{s}}{0.960\,\text{kg}\cdot\text{m}^2 + (0.64\,\text{m}^2)m}$$
$$= \frac{4.75\,\text{kg/s}}{0.960\,\text{kg} + 0.64m}$$

Use conservation of energy to relate the rotational kinetic energy of the rod-plus-particle just after their collision to their potential energy when they have swung through an angle θ_{max}:

$$K_f - K_i + U_f - U_i = 0$$

or, because $K_f = 0$,

$$-K_i + U_f - U_i = 0$$

Substitute for K_i, U_f, and U_i to obtain:

$$-\tfrac{1}{2}I\omega'^2 + Mg\left(\tfrac{1}{2}L_1\right)(1-\cos\theta_{max}) + mgL_2(1-\cos\theta_{max}) = 0$$

Express the moment of inertia of the system with respect to the pivot:

$$I = \tfrac{1}{3}ML_1^2 + mL_2^2$$

Substitute for θ_{max}, I and ω' in equation (1) and simplify to obtain:

$$\frac{\frac{1}{2}(4.75\,\text{kg/s})^2}{0.960\,\text{kg} + 0.64m} = 0.2g(ML_1 + mL_2)$$

Substitute for M, L_1 and L_2 and simplify to obtain:

$$m^2 + 3.00m - 8.901 = 0$$

Solve the quadratic equation for its positive root:

$$m = \boxed{1.84\,\text{kg}}$$

(*b*) The energy dissipated in the inelastic collision is:

$$\Delta E = U_i - U_f \qquad (2)$$

Express U_i:

$$U_i = Mg\frac{L_1}{2}$$

Express U_f:

$$U_f = (1-\cos\theta_{max})g\left(M\frac{L_1}{2} + mL_2\right)$$

Substitute in equation (2) to obtain:

$$\Delta E = Mg\frac{L_1}{2} - (1-\cos\theta_{max})g\left(M\frac{L_1}{2} + mL_2\right)$$

Substitute numerical values and evaluate ΔE:

$$U_f = \frac{(2\,\text{kg})(9.81\,\text{m/s}^2)(1.2\,\text{m})}{2} - (1-\cos37°)(9.81\,\text{m/s}^2)\left(\frac{(2\,\text{kg})(1.2\,\text{m})}{2} + (1.85\,\text{kg})(0.8\,\text{m})\right) = \boxed{6.51\,\text{J}}$$

75 ••

Picture the Problem Let ω_i and ω_f be the angular velocities of the rod immediately before and immediately after the inelastic collision with the mass m. Let ω_0 be the initial angular velocity of the rod. Choose the zero of gravitational potential energy be at a distance L_1 below the pivot. We apply energy conservation to determine ω_f and conservation of angular momentum to determine ω_i. We'll apply energy conservation to determine ω_0. Finally, we'll find the energies of the system immediately before and after the collision and the energy dissipated.

Express the energy dissipated in the inelastic collision:

$$\Delta E = U_i - U_f \quad (1)$$

Use energy conservation to relate the kinetic energy of the system immediately after the collision to its potential energy after a 180° rotation:

$$K_f - K_i + U_f - U_i = 0$$

or, because $K_f = K_{top} = 0$ and $K_i = K_{bottom}$,

$$-K_{bottom} + U_{top} - U_{bottom} = 0$$

Substitute for K_{bottom}, U_{top}, and U_{bottom} to obtain:

$$-\tfrac{1}{2}I\omega_f^2 + \tfrac{3}{2}MgL_1 + mg(L_1 + L_2) - \tfrac{1}{2}MgL_1 - mg(L_1 - L_2) = 0$$

Simplify to obtain:

$$-\tfrac{1}{2}I\omega_f^2 + MgL_1 + 2mgL_2 = 0 \quad (2)$$

Express I:

$$I = \tfrac{1}{3}ML_1^2 + mL_2^2$$

Substitute for I in equation (2) and solve for ω_f to obtain:

$$\omega_f = \sqrt{\frac{2g(ML_1 + 2mL_2)}{\tfrac{1}{3}ML_1^2 + mL_2^2}}$$

Substitute numerical values and evaluate ω_f:

$$\omega_f = \sqrt{\frac{2(9.81\,\text{m/s}^2)[(0.75\,\text{kg})(1.2\,\text{m}) + 2(0.4\,\text{kg})(0.8\,\text{m})]}{\frac{1}{3}(0.75\,\text{kg})(1.2\,\text{m})^2 + (0.4\,\text{kg})(0.8\,\text{m})^2}} = 7.00\,\text{rad/s}$$

Use conservation of angular momentum to relate the angular momentum of the system just before the collision to its angular momentum just after the collision:

$$L_i = L_f$$

or

$$I_i\omega_i = I_f\omega_f$$

Substitute for I_i and I_f and solve for ω_i:

$$\left(\tfrac{1}{3}ML_1^2\right)\omega_i = \left(\tfrac{1}{3}ML_1^2 + mL_2^2\right)\omega_f$$

and

$$\omega_i = \left[1 + \frac{3m}{M}\left(\frac{L_2}{L_1}\right)^2\right]\omega_f$$

Substitute numerical values and evaluate ω_i:

$$\omega_i = \left[1 + \frac{3(0.4\,\text{kg})}{0.75\,\text{kg}}\left(\frac{0.8\,\text{m}}{1.2\,\text{m}}\right)^2\right](7.00\,\text{rad/s})$$
$$= 12.0\,\text{rad/s}$$

Apply conservation of mechanical energy to relate the initial rotational kinetic energy of the rod to its rotational kinetic energy just before its collision with the particle:

$$K_f - K_i + U_f - U_i = 0$$

Substitute to obtain:

$$\tfrac{1}{2}\left(\tfrac{1}{3}ML_1^2\right)\omega_i^2 - \tfrac{1}{2}\left(\tfrac{1}{3}ML_1^2\right)\omega_0^2 + Mg\frac{L_1}{2} - MgL_1 = 0$$

Solve for ω_0:

$$\omega_0 = \sqrt{\omega_i^2 - \frac{3g}{L_1}}$$

Substitute numerical values and evaluate ω_0:

$$\omega_0 = \sqrt{(12\,\text{rad/s})^2 - \frac{3(9.81\,\text{m/s}^2)}{1.2\,\text{m}}}$$
$$= \boxed{10.9\,\text{rad/s}}$$

Substitute in equation (1) to express the energy dissipated in the collision:

$$\Delta E = \tfrac{1}{2}\left(\tfrac{1}{3}ML_1^2\right)\omega_i^2 - MgL_1 + 2mgL_2$$

Substitute numerical values and evaluate ΔE:

$$\Delta E = \tfrac{1}{6}(0.75\,\text{kg})(1.2\,\text{m})^2(12\,\text{rad/s})^2 - \left(9.81\,\text{m/s}^2\right)[(0.75\,\text{kg})(1.2\,\text{m}) + 2(0.4\,\text{kg})(0.8\,\text{m})]$$
$$= \boxed{10.8\,\text{J}}$$

76 •••

Picture the Problem Let v be the speed of the particle immediately after the collision and ω_i and ω_f be the angular velocities of the rod immediately before and immediately after the elastic collision with the mass m. Choose the zero of gravitational potential energy be at a distance L_1 below the pivot. Because the net external torque acting on the system is zero, angular momentum is conserved in this elastic collision. The rod, on its downward swing, acquires rotational kinetic energy. Angular momentum is conserved in the elastic collision with the particle and the kinetic energy of the after-collision system is then transformed into gravitational potential energy as the rod-plus-particle swing upward. Let the zero of gravitational potential energy be at a distance L_1 below the pivot and use both angular momentum and mechanical energy conservation to relate the distances L_1 and L_2 and the mass M to m.

Use energy conservation to relate the energies of the system immediately before and after the elastic collision:

$$K_f - K_i + U_f - U_i = 0$$

or, because $K_i = 0$,

$$K_f + U_f - U_i = 0$$

Substitute for K_f, U_f, and U_i to obtain:

$$\tfrac{1}{2}mv^2 + Mg\frac{L_1}{2}\left(1 - \cos\theta_{max}\right) - Mg\frac{L_1}{2} = 0$$

Solve for mv^2:

$$mv^2 = MgL_1\cos\theta_{max} \qquad (1)$$

Apply conservation of energy to express the angular speed of the rod just before the collision:

$$K_f - K_i + U_f - U_i = 0$$

or, because $K_i = 0$,

$$K_f + U_f - U_i = 0$$

Substitute for K_f, U_f, and U_i to obtain:

$$\tfrac{1}{2}\left(\tfrac{1}{3}ML_1^2\right)\omega_i^2 + Mg\frac{L_1}{2} - MgL_1 = 0$$

Solve for ω_i:

$$\omega_i = \sqrt{\frac{3g}{L_1}}$$

Apply conservation of energy to the rod after the collision:

$$\tfrac{1}{2}\left(\tfrac{1}{3}ML_1^2\right)\omega_f^2 - Mg\frac{L_1}{2}\left(1-\cos\theta_{max}\right)=0$$

Solve for ω_f:

$$\omega_f = \sqrt{\frac{0.6g}{L_1}}$$

Apply conservation of angular momentum to the collision:

$$L_i = L_f$$

or

$$\left(\tfrac{1}{3}ML_1^2\right)\omega_i = \left(\tfrac{1}{3}ML_1^2\right)\omega_f + mvL_2$$

Solve for mv:

$$mv = \frac{\tfrac{1}{3}ML_1^2\left(\omega_i-\omega_f\right)}{L_2}$$

Substitute for ω_f and ω_I to obtain:

$$mv = \frac{ML_1^2\left(\sqrt{\frac{3g}{L_1}}-\sqrt{\frac{0.6g}{L_1}}\right)}{3L_2} \quad (2)$$

Divide equation (1) by equation (2) to eliminate m and solve for v:

$$v = \frac{MgL_1\cos\theta_{max}}{\frac{ML_1^2\left(\sqrt{\frac{3g}{L_1}}-\sqrt{\frac{0.6g}{L_1}}\right)}{3L_2}} = \frac{3gL_2\cos\theta_{max}}{\sqrt{3gL_1}-\sqrt{0.6gL_1}}$$

Substitute numerical values and evaluate v:

$$v = \frac{3\left(9.81\,\text{m/s}^2\right)\left(0.8\,\text{m}\right)\cos 37°}{\sqrt{3\left(9.81\,\text{m/s}^2\right)\left(1.2\,\text{m}\right)}-\sqrt{0.6\left(9.81\,\text{m/s}^2\right)\left(1.2\,\text{m}\right)}} = 5.72\,\text{m/s}$$

Solve equation (1) for m:

$$m = \frac{MgL_1\cos\theta_{max}}{v^2}$$

Substitute for v in the expression for mv and solve for m:

$$m = \frac{\left(2\,\text{kg}\right)\left(9.81\,\text{m/s}^2\right)\left(1.2\,\text{m}\right)\cos 37°}{\left(5.72\,\text{m/s}\right)^2} = \boxed{0.575\,\text{kg}}$$

Because the collision was elastic:

$$\Delta E = \boxed{0}$$

77 ••

Picture the Problem We can determine the angular momentum of the wheel and the angular velocity of its precession from their definitions. The period of the precessional motion can be found from its angular velocity and the angular momentum associated with the motion of the center of mass from its definition.

(*a*) Using the definition of angular momentum, express the angular momentum of the spinning wheel:

$$L = I\omega = MR^2\omega = \frac{w}{g}R^2\omega$$

Substitute numerical values and evaluate *L*:

$$L = \left(\frac{30\,\text{N}}{9.81\,\text{m/s}^2}\right)(0.28\,\text{m})^2 \times\left(12\frac{\text{rev}}{\text{s}}\times\frac{2\pi\,\text{rad}}{\text{rev}}\right) = \boxed{18.1\ \text{J}\cdot\text{s}}$$

(*b*) Using its definition, express the angular velocity of precession:

$$\omega_{\text{p}} = \frac{d\phi}{dt} = \frac{MgD}{L}$$

Substitute numerical values and evaluate ω_{p}:

$$\omega_{\text{p}} = \frac{(30\,\text{N})(0.25\,\text{m})}{18.1\,\text{J}\cdot\text{s}} = \boxed{0.414\,\text{rad/s}}$$

(*c*) Express the period of the precessional motion as a function of the angular velocity of precession:

$$T = \frac{2\pi}{\omega_{\text{p}}} = \frac{2\pi}{0.414\,\text{rad/s}} = \boxed{15.2\,\text{s}}$$

(*d*) Express the angular momentum of the center of mass due to the precession:

$$L_{\text{p}} = I_{\text{cm}}\omega_{\text{p}} = MD^2\omega_{\text{p}}$$

Substitute numerical values and evaluate L_{p}:

$$L_{\text{p}} = \left(\frac{30\,\text{N}}{9.81\,\text{m/s}^2}\right)(0.25\,\text{m})^2(0.414\,\text{rad/s}) = \boxed{0.0791\,\text{J}\cdot\text{s}}$$

The direction of L_{p} is either up or down, depending on the direction of *L*.

***78** ••

Picture the Problem The angular velocity of precession can be found from its definition. Both the speed and acceleration of the center of mass during precession are related to the angular velocity of precession. We can use Newton's 2nd law to find the vertical and horizontal components of the force exerted by the pivot.

(*a*) Using its definition, express the angular velocity of precession:

$$\omega_p = \frac{d\phi}{dt} = \frac{MgD}{I_s\omega_s} = \frac{MgD}{\frac{1}{2}MR^2\omega_s} = \frac{2gD}{R^2\omega_s}$$

Substitute numerical values and evaluate ω_p:

$$\omega_p = \frac{2(9.81\,\text{m/s}^2)(0.05\,\text{m})}{(0.064\,\text{m})^2\left(700\frac{\text{rev}}{\text{min}}\times\frac{2\pi\,\text{rad}}{\text{rev}}\times\frac{1\,\text{min}}{60\,\text{s}}\right)} = \boxed{3.27\,\text{rad/s}}$$

(*b*) Express the speed of the center of mass in terms of its angular velocity of precession:

$$v_{cm} = D\omega_p = (0.05\,\text{m})(3.27\,\text{rad/s}) = \boxed{0.164\,\text{m/s}}$$

(*c*) Relate the acceleration of the center of mass to its angular velocity of precession:

$$a_{cm} = D\omega_p^2 = (0.05\,\text{m})(3.27\,\text{rad/s})^2 = \boxed{0.535\,\text{m/s}^2}$$

(*d*) Use Newton's 2nd law to relate the vertical component of the force exerted by the pivot to the weight of the disk:

$$F_v = Mg = (2.5\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{24.5\,\text{N}}$$

Relate the horizontal component of the force exerted by the pivot to the acceleration of the center of mass:

$$F_v = Ma_{cm} = (2.5\,\text{kg})(0.535\,\text{m/s}^2) = \boxed{1.34\,\text{N}}$$

General Problems

79 •

Picture the Problem While the 3-kg particle is moving in a straight line, it has angular momentum given by $\vec{L} = \vec{r}\times\vec{p}$ where $\vec{r}$ is its position vector and $\vec{p}$ is its linear momentum. The torque due to the applied force is given by $\vec{\tau} = \vec{r}\times\vec{F}$.

(*a*) Express the angular momentum of the particle:

$$\vec{L} = \vec{r}\times\vec{p}$$

Express the vectors $\vec{r}$ and $\vec{p}$:

$$\vec{r} = (12\,\text{m})\hat{i} + (5.3\,\text{m})\hat{j}$$

and

$$\vec{p} = mv\hat{i} = (3\,\text{kg})(3\,\text{m/s})\hat{i} = (9\,\text{kg}\cdot\text{m/s})\hat{i}$$

Substitute and simplify to find $\vec{L}$:

$$\vec{L} = [(12\,\text{m})\hat{i} + (5.3\,\text{m})\hat{j}] \times (9\,\text{kg}\cdot\text{m/s})\hat{i} = (47.7\,\text{kg}\cdot\text{m}^2/\text{s})(\hat{j}\times\hat{i}) = \boxed{-(47.7\,\text{kg}\cdot\text{m}^2/\text{s})\hat{k}}$$

(*b*) Using its definition, express the torque due to the force:

$$\vec{\tau} = \vec{r} \times \vec{F}$$

Substitute and simplify to find $\vec{\tau}$:

$$\vec{\tau} = [(12\,\text{m})\hat{i} + (5.3\,\text{m})\hat{j}] \times (-3\,\text{N})\hat{i} = -(15.9\,\text{N}\cdot\text{m})(\hat{j}\times\hat{i}) = \boxed{(15.9\,\text{N}\cdot\text{m})\hat{k}}$$

80 •

Picture the Problem The angular momentum of the particle is given by $\vec{L} = \vec{r} \times \vec{p}$ where $\vec{r}$ is its position vector and $\vec{p}$ is its linear momentum. The torque acting on the particle is given by $\vec{\tau} = d\vec{L}/dt$.

Express the angular momentum of the particle:

$$\vec{L} = \vec{r} \times \vec{p} = \vec{r} \times m\vec{v} = m\vec{r} \times \vec{v} = m\vec{r} \times \frac{d\vec{r}}{dt}$$

Evaluate $\frac{d\vec{r}}{dt}$:

$$\frac{d\vec{r}}{dt} = 6t\hat{j}$$

Substitute and simplify to find $\vec{L}$:

$$\vec{L} = [(3\,\text{kg})\{(4\,\text{m})\hat{i} + (3t^2\,\text{m/s}^2)\hat{j}\}] \times (6t\,\text{m/s})\hat{j} = \boxed{(72.0t\,\text{J}\cdot\text{s})\hat{k}}$$

Find the torque due to the force:

$$\vec{\tau} = \frac{d\vec{L}}{dt} = \frac{d}{dt}[(72.0t\,\text{J}\cdot\text{s})\hat{k}] = \boxed{(72.0\,\text{N}\cdot\text{m})\hat{k}}$$

81 ••

Picture the Problem The ice skaters rotate about their center of mass; a point we can locate using its definition. Knowing the location of the center of mass we can determine their moment of inertia with respect to an axis through this point. The angular momentum of the system is then given by $L = I_{cm}\omega$ and its kinetic energy can be found from $K = L^2/2I_{cm}$.

(*a*) Express the angular momentum of the system about the center of mass of the skaters:

$$L = I_{cm}\omega$$

Using its definition, locate the center of mass, relative to the 85-kg skater, of the system:

$$x_{cm} = \frac{(55\,\text{kg})(1.7\,\text{m}) + (85\,\text{kg})(0)}{55\,\text{kg} + 85\,\text{kg}} = 0.668\,\text{m}$$

Calculate I_{cm}:

$$I_{cm} = (55\,\text{kg})(1.7\,\text{m} - 0.668\,\text{m})^2 + (85\,\text{kg})(0.668\,\text{m})^2 = 96.5\,\text{kg}\cdot\text{m}^2$$

Substitute to determine *L*:

$$L = \left(96.5\,\text{kg}\cdot\text{m}^2\right)\left(\frac{1\,\text{rev}}{2.5\,\text{s}} \times \frac{2\pi\,\text{rad}}{\text{rev}}\right) = \boxed{243\,\text{J}\cdot\text{s}}$$

(*b*) Relate the total kinetic energy of the system to its angular momentum and evaluate *K*:

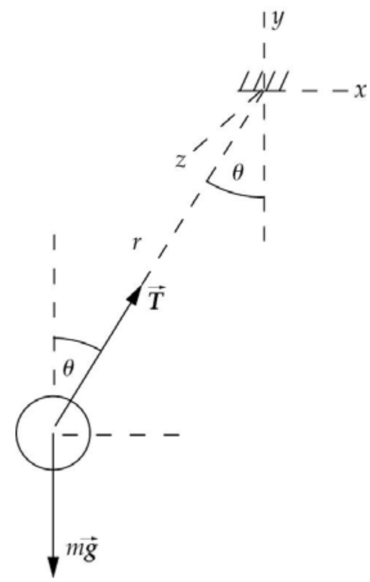
$$K = \frac{L^2}{2I_{cm}}$$

Substitute numerical values and evaluate *K*:

$$K = \frac{(243\,\text{J}\cdot\text{s})^2}{2\left(96.5\,\text{kg}\cdot\text{m}^2\right)} = \boxed{306\,\text{J}}$$

***82** ••

Picture the Problem Let the origin of the coordinate system be at the pivot (point *P*). The diagram shows the forces acting on the ball. We'll apply Newton's 2nd law to the ball to determine its speed. We'll then use the derivative of its position vector to express its velocity and the definition of angular momentum to show that $\vec{L}$ has both horizontal and vertical components. We can use the derivative of $\vec{L}$ with respect to time to show that the rate at which the angular momentum of the ball changes is equal to the torque, relative to the pivot point, acting on it.



(*a*) Express the angular momentum of the ball about the point of support:

$$\vec{L} = \vec{r} \times \vec{p} = m\vec{r} \times \vec{v} \qquad (1)$$

Apply Newton's 2nd law to the ball:

$$\sum F_x = T\sin\theta = m\frac{v^2}{r\sin\theta}$$

and

$$\sum F_z = T\cos\theta - mg = 0$$

Eliminate *T* between these equations and solve for *v*:

$$v = \sqrt{rg\sin\theta\tan\theta}$$

Substitute numerical values and evaluate *v*:

$$v = \sqrt{(1.5\,\text{m})(9.81\,\text{m/s}^2)\sin 30°\tan 30°} = 2.06\,\text{m/s}$$

Express the position vector of the ball:

$$\vec{r} = (1.5\,\text{m})\sin 30°(\cos\omega t\,\hat{i} + \sin\omega t\hat{j}) - (1.5\,\text{m})\cos 30°\hat{k}$$

where $\omega = \omega\hat{k}$.

Find the velocity of the ball:

$$\vec{v} = \frac{d\vec{r}}{dt} = (0.75\omega\,\text{m/s})(-\sin\omega t\,\hat{i} + \cos\omega t\,\hat{j})$$

Evaluate ω:

$$\omega = \frac{2.06\,\text{m/s}}{(1.5\,\text{m})\sin 30°} = 2.75\,\text{rad/s}$$

Substitute for ω to obtain: $\vec{v} = (2.06\,\text{m/s})\left(-\sin\omega t\,\hat{\boldsymbol{i}} + \cos\omega t\hat{\boldsymbol{j}}\right)$

Substitute in equation (1) and evaluate $\vec{L}$:

$$\begin{aligned}\vec{L} &= (2\,\text{kg})\left[(1.5\,\text{m})\sin 30°\left(\cos\omega t\,\hat{\boldsymbol{i}} + \sin\omega t\,\hat{\boldsymbol{j}}\right) - (1.5\,\text{m})\cos 30°\hat{\boldsymbol{k}}\right] \\ &\quad \times\left[(2.06\,\text{m/s})\left(-\sin\omega t\,\hat{\boldsymbol{i}} + \cos\omega t\,\hat{\boldsymbol{j}}\right)\right] \\ &= \left[5.36\left(\cos\omega t\,\hat{\boldsymbol{i}} + \sin\omega t\,\hat{\boldsymbol{j}}\right) + 3.09\,\hat{\boldsymbol{k}}\right]\text{J}\cdot\text{s}\end{aligned}$$

The horizontal component of $\vec{L}$ is: $\boxed{5.36\left(\cos\omega t\,\hat{\boldsymbol{i}} + \sin\omega t\,\hat{\boldsymbol{j}}\right)\text{J}\cdot\text{s}}$

The vertical component of $\vec{L}$ is: $\boxed{3.09\,\hat{\boldsymbol{k}}\,\text{J}\cdot\text{s}}$

(*b*) Evaluate $\dfrac{d\vec{L}}{dt}$: $\dfrac{d\vec{L}}{dt} = \left[5.36\omega\left(-\sin\omega t\,\hat{\boldsymbol{i}} + \cos\omega t\hat{\boldsymbol{j}}\right)\right]\text{J}$

Evaluate the magnitude of $\dfrac{d\vec{L}}{dt}$:

$$\begin{aligned}\left|\frac{d\vec{L}}{dt}\right| &= (5.36\,\text{N}\cdot\text{m}\cdot\text{s})(2.75\,\text{rad/s}) \\ &= \boxed{14.7\,\text{N}\cdot\text{m}}\end{aligned}$$

Express the magnitude of the torque exerted by gravity about the point of support: $\tau = mgr\sin\theta$

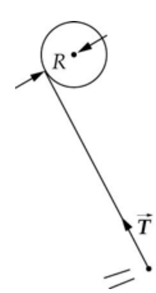
Substitute numerical values and evaluate τ:

$$\begin{aligned}\tau &= (2\,\text{kg})\left(9.81\,\text{m/s}^2\right)(1.5\,\text{m})\sin 30° \\ &= \boxed{14.7\,\text{N}\cdot\text{m}}\end{aligned}$$

83 ••

Picture the Problem In part (*a*) we need to decide whether a net torque acts on the object. In part (*b*) the issue is whether any external forces act on the object. In part (*c*) we can apply the definition of kinetic energy to find the speed of the object when the unwrapped length has shortened to *r*/2.

(*a*) Consider the overhead view of the cylindrical post and the object shown in the adjoining figure. The object rotates counterclockwise. The torque about the center of the cylinder is clockwise and of magnitude *RT*, where *R* is the radius of the cylinder and *T* is the tension. So



L must decrease. $\boxed{\text{No, } L \text{ decreases.}}$

(*b*) Because, in this frictionless environment, no net external forces act on the object: $\boxed{\text{Its kinetic energy is constant.}}$

(*c*) Express the kinetic energy of the object as it spirals inward:

$$K = \tfrac{1}{2}I\omega^2 = \tfrac{1}{2}\left(mr^2\right)\frac{v^2}{r^2} = \tfrac{1}{2}mv^2$$

$\boxed{v_0\text{. (The kinetic energy remains constant.)}}$

84 ••

Picture the Problem Because the net torque acting on the system is zero; we can use conservation of angular momentum to relate the initial and final angular velocities of the system.

Using conservation of angular momentum, relate the initial and final angular velocities to the initial and final moments of inertia:

$$L_i = L_f$$

or

$$I_i\omega_i = I_f\omega_f$$

Solve for ω_i:

$$\omega_f = \frac{I_i}{I_f}\omega_i = \frac{I_i}{I_f}\omega$$

Express I_i:

$$I_i = \tfrac{1}{10}ML^2 + 2\left(\tfrac{1}{4}m\ell^2\right)$$

Express I_f:

$$I_f = \tfrac{1}{10}ML^2 + 2\left(\tfrac{1}{4}mL^2\right)$$

Substitute to express ω_f in terms of ω:

$$\omega_f = \frac{\tfrac{1}{10}ML^2 + 2\left(\tfrac{1}{4}m\ell^2\right)}{\tfrac{1}{10}ML^2 + 2\left(\tfrac{1}{4}mL^2\right)}\omega = \boxed{\frac{M + 5m\dfrac{\ell^2}{L^2}}{M + 5m}\omega}$$

Express the initial kinetic energy of the system:

$$K_i = \tfrac{1}{2}I_i\omega^2 = \tfrac{1}{2}\left[\tfrac{1}{10}ML^2 + 2\left(\tfrac{1}{4}m\ell^2\right)\right]\omega^2 = \boxed{\tfrac{1}{20}\left(ML^2 + 5m\ell^2\right)\omega^2}$$

Express the final kinetic energy of the system and simplify to obtain:

$$K_f = \tfrac{1}{2} I_f \omega_f^2 = \tfrac{1}{2}\left[\tfrac{1}{10} ML^2 + 2\left(\tfrac{1}{4} mL^2\right)\right]\omega_f^2 = \tfrac{1}{20}\left(ML^2 + 5mL^2\right)\omega_f^2$$

$$= \tfrac{1}{20}\left(ML^2 + 5mL^2\right)\left(\frac{M + 5m\frac{\ell^2}{L^2}}{M + 5m}\omega\right)^2 = \tfrac{1}{20}\left[\frac{\left(ML + 5m\frac{\ell^2}{L}\right)^2}{M + 5m}\right]\omega^2$$

$$= \boxed{\tfrac{1}{20}\left[\frac{\left(ML^2 + 5m\ell^2\right)^2}{ML^2 + 5mL^2}\right]\omega^2}$$

85 ••

Determine the Concept Yes. The net external torque is zero and angular momentum is conserved as the system evolves from its initial to its final state. Because the disks come to the same final position, the initial and final configurations are the same as in Problem 84. Therefore, the answers are the same as for Problem 84.

86 ••

Picture the Problem Because the net torque acting on the system is zero; we can use conservation of angular momentum to relate the initial and final angular velocities of the system.

Using conservation of angular momentum, relate the initial and final angular velocities to the initial and final moments of inertia:

$$L_i = L_f$$

or

$$I_i\omega_i = I_f\omega_f$$

Solve for ω_f:

$$\omega_f = \frac{I_i}{I_f}\omega_i = \frac{I_i}{I_f}\omega \qquad (1)$$

Relate the tension in the string to the angular speed of the system and solve for and evaluate ω:

$$T = mr\omega^2 = m\frac{\ell}{2}\omega^2$$

and

$$\omega = \sqrt{\frac{2T}{m\ell}} = \sqrt{\frac{2(108\,\text{N})}{(0.4\,\text{kg})(0.6\,\text{m})}} = \boxed{30.0\,\text{rad/s}}$$

Express and evaluate I_i:

$$\begin{aligned} I_i &= \tfrac{1}{10}ML^2 + 2\left(\tfrac{1}{4}m\ell^2\right) \\ &= \tfrac{1}{10}(0.8\,\text{kg})(2\,\text{m})^2 + \tfrac{1}{2}(0.4\,\text{kg})(0.6\,\text{m})^2 \\ &= 0.392\,\text{kg}\cdot\text{m}^2 \end{aligned}$$

Express and evaluate I_f:

$$\begin{aligned} I_f &= \tfrac{1}{10}ML^2 + 2\left(\tfrac{1}{4}mL^2\right) \\ &= \tfrac{1}{10}(0.8\,\text{kg})(2\,\text{m})^2 + \tfrac{1}{2}(0.4\,\text{kg})(2\,\text{m})^2 \\ &= 1.12\,\text{kg}\cdot\text{m}^2 \end{aligned}$$

Substitute in equation (1) and solve for ω_f:

$$\begin{aligned} \omega_f &= \frac{I_i}{I_f}\omega = \frac{0.392\,\text{kg}\cdot\text{m}^2}{1.12\,\text{kg}\cdot\text{m}^2}(30.0\,\text{rad/s}) \\ &= \boxed{10.5\,\text{rad/s}} \end{aligned}$$

Express and evaluate the initial kinetic energy of the system:

$$\begin{aligned} K_i &= \tfrac{1}{2}I_i\omega^2 \\ &= \tfrac{1}{2}\left(0.392\,\text{kg}\cdot\text{m}^2\right)(30.0\,\text{rad/s})^2 \\ &= \boxed{176\,\text{J}} \end{aligned}$$

Express and evaluate the final kinetic energy of the system:

$$\begin{aligned} K_f &= \tfrac{1}{2}I_f\omega_f^2 \\ &= \tfrac{1}{2}\left(1.12\,\text{kg}\cdot\text{m}^2\right)(10.5\,\text{rad/s})^2 \\ &= \boxed{61.7\,\text{J}} \end{aligned}$$

87 ••

Picture the Problem Until the inelastic collision of the cylindrical objects at the ends of the cylinder, both angular momentum and energy are conserved. Let *K*' represent the kinetic energy of the system just before the disks reach the end of the cylinder and use conservation of energy to relate the initial and final kinetic energies to the final radial velocity.

Using conservation of mechanical energy, relate the initial and final kinetic energies of the disks:

$$K_i = K'$$

or

$$\tfrac{1}{2}I_i\omega^2 = \tfrac{1}{2}I_f\omega_f^2 + \tfrac{1}{2}\left(2mv_r^2\right)$$

Solve for v_r:

$$v_r = \sqrt{\frac{I_i\omega^2 - I_f\omega_f^2}{2m}} \qquad (1)$$

Using conservation of angular momentum, relate the initial and final angular velocities to the initial

$$L_i = L_f$$

or

and final moments of inertia:

$$I_i\omega_i = I_f\omega_f$$

Solve for ω_f:

$$\omega_f = \frac{I_i}{I_f}\omega = \frac{I_i}{I_f}\omega$$

Express I_i:

$$I_i = \tfrac{1}{10}ML^2 + 2\left(\tfrac{1}{4}m\ell^2\right)$$

Express I_f:

$$I_f = \tfrac{1}{10}ML^2 + 2\left(\tfrac{1}{4}mL^2\right)$$

Substitute to obtain ω_f in terms of ω:

$$\omega_f = \frac{\tfrac{1}{10}ML^2 + 2\left(\tfrac{1}{4}m\ell^2\right)}{\tfrac{1}{10}ML^2 + 2\left(\tfrac{1}{4}mL^2\right)}\omega = \frac{ML^2 + 5m\ell^2}{ML^2 + 5mL^2}\omega$$

Substitute in equation (1) and simplify to obtain:

$$v_r = \boxed{\frac{\ell\omega}{2L}\sqrt{\left(L^2 - \ell^2\right)}}$$

88 ••

Picture the Problem Because the net torque acting on the system is zero, we can use conservation of angular momentum to relate the initial and final angular velocities and the initial and final kinetic energy of the system.

Using conservation of angular momentum, relate the initial and final angular velocities to the initial and final moments of inertia:

$$L_i = L_f$$

or

$$I_i\omega_i = I_f\omega_f$$

Solve for ω_f:

$$\omega_f = \frac{I_i}{I_f}\omega_i = \frac{I_i}{I_f}\omega \qquad (1)$$

Relate the tension in the string to the angular speed of the system:

$$T = mr\omega^2 = m\frac{\ell}{2}\omega^2$$

Solve for ω:

$$\omega = \sqrt{\frac{2T}{m\ell}}$$

Substitute numerical values and evaluate ω:

$$\omega = \sqrt{\frac{2(108\,\text{N})}{(0.4\,\text{kg})(0.6\,\text{m})}} = \boxed{30.0\,\text{rad/s}}$$

Express and evaluate I_i:

$$I_i = \frac{1}{10}ML^2 + 2\left(\frac{1}{4}m\ell^2\right) = \frac{1}{10}(0.8\,\text{kg})(2\,\text{m})^2 + \frac{1}{2}(0.4\,\text{kg})(0.6\,\text{m})^2 = 0.392\,\text{kg}\cdot\text{m}^2$$

Letting L' represent the final separation of the disks, express and evaluate I_f:

$$I_f = \frac{1}{10}ML^2 + 2\left(\frac{1}{4}mL'^2\right) = \frac{1}{10}(0.8\,\text{kg})(2\,\text{m})^2 + \frac{1}{2}(0.4\,\text{kg})(1.6\,\text{m})^2 = 0.832\,\text{kg}\cdot\text{m}^2$$

Substitute in equation (1) and solve for ω_f:

$$\omega_f = \frac{I_i}{I_f}\omega = \frac{0.392\,\text{kg}\cdot\text{m}^2}{0.832\,\text{kg}\cdot\text{m}^2}(30.0\,\text{rad/s}) = 14.1\,\text{rad/s}$$

Express and evaluate the initial kinetic energy of the system:

$$K_i = \frac{1}{2}I_i\omega^2 = \frac{1}{2}(0.392\,\text{kg}\cdot\text{m}^2)(30.0\,\text{rad/s})^2 = \boxed{176\,\text{J}}$$

Express and evaluate the final kinetic energy of the system:

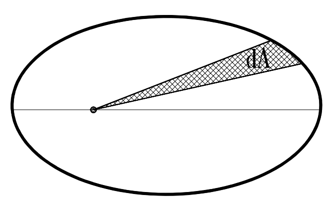
$$K_f = \frac{1}{2}I_f\omega_f^2 = \frac{1}{2}(0.832\,\text{kg}\cdot\text{m}^2)(14.1\,\text{rad/s})^2 = \boxed{82.7\,\text{J}}$$

The energy dissipated in friction is:

$$\Delta E = K_i - K_f = 176\,\text{J} - 82.7\,\text{J} = \boxed{93.3\,\text{J}}$$

***89 ••**

Picture the Problem The drawing shows an elliptical orbit. The triangular element of the area is $dA = \frac{1}{2}r(rd\theta) = \frac{1}{2}r^2 d\theta$.



Differentiate dA with respect to t to obtain:

$$\frac{dA}{dt} = \frac{1}{2}r^2\frac{d\theta}{dt} = \frac{1}{2}r^2\omega$$

Because the gravitational force acts along the line joining the two objects, $\tau = 0$ and:

$$L = mr^2\omega = \text{constant}$$

Eliminate $r^2\omega$ between the two equations to obtain:

$$\frac{dA}{dt}=\boxed{\frac{L}{2m}=\text{constant}}$$

90 ••

Picture the Problem Let x be the radial distance each disk moves outward. Because the net torque acting on the system is zero, we can use conservation of angular momentum to relate the initial and final angular velocities to the initial and final moments of inertia. We'll assume that the disks are thin enough so that we can ignore their lengths in expressing their moments of inertia.

Use conservation of angular momentum to relate the initial and final angular velocities of the disks:

$$L_\text{i}=L_\text{f}$$

or

$$I_\text{i}\omega_\text{i}=I_\text{f}\omega_\text{f}$$

Solve for ω_f:

$$\omega_\text{f}=\frac{I_\text{i}}{I_\text{f}}\omega_\text{i} \qquad (1)$$

Express the initial moment of inertia of the system:

$$I_\text{i}=I_\text{cyl}+2I_\text{disk}$$

Express the moment of inertia of the cylinder:

$$\begin{aligned}I_\text{cyl}&=\tfrac{1}{12}ML^2+\tfrac{1}{2}MR^2\\&=\tfrac{1}{12}M\left(L^2+6R^2\right)\\&=\tfrac{1}{12}(0.8\,\text{kg})\left[(1.8\,\text{m})^2+6(0.2\,\text{m})^2\right]\\&=0.232\,\text{kg}\cdot\text{m}^2\end{aligned}$$

Letting ℓ represent the distance of the clamped disks from the center of rotation and ignoring the thickness of each disk (we're told they are thin), use the parallel-axis theorem to express the moment of inertia of each disk:

$$\begin{aligned}I_\text{disk}&=\tfrac{1}{4}mr^2+m\ell^2\\&=\tfrac{1}{4}m\left(r^2+4\ell^2\right)\\&=\tfrac{1}{4}(0.2\,\text{kg})\left[(0.2\,\text{m})^2+4(0.4\,\text{m})^2\right]\\&=0.0340\,\text{kg}\cdot\text{m}^2\end{aligned}$$

With the disks clamped:

$$\begin{aligned}I_\text{i}&=I_\text{cyl}+2I_\text{disk}\\&=0.232\,\text{kg}\cdot\text{m}^2+2\left(0.0340\,\text{kg}\cdot\text{m}^2\right)\\&=0.300\,\text{kg}\cdot\text{m}^2\end{aligned}$$

With the disks unclamped, $\ell = 0.6$ m and:

$$I_{\text{disk}} = \tfrac{1}{4}m\left(r^2 + 4\ell^2\right) = \tfrac{1}{4}(0.2\,\text{kg})\left[(0.2\,\text{m})^2 + 4(0.6\,\text{m})^2\right] = 0.0740\,\text{kg}\cdot\text{m}^2$$

Express and evaluate the final moment of inertia of the system:

$$I_{\text{f}} = I_{\text{cyl}} + 2I_{\text{disk}} = 0.232\,\text{kg}\cdot\text{m}^2 + 2\left(0.0740\,\text{kg}\cdot\text{m}^2\right) = 0.380\,\text{kg}\cdot\text{m}^2$$

Substitute in equation (1) to determine ω_{f}:

$$\omega_{\text{f}} = \frac{0.300\,\text{kg}\cdot\text{m}^2}{0.380\,\text{kg}\cdot\text{m}^2}(8\,\text{rad/s}) = \boxed{6.32\,\text{rad/s}}$$

Express the energy dissipated in friction:

$$\Delta E = E_{\text{i}} - E_{\text{f}} = \tfrac{1}{2}I_{\text{i}}\omega_{\text{i}}^2 - \left(\tfrac{1}{2}I_{\text{f}}\omega_{\text{f}}^2 + \tfrac{1}{2}kx^2\right)$$

Apply Newton's 2nd law to each disk when they are in their final positions:

$$\sum F_{\text{radial}} = kx = mr\omega^2$$

Solve for k:

$$k = \frac{mr\omega^2}{x}$$

Substitute numerical values and evaluate k:

$$k = \frac{(0.2\,\text{kg})(0.6\,\text{m})(6.32\,\text{rad/s})^2}{0.2\,\text{m}} = 24.0\,\text{N/m}$$

Express the energy dissipated in friction:

$$W_{\text{fr}} = E_{\text{i}} - E_{\text{f}} = \tfrac{1}{2}I_{\text{i}}\omega_{\text{i}}^2 - \left(\tfrac{1}{2}I_{\text{f}}\omega_{\text{f}}^2 + \tfrac{1}{2}kx^2\right)$$

Substitute numerical values and evaluate W_{fr}:

$$W_{\text{fr}} = \tfrac{1}{2}\left(0.300\,\text{kg}\cdot\text{m}^2\right)(8\,\text{rad/s})^2 - \tfrac{1}{2}\left(0.380\,\text{kg}\cdot\text{m}^2\right)(6.32\,\text{rad/s})^2 - \tfrac{1}{2}(24\,\text{N/m})(0.2\,\text{m})^2 = \boxed{1.53\,\text{J}}$$

91 ••

Picture the Problem Let the letters *d*, *m*, and *r* denote the disk and the letters *t*, *M*, and *R* the turntable. We can use conservation of angular momentum to relate the final angular speed of the turntable to the initial angular speed of the Euler disk and the moments of inertia of the turntable and the disk. In part (*b*) we'll need to use the parallel-axis theorem to express the moment of inertia of the disk with respect to the rotational axis of the turntable. You can find the moments of inertia of the disk in its two orientations and that of the turntable in Table 9-1.

(*a*) Use conservation of angular momentum to relate the initial and final angular momenta of the system:

$$I_{\rm di}\omega_{\rm di} = I_{\rm df}\omega_{\rm df} + I_{\rm tf}\omega_{\rm tf}$$

Because $\omega_{\rm tf} = \omega_{\rm df}$:

$$I_{\rm di}\omega_{\rm di} = I_{\rm df}\omega_{\rm tf} + I_{\rm tf}\omega_{\rm tf}$$

Solve for $\omega_{\rm tf}$:

$$\omega_{\rm tf} = \frac{I_{\rm di}}{I_{\rm df} + I_{\rm tf}}\omega_{\rm di} \qquad (1)$$

Ignoring the negligible thickness of the disk, express its initial moment of inertia:

$$I_{\rm di} = \tfrac{1}{4}mr^2$$

Express the final moment of inertia of the disk:

$$I_{\rm df} = \tfrac{1}{2}mr^2$$

Express the final moment of inertia of the turntable:

$$I_{\rm tf} = \tfrac{1}{2}MR^2$$

Substitute in equation (1) to obtain:

$$\omega_{\rm tf} = \frac{\tfrac{1}{4}mr^2}{\tfrac{1}{2}mr^2 + \tfrac{1}{2}MR^2}\omega_{\rm di} = \frac{1}{2 + 2\dfrac{MR^2}{mr^2}}\omega_{\rm di} \qquad (2)$$

Express $\omega_{\rm di}$ in rad/s:

$$\omega_{\rm di} = 30\,\frac{\rm rev}{\rm min}\times\frac{2\pi\,\rm rad}{\rm rev}\times\frac{1\,\rm min}{60\,\rm s} = \pi\,\rm rad/s$$

Substitute numerical values in equation (2) and evaluate $\omega_{\rm tf}$:

$$\omega_{\rm tf} = \frac{\pi\,\rm rad/s}{2 + 2\dfrac{(0.735\,\rm kg)(0.25\,\rm m)^2}{(0.5\,\rm kg)(0.125\,\rm m)^2}} = \boxed{0.228\,\rm rad/s}$$

(*b*) Use the parallel-axis theorem to express the final moment of inertia of the disk when it is a distance L from the center of the turntable:

$$I_{\rm df} = \tfrac{1}{2}mr^2 + mL^2 = m\left(\tfrac{1}{2}r^2 + L^2\right)$$

Substitute in equation (1) to obtain:

$$\omega_{\text{tf}} = \frac{\frac{1}{4}mr^2}{m\left(\frac{1}{2}r^2 + L^2\right) + \frac{1}{2}MR^2}\omega_{\text{di}} = \frac{1}{2 + 4\dfrac{L^2}{r^2} + 2\dfrac{MR^2}{mr^2}}\omega_{\text{di}}$$

Substitute numerical values and evaluate ω_{tf}:

$$\omega_{\text{tf}} = \frac{\pi\ \text{rad/s}}{2 + 4\dfrac{(0.1\,\text{m})^2}{(0.125\,\text{m})^2} + 2\dfrac{(0.735\,\text{kg})(0.25\,\text{m})^2}{(0.5\,\text{kg})(0.125\,\text{m})^2}} = \boxed{0.192\,\text{rad/s}}$$

92 ••

Picture the Problem We can express the period of the earth's rotation in terms of its angular velocity of rotation and relate its angular velocity to its angular momentum and moment of inertia with respect to an axis through its center. We can differentiate this expression with respect to *T* and then use differentials to approximate the changes in *r* and *T*.

(*a*) Express the period of the earth's rotation in terms of its angular velocity of rotation:

$$T = \frac{2\pi}{\omega}$$

Relate the earth's angular velocity of rotation to its angular momentum and moment of inertia:

$$\omega = \frac{L}{I} = \frac{L}{\frac{2}{5}mr^2}$$

Substitute and simplify to obtain:

$$T = \frac{2\pi\left(\frac{2}{5}mr^2\right)}{L} = \boxed{\frac{4\pi m}{5L}r^2}$$

(*b*) Find dT/dr:

$$\frac{dT}{dr} = 2\left(\frac{4\pi m}{5L}\right)r = 2\left(\frac{T}{r^2}\right)r = \frac{2T}{r}$$

Solve for dT/T:

$$\frac{dT}{T} = 2\frac{dr}{r} \text{ or } \boxed{\frac{\Delta T}{T} \approx 2\frac{\Delta r}{r}}$$

(*c*) Using the equation we just derived, substitute for the change in the period of the earth:

$$\frac{\Delta T}{T} = \frac{\frac{1}{4}\text{d}}{\text{y}} \times \frac{1\,\text{y}}{365.24\,\text{d}} = \frac{1}{1460} = 2\frac{\Delta r}{r}$$

Solve for and evaluate Δr:

$$\Delta r = \frac{r}{2(1460)} = \frac{6.37\times10^{3}\text{ km}}{2(1460)} = \boxed{2.18\,\text{km}}$$

***93** ••

Picture the Problem Let ω_P be the angular velocity of precession of the earth-as-gyroscope, ω_s its angular velocity about its spin axis, and I its moment of inertia with respect to an axis through its poles, and relate ω_P to ω_s and I using its definition.

Use its definition to express the precession rate of the earth as a giant gyroscope:

$$\omega_P = \frac{\tau}{L}$$

Substitute for I and solve for τ:

$$\tau = L\omega_P = I\omega\omega_P$$

Express the angular velocity ω_s of the earth about its spin axis:

$\omega = \frac{2\pi}{T}$ where T is the period of rotation of the earth.

Substitute to obtain:

$$\tau = \frac{2\pi I\omega_P}{T}$$

Substitute numerical values and evaluate τ:

$$\tau = \frac{2\pi\left(8.03\times10^{37}\text{ kg}\cdot\text{m}^2\right)\left(7.66\times10^{-12}\text{ s}^{-1}\right)}{1\,\text{d}\times\frac{24\,\text{h}}{\text{d}}\times\frac{3600\,\text{s}}{\text{h}}} = \boxed{4.47\times10^{22}\text{ N}\cdot\text{m}}$$

94 •••

Picture the Problem The applied torque accelerates the system and increases the tension in the string until it breaks. The work done before the string breaks is the change in the kinetic energy of the system. We can use Newton's 2nd law to relate the breaking tension to the angular velocity of the system at the instant the string breaks. Once the applied torque is removed, angular momentum is conserved.

Express the work done before the string breaks:

$$W = \Delta K = K_f = \tfrac{1}{2}I_f\omega_f^2 \qquad (1)$$

Express the moment of inertia of the system (see Table 9-1):

$$\begin{aligned} I &= I_{cyl} + 2I_m = I(x) = \tfrac{1}{12}M_{cyl}L_{cyl}^2 + 2mx^2 \\ &= \tfrac{1}{12}(1.2\,\text{kg})(1.6\,\text{m})^2 + 2(0.4\,\text{kg})x^2 \\ &= 0.256\,\text{kg}\cdot\text{m}^2 + (0.8\,\text{kg})x^2 \end{aligned}$$

Evaluate $I_f = I(0.4\text{ m})$:

$$I_f = I(0.4\,\text{m}) = 0.256\,\text{kg}\cdot\text{m}^2 + (0.8\,\text{kg})(0.4\,\text{m})^2 = 0.384\,\text{kg}\cdot\text{m}^2$$

Using Newton's 2nd law, relate the forces acting on a disk to its angular velocity:

$$\sum F_{\text{radial}} = T = mr\omega_f^2$$

where T is the tension in the string at which it breaks.

Solve for ω_f:

$$\omega_f = \sqrt{\frac{T}{mr}}$$

Substitute numerical values and evaluate ω_f:

$$\omega_f = \sqrt{\frac{100\,\text{N}}{(0.4\,\text{kg})(0.4\,\text{m})}} = 25.0\,\text{rad/s}$$

Substitute in equation (1) to express the work done before the string breaks:

$$W = \tfrac{1}{2}I_f\omega_f^2$$

Substitute numerical values and evaluate W:

$$W = \tfrac{1}{2}(0.384\,\text{kg}\cdot\text{m}^2)(25\,\text{rad/s})^2 = \boxed{120\,\text{J}}$$

With the applied torque removed, angular momentum is conserved and we can express the angular momentum as a function of x:

$$L = I_f\omega_f = I(x)\omega(x)$$

Solve for $\omega(x)$:

$$\omega(x) = \frac{I_f\omega_f}{I(x)}$$

Substitute numerical values to obtain:

$$\omega(x) = \frac{(0.384\,\text{kg}\cdot\text{m}^2)(25\,\text{rad/s})}{0.256\,\text{kg}\cdot\text{m}^2 + (0.8\,\text{kg})x^2} = \boxed{\frac{9.60\,\text{J}\cdot\text{s}}{0.256\,\text{kg}\cdot\text{m}^2 + (0.8\,\text{kg})x^2}}$$

95 •••

Picture the Problem The applied torque accelerates the system and increases the tension in the string until it breaks. The work done before the string breaks is the change in the kinetic energy of the system. We can use Newton's 2nd law to relate the breaking tension to the angular velocity of the system at the instant the string breaks. Once the applied torque is removed, angular momentum is conserved.

Express the work done before the string breaks:

$$W = \Delta K = K_f = \tfrac{1}{2} I_f \omega_f^2 \qquad (1)$$

Express the moment of inertia of the system (see Table 9-1):

$$I = I_{cyl} + 2I_m = I(x) = \tfrac{1}{12} M_{cyl} L_{cyl}^2 + 2mx^2$$

Substitute numerical values to obtain:

$$I = \tfrac{1}{12}(1.2\,\text{kg})(1.6\,\text{m})^2 + 2(0.4\,\text{kg})x^2$$
$$= 0.256\,\text{kg}\cdot\text{m}^2 + (0.8\,\text{kg})x^2$$

Evaluate $I_f = I(0.4\text{ m})$:

$$I_f = I(0.4\,\text{m})$$
$$= 0.256\,\text{kg}\cdot\text{m}^2 + (0.8\,\text{kg})(0.4\,\text{m})^2$$
$$= 0.384\,\text{kg}\cdot\text{m}^2$$

Using Newton's 2nd law, relate the forces acting on a disk to its angular velocity:

$$\sum F_{rad} = T = mr\omega_f^2$$

where T is the tension in the string at which it breaks.

Solve for ω_f:

$$\omega_f = \sqrt{\frac{T}{mr}}$$

Substitute numerical values and evaluate ω_f:

$$\omega_f = \sqrt{\frac{100\,\text{N}}{(0.4\,\text{kg})(0.4\,\text{m})}} = 25.0\,\text{rad/s}$$

With the applied torque removed, angular momentum is conserved and we can express the angular momentum as a function of x:

$$L = I_f \omega_f$$
$$= I(x)\omega(x)$$

Solve for $\omega(x)$:

$$\omega(x) = \frac{I_f \omega_f}{I(x)}$$

Substitute numerical values and simplify to obtain:

$$\omega(x) = \frac{(0.384\,\text{kg}\cdot\text{m}^2)(25\,\text{rad/s})}{0.256\,\text{kg}\cdot\text{m}^2 + (0.8\,\text{kg})x^2} = \frac{9.60\,\text{J}\cdot\text{s}}{0.256\,\text{kg}\cdot\text{m}^2 + (0.8\,\text{kg})x^2}$$

Evaluate $\omega(0.8\,\text{m})$:

$$\omega(0.8\,\text{m}) = \frac{9.60\,\text{J}\cdot\text{s}}{0.256\,\text{kg}\cdot\text{m}^2 + (0.8\,\text{kg})(0.8\,\text{m})^2} = \boxed{12.5\,\text{rad/s}}$$

Remarks: Note that this is the angular velocity in both instances. Because the disks leave the cylinder with a tangential velocity of $\frac{1}{2}L\omega$, the angular momentum of the system remains constant.

96 •••

Picture the Problem The applied torque accelerates the system and increases the tension in the string until it breaks. The work done before the string breaks is the change in the kinetic energy of the system. We can use Newton's 2nd law to relate the breaking tension to the angular velocity of the system at the instant the string breaks. Once the applied torque is removed, angular momentum is conserved.

Express the work done before the string breaks:

$$W = \Delta K = K_\text{f} = \tfrac{1}{2}I_\text{f}\omega_\text{f}^2 \qquad (1)$$

Using the parallel axis theorem and treating the disks as thin disks, express the moment of inertia of the system (see Table 9-1):

$$\begin{aligned} I(x) &= I_\text{cyl} + 2I_\text{m} \\ &= \tfrac{1}{12}ML^2 + \tfrac{1}{2}MR^2 + 2\left(\tfrac{1}{4}mR^2 + mx^2\right) \\ &= \tfrac{1}{12}M\left(L^2 + 6R^2\right) + 2m\left(\tfrac{1}{4}R^2 + x^2\right) \end{aligned}$$

Substitute numerical values to obtain:

$$\begin{aligned} I(x) &= \tfrac{1}{12}(1.2\,\text{kg})\left[(1.6\,\text{m})^2 + 6(0.4\,\text{m})^2\right] \\ &\quad + 2(0.4\,\text{kg})\left[\tfrac{1}{4}(0.4\,\text{m})^2 + x^2\right] \\ &= 0.384\,\text{kg}\cdot\text{m}^2 + (0.8\,\text{kg})x^2 \end{aligned}$$

Evaluate $I_\text{f} = I(0.4\text{ m})$:

$$\begin{aligned} I_\text{f} &= I(0.4\,\text{m}) \\ &= 0.384\,\text{kg}\cdot\text{m}^2 + (0.8\,\text{kg})(0.4\,\text{m})^2 \\ &= 0.512\,\text{kg}\cdot\text{m}^2 \end{aligned}$$

Using Newton's 2nd law, relate the forces acting on a disk to its angular velocity:

$$\sum F_\text{rad} = T = mr\omega_\text{f}^2$$

where T is the tension in the string at which it breaks.

Solve for ω_f:

$$\omega_\text{f} = \sqrt{\frac{T}{mr}}$$

Substitute numerical values and evaluate ω_f:

$$\omega_\text{f} = \sqrt{\frac{100\,\text{N}}{(0.4\,\text{kg})(0.4\,\text{m})}} = 25.0\,\text{rad/s}$$

Substitute in equation (1) to express the work done before the string breaks:

$$W = \tfrac{1}{2} I_f \omega_f^2$$

Substitute numerical values and evaluate W:

$$W = \tfrac{1}{2}\left(0.512\,\text{kg}\cdot\text{m}^2\right)\left(25\,\text{rad/s}\right)^2 = \boxed{160\,\text{J}}$$

With the applied torque removed, angular momentum is conserved and we can express the angular momentum as a function of x:

$$L = I_f \omega_f = I(x)\omega(x)$$

Solve for $\omega(x)$:

$$\omega(x) = \frac{I_f \omega_f}{I(x)}$$

Substitute numerical values to obtain:

$$\omega(x) = \frac{\left(0.512\,\text{kg}\cdot\text{m}^2\right)\left(25\,\text{rad/s}\right)}{0.384\,\text{kg}\cdot\text{m}^2 + (0.8\,\text{kg})x^2} = \boxed{\frac{12.8\,\text{J}\cdot\text{s}}{0.384\,\text{kg}\cdot\text{m}^2 + (0.8\,\text{kg})x^2}}$$

***97 •••**

Picture the Problem Let the origin of the coordinate system be at the center of the pulley with the upward direction positive. Let λ be the linear density (mass per unit length) of the rope and L_1 and L_2 the lengths of the hanging parts of the rope. We can use conservation of mechanical energy to find the angular velocity of the pulley when the difference in height between the two ends of the rope is 7.2 m.

(*a*) Apply conservation of energy to relate the final kinetic energy of the system to the change in potential energy:

$$\Delta K + \Delta U = 0$$

or, because $K_i = 0$,

$$K + \Delta U = 0 \qquad (1)$$

Express the change in potential energy of the system:

$$\begin{aligned}\Delta U &= U_f - U_i \\ &= -\tfrac{1}{2}L_{1f}(L_{1f}\lambda)g - \tfrac{1}{2}L_{2f}(L_{2f}\lambda)g \\ &\quad -\left[-\tfrac{1}{2}L_{1i}(L_{1i}\lambda)g - \tfrac{1}{2}L_{2i}(L_{2i}\lambda)g\right] \\ &= -\tfrac{1}{2}\left(L_{1f}^2 + L_{2f}^2\right)\lambda g + \tfrac{1}{2}\left(L_{1i}^2 + L_{2i}^2\right)\lambda g \\ &= -\tfrac{1}{2}\lambda g\left[\left(L_{1f}^2 + L_{2f}^2\right) - \left(L_{1i}^2 + L_{2i}^2\right)\right]\end{aligned}$$

Because $L_1 + L_2 = 7.4$ m, $L_{2i} - L_{1i} = 0.6$ m, and $L_{2f} - L_{1f} = 7.2$ m, we obtain:

$L_{1i} = 3.4$ m, $L_{2i} = 4.0$ m, $L_{1f} = 0.1$ m, and $L_{2f} = 7.3$ m.

Substitute numerical values and evaluate ΔU:

$$\begin{aligned}\Delta U &= -\tfrac{1}{2}(0.6\,\text{kg/m})(9.81\,\text{m/s}^2)\\ &\quad\times\left[(0.1\,\text{m})^2 + (7.3\,\text{m})^2 - (3.4\,\text{m})^2 - (4\,\text{m})^2\right]\\ &= -75.75\,\text{J}\end{aligned}$$

Express the kinetic energy of the system when the difference in height between the two ends of the rope is 7.2 m:

$$\begin{aligned}K &= \tfrac{1}{2}I_\text{p}\omega^2 + \tfrac{1}{2}Mv^2\\ &= \tfrac{1}{2}\left(\tfrac{1}{2}M_\text{p}R^2\right)\omega^2 + \tfrac{1}{2}MR^2\omega^2\\ &= \tfrac{1}{2}\left(\tfrac{1}{2}M_\text{p} + M\right)R^2\omega^2\end{aligned}$$

Substitute numerical values and simplify:

$$\begin{aligned}K &= \tfrac{1}{2}\left[\tfrac{1}{2}(2.2\,\text{kg}) + 4.8\,\text{kg}\right]\left(\frac{1.2\,\text{m}}{2\pi}\right)^2\omega^2\\ &= \left(0.1076\,\text{kg}\cdot\text{m}^2\right)\omega^2\end{aligned}$$

Substitute in equation (1) and solve for ω:

$$\left(0.1076\,\text{kg}\cdot\text{m}^2\right)\omega^2 - 75.75\,\text{J} = 0$$

and

$$\omega = \sqrt{\frac{75.75\,\text{J}}{0.1076\,\text{kg}\cdot\text{m}^2}} = \boxed{26.5\,\text{rad/s}}$$

(*b*) Noting that the moment arm of each portion of the rope is the same, express the total angular momentum of the system:

$$\begin{aligned}L &= L_\text{p} + L_\text{r} = I_\text{p}\omega + M_\text{r}R^2\omega\\ &= \left(\tfrac{1}{2}M_\text{p}R^2 + M_\text{r}R^2\right)\omega \qquad (2)\\ &= \left(\tfrac{1}{2}M_\text{p} + M_\text{r}\right)R^2\omega\end{aligned}$$

Letting θ be the angle through which the pulley has turned, express $U(\theta)$:

$$U(\theta) = -\tfrac{1}{2}\left[(L_{1i} - R\theta)^2 + (L_{2i} + R\theta)^2\right]\lambda g$$

Express ΔU and simplify to obtain:

$$\begin{aligned}\Delta U &= U_\text{f} - U_\text{i} = U(\theta) - U(0)\\ &= -\tfrac{1}{2}\left[(L_{1i} - R\theta)^2 + (L_{2i} + R\theta)^2\right]\lambda g\\ &\quad + \tfrac{1}{2}\left(L_{1i}^2 + L_{2i}^2\right)\lambda g\\ &= -R^2\theta^2\lambda g + (L_{1i} - L_{2i})R\theta\lambda g\end{aligned}$$

Assuming that, at $t = 0$, $L_{1i} \approx L_{2i}$:

$$\Delta U \approx -R^2\theta^2\lambda g$$

Substitute for K and ΔU in equation (1) to obtain:

$$\left(0.1076\,\text{kg}\cdot\text{m}^2\right)\omega^2 - R^2\theta^2\lambda g = 0$$

Solve for ω:

$$\omega = \sqrt{\frac{R^2\theta^2\lambda g}{0.1076\,\text{kg}\cdot\text{m}^2}}$$

Substitute numerical values to obtain:

$$\omega = \sqrt{\frac{\left(\frac{1.2\,\text{m}}{2\pi}\right)^2\left(0.6\,\text{kg/m}\right)\left(9.81\,\text{m/s}^2\right)}{0.1076\,\text{kg}\cdot\text{m}^2}}\,\theta = \left(1.41\,\text{s}^{-1}\right)\theta$$

Express ω as the rate of change of θ:

$$\frac{d\theta}{dt} = \left(1.41\,\text{s}^{-1}\right)\theta \Rightarrow \frac{d\theta}{\theta} = \left(1.41\,\text{s}^{-1}\right)dt$$

Integrate θ from 0 to θ to obtain:

$$\ln\theta = \left(1.41\,\text{s}^{-1}\right)t$$

Transform from logarithmic to exponential form to obtain:

$$\theta(t) = e^{\left(1.41\,\text{s}^{-1}\right)t}$$

Differentiate to express ω as a function of time:

$$\omega(t) = \frac{d\theta}{dt} = \left(1.41\,\text{s}^{-1}\right)e^{\left(1.41\,\text{s}^{-1}\right)t}$$

Substitute for ω in equation (2) to obtain:

$$L = \left(\tfrac{1}{2}M_\text{p} + M_\text{r}\right)R^2\left(1.41\,\text{s}^{-1}\right)e^{\left(1.41\,\text{s}^{-1}\right)t}$$

Substitute numerical values and evaluate L:

$$L = \left[\tfrac{1}{2}\left(2.2\,\text{kg}\right) + \left(4.8\,\text{kg}\right)\right]\left(\frac{1.2\,\text{m}}{2\pi}\right)^2\left[\left(1.41\,\text{s}^{-1}\right)e^{\left(1.41\,\text{s}^{-1}\right)t}\right] = \boxed{\left(0.303\,\text{kg}\cdot\text{m}^2/\text{s}\right)e^{\left(1.41\,\text{s}^{-1}\right)t}}$$

Chapter 11
Gravity

Conceptual Problems

***1** •

(a) False. Kepler's law of equal areas is a consequence of the fact that the gravitational force acts along the line joining two bodies but is independent of the manner in which the force varies with distance.

(b) True. The periods of the planets vary with the three-halves power of their distances from the sun. So the shorter the distance from the sun, the shorter the period of the planet's motion.

2 •

Determine the Concept We can apply Newton's 2nd law and the law of gravity to the satellite to obtain an expression for its speed as a function of the radius of its orbit.

Apply Newton's 2nd law to the satellite to obtain:

$$\sum F_{\text{radial}} = \frac{GMm}{r^2} = m\frac{v^2}{r}$$

where M is the mass of the object the satellite is orbiting and m is the mass of the satellite.

Solve for v to obtain:

$$v = \sqrt{\frac{GM}{r}}$$

Thus the speed of the satellite is independent of its mass and:

$$\boxed{(c)\text{ is correct.}}$$

3 ••

Picture the Problem The acceleration due to gravity varies inversely with the square of the distance from the center of the moon.

Express the dependence of the acceleration due to the gravity of the moon on the distance from its center:

$$a' \propto \frac{1}{r^2}$$

Express the dependence of the acceleration due to the gravity of the moon at its surface on its radius:

$$a \propto \frac{1}{R_{\text{M}}^2}$$

Divide the first of these expressions by the second to obtain:

$$\frac{a'}{a}=\frac{R_M^2}{r^2}$$

Solve for a':

$$a'=\frac{R_M^2}{r^2}a=\frac{R_M^2}{(4R_M)^2}a=\tfrac{1}{16}a$$

and $\boxed{(d)\text{ is correct.}}$

4 •

Determine the Concept Measurement of G is difficult because masses accessible in the laboratory are very small compared to the mass of the earth.

5 •

Determine the Concept The escape speed for a planet is given by $v_e=\sqrt{2Gm/R}$.

Between v_e depends on the square root of M, doubling M increases the escape speed by a factor of $\sqrt{2}$ and $\boxed{(a)\text{ is correct.}}$

6 ••

Determine the Concept We can take careful measurements of its position in order to determine whether its trajectory is an ellipse, a hyperbola, or a parabola. If the path is an ellipse, it will return; if its path is hyperbolic or parabolic, it will not return.

7 ••

Determine the Concept The gravitational field is proportional to the mass within the sphere of radius r *and* inversely proportional to the square of r, i.e., proportional to $r^3/r^2=r$.

***8 •**

Determine the Concept Let m represent the mass of Mercury, M_S the mass of the sun, v the orbital speed of Mercury, and R the mean orbital radius of Mercury. We can use Newton's 2nd law of motion to relate the gravitational force acting on the Mercury to its orbital speed.

Use Newton's 2nd law to relate the gravitational force acting on Mercury to its orbital speed:

$$F_{net}=\frac{GM_Sm}{R^2}=m\frac{v^2}{R}$$

Simplify to obtain:

$$\tfrac{1}{2}mv^2=\tfrac{1}{2}\frac{GM_Sm}{R}=-\tfrac{1}{2}\left(-\frac{GM_Sm}{R}\right)$$
$$=-\tfrac{1}{2}U$$

or $\boxed{K = -\frac{1}{2}U}$

9 ••

Picture the Problem We can use the definition of the gravitational field to express the ratio of the student's weight at an elevation of two earth radii to her weight at the surface of the earth.

Express the weight of the student at the surface of the earth:

$$w = mg = \frac{GM_E m}{R_E^2}$$

Express the weight of the student at an elevation of two earth radii:

$$w' = mg' = \frac{GM_E m}{(3R_E)^2}$$

Express the ratio of w' to w:

$$\frac{w'}{w} = \frac{\frac{GM_E m}{(3R_E)^2}}{\frac{GM_E m}{R_E^2}} = \frac{1}{9} \text{ and } \boxed{(d) \text{ is correct.}}$$

10 ••

Determine the Concept One such machine would be a balance wheel with weights attached to the rim with half of them shielded using Cavourite. The weights on one side would be pulled down by the force of gravity, while the other side would not, leading to rotation, which can be converted into useful work, in violation of the law of the conservation of energy.

Estimation and Approximation

11 •

Picture the Problem To approximate the mass of the galaxy we'll assume the galactic center to be a point mass with the sun in orbit about it and apply Kepler's 3rd law.

Using Kepler's 3rd law, relate the period of the sun T to its mean distance r from the center of the galaxy:

$$T^2 = \frac{4\pi^2}{GM_{galaxy}}r^3 = \frac{\frac{4\pi^2}{M_s}}{G\frac{M_{galaxy}}{M_s}}r^3$$

Solve for $\frac{r^3}{T^2}$ to obtain:

$$\frac{r^3}{T^2} = \frac{G\frac{M_{galaxy}}{M_s}}{\frac{4\pi^2}{M_s}} = \frac{\frac{M_{galaxy}}{M_s}}{\frac{4\pi^2}{GM_s}}$$

If we measure distances in AU and times in years:

$$\frac{4\pi^2}{GM_s}=1 \text{ and } \frac{r^3}{T^2}=\frac{M_{galaxy}}{M_s}$$

Substitute numerical values and evaluate M_{galaxy}/M_s:

$$\frac{M_{galaxy}}{M_s}=\frac{\left(3\times10^4\,\text{LY}\times\frac{6.3\times10^4\,\text{AU}}{\text{LY}}\right)^3}{\left(250\times10^6\,\text{y}\right)^2}$$
$$=1.08\times10^{11}$$

or

$$M_{galaxy}=\boxed{1.08\times10^{11}M_s}$$

***12 •••**

Picture the Problem We can use Kepler's 3rd law to find the size of the semi-major axis of the planet's orbit and the conservation of momentum to find its mass.

(*a*) Using Kepler's 3rd law, relate the period of this planet T to the length r of its semi-major axis:

$$T^2=\frac{4\pi^2}{GM_{\text{Iota Draconis}}}r^3$$
$$=\frac{\frac{4\pi^2}{M_s}}{G\frac{M_{\text{Iota Draconis}}}{M_s}}r^3$$
$$=\frac{\frac{4\pi^2}{GM_s}}{\frac{M_{\text{Iota Draconis}}}{M_s}}r^3$$

If we measure time in years, distances in AU, and masses in terms of the mass of the sun:

$$\frac{4\pi^2}{MG_s}=1 \text{ and } T^2=\frac{1}{\frac{M_{\text{Iota Draconis}}}{M_s}}r^3$$

Solve for r to obtain:

$$r=\sqrt[3]{\frac{M_{\text{Iota Draconis}}}{M_s}T^2}$$

Substitute numerical values and evaluate r:

$$r=\sqrt[3]{\left(\frac{1.05M_s}{M_s}\right)(1.5\,\text{y})^2}=\boxed{1.33\,\text{AU}}$$

(*b*) Apply conservation of momentum to the planet (mass m and speed v) and the star (mass $M_{\text{Iota Draconis}}$ and speed V) to obtain:

$$mv=M_{\text{Iota Draconis}}V$$

Solve for m to obtain:

$$m = M_{\text{Iota Draconis}} \frac{V}{v}$$

Use its definition to find the speed of the orbiting planet:

$$v = \frac{\Delta d}{\Delta t} = \frac{2\pi r}{T}$$

$$= \frac{2\pi\left(1.33\,\text{AU} \times \frac{1.5\times10^{11}\,\text{m}}{\text{AU}}\right)}{1.50\,\text{y} \times \frac{365.25\,\text{d}}{\text{y}} \times \frac{24\,\text{h}}{\text{d}} \times \frac{3600\,\text{s}}{\text{h}}}$$

$$= 2.65\times10^{4}\ \text{m/s}$$

Substitute numerical values and evaluate v:

$$m = M_{\text{Iota Draconis}}\left(\frac{296\,\text{m/s}}{2.65\times10^{4}\,\text{m/s}}\right)$$

$$= 0.0112 M_{\text{Iota Draconis}}$$

$$= 0.0112(1.05 M_{\text{sun}})$$

$$= 0.0112(1.05)(1.99\times10^{30}\,\text{kg})$$

$$= 2.34\times10^{28}\,\text{kg}$$

Express m in terms of the mass M_J of Jupiter:

$$\frac{m}{M_J} = \frac{2.34\times10^{28}\,\text{kg}}{1.90\times10^{27}\,\text{kg}} = 12.3$$

or

$$m = \boxed{12.3 M_J}$$

Remarks: A more sophisticated analysis, using the eccentricity of the orbit, leads to a lower bound of 8.7 Jovian masses. (Only a lower bound can be established, as the plane of the orbit is not known.)

13 •••

Picture the Problem We can apply Newton's law of gravity to estimate the maximum angular velocity which the sun can have if it is to stay together and use the definition of angular momentum to find the orbital angular momenta of Jupiter and Saturn. In part (*c*) we can relate the final angular velocity of the sun to its initial angular velocity, its moment of inertia, and the orbital angular momenta of Jupiter and Saturn.

(*a*) Gravity must supply the centripetal force which keeps an element of the sun's mass m rotating around it. Letting the radius of the sun be R, apply Newton's law of gravity to an element of mass m to obtain:

$$m\omega^2 R < \frac{GMm}{R^2}$$

or

$$\omega^2 R < \frac{GM}{R^2}$$

where we've used the inequality because we're estimating the *maximum* angular velocity which the sun can have if it is to stay together.

Solve for ω:

$$\omega < \sqrt{\frac{GM}{R^3}}$$

Substitute numerical values and evaluate ω:

$$\omega < \sqrt{\frac{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(1.99\times10^{30}\ \text{kg})}{(6.96\times10^{8}\ \text{m})^3}} = \boxed{6.28\times10^{-4}\ \text{rad/s}}$$

Calculate the period of this motion from its angular velocity:

$$T = \frac{2\pi}{\omega} = \frac{2\pi}{6.28\times10^{-4}\ \text{rad/s}}$$

$$= 1.00\times10^{4}\ \text{s}\times\frac{1\,\text{h}}{3600\,\text{s}} = \boxed{2.78\,\text{h}}$$

(b) Express the orbital angular momenta of Jupiter and Saturn:

$$L_J = m_J r_J v_J \text{ and } L_S = m_S r_S v_S$$

Express the orbital speeds of Jupiter and Saturn in terms of their periods and distances from the sun:

$$v_J = \frac{2\pi\, r_J}{T_J} \text{ and } v_S = \frac{2\pi\, r_S}{T_S}$$

Substitute to obtain:

$$L_J = \frac{2\pi\, m_J r_J^2}{T_J} \text{ and } L_S = \frac{2\pi\, m_S r_S^2}{T_S}$$

Substitute numerical values and evaluate L_J and L_S:

$$L_J = \frac{2\pi(318M_E)r_J^2}{T_J} = \frac{2\pi(318)(5.98\times10^{24}\ \text{kg})(778\times10^{9}\ \text{m})^2}{11.9\,\text{y}\times\frac{365.25\,\text{d}}{\text{y}}\times\frac{24\,\text{h}}{\text{d}}\times\frac{3600\,\text{s}}{\text{h}}}$$

$$= \boxed{1.93\times10^{43}\ \text{kg}\cdot\text{m}^2/\text{s}}$$

and

$$L_S = \frac{2\pi(95.1M_E)r_S^2}{T_S} = \frac{2\pi(95.1)(5.98\times10^{24}\ \text{kg})(1430\times10^{9}\ \text{m})^2}{29.5\,\text{y}\times\frac{365.25\,\text{d}}{\text{y}}\times\frac{24\,\text{h}}{\text{d}}\times\frac{3600\,\text{s}}{\text{h}}}$$

$$= \boxed{7.85\times10^{42}\ \text{kg}\cdot\text{m}^2/\text{s}}$$

Express the angular momentum of the sun as a fraction of the sum of the angular momenta of Jupiter and Saturn:

$$f = \frac{L_{\text{sun}}}{L_J + L_S}$$

$$= \frac{1.91\times10^{41}\ \text{kg}\cdot\text{m}^2/\text{s}}{(19.3+7.85)\times10^{42}\ \text{kg}\cdot\text{m}^2/\text{s}}$$

$$= \boxed{0.703\%}$$

(*c*) Relate the final angular momentum of the sun to its initial angular momentum and the angular momenta of Jupiter and Saturn:

$$L_f = L_i + L_J + L_S$$

or

$$I_{sun}\omega_f = I_{sun}\omega_i + L_J + L_S$$

Solve for ω_f to obtain:

$$\omega_f = \omega_i + \frac{L_J + L_S}{I_{sun}}$$

Substitute for ω_i and I_{sun}:

$$\omega_f = \frac{2\pi}{T_{sun}} + \frac{L_J + L_S}{0.059 M_{sun} R_{sun}^2}$$

Substitute numerical values and evaluate ω_f:

$$\omega_f = \frac{2\pi}{30\,\text{d} \times \frac{24\,\text{h}}{\text{d}} \times \frac{3600\,\text{s}}{\text{h}}} + \frac{(19.3 + 7.85)\times 10^{42}\ \text{kg}\cdot\text{m}^2/\text{s}}{0.059(1.99\times 10^{30}\ \text{kg})(6.96\times 10^{8}\ \text{m})^2}$$

$$= \boxed{4.80\times 10^{-4}\ \text{rad/s}}$$

Note that this result is about 76% of the maximum possible rotation allowed by gravity that we calculated in part (*a*).

Kepler's Laws

14 •

Picture the Problem We can use the relationship between the semi-major axis and the distances of closest approach and greatest separation, together with Kepler's 3rd law, to find the greatest separation of Alex-Casey from the sun.

Letting x represent the greatest distance from the sun, express the relationship between x, the distance of closest approach, and its semi-major axis R:

$$R = \frac{x + 0.1\,\text{AU}}{2}$$

Solve for x to obtain:

$$x = 2R - 0.1\,\text{AU} \qquad (1)$$

Apply Kepler's 3rd law, with the period T measured in years and R in AU to obtain:

$$T^2 = R^3$$

Solve for R:

$$R = \sqrt[3]{T^2}$$

Substitute numerical values and evaluate R:

$$R = \sqrt[3]{(127.4\,\text{y})^2} = 25.3\,\text{AU}$$

Substitute in equation (1) and evaluate R:

$$x = 2(25.3\,\text{AU}) - 0.1\,\text{AU} = \boxed{50.5\,\text{AU}}$$

15 •

Picture the Problem We can use Kepler's 3rd law to relate the period of Uranus to its mean distance from the sun.

Using Kepler's 3rd law, relate the period of Uranus to its mean distance from the sun:

$$T^2 = Cr^3$$

where $C = \frac{4\pi^2}{GM_s} = 2.973\times10^{-19}\ \text{s}^2/\text{m}^3$.

Solve for T:

$$T = \sqrt{Cr^3}$$

Substitute numerical values and evaluate T:

$$T = \sqrt{\left(2.973\times10^{-19}\ \text{s}^2/\text{m}^3\right)\left(2.87\times10^{12}\ \text{m}\right)^3}$$
$$= 2.651\times10^{9}\ \text{s}\times\frac{1\,\text{h}}{3600\,\text{s}}\times\frac{1\,\text{d}}{24\,\text{h}}\times\frac{1\,\text{y}}{365.25\,\text{d}} = \boxed{84.0\,\text{y}}$$

16 •

Picture the Problem We can use Kepler's 3rd law to relate the period of Hektor to its mean distance from the sun.

Using Kepler's 3rd law, relate the period of Hektor to its mean distance from the sun:

$$T^2 = Cr^3$$

where $C = \frac{4\pi^2}{GM_s} = 2.973\times10^{-19}\ \text{s}^2/\text{m}^3$.

Solve for T:

$$T = \sqrt{Cr^3}$$

Substitute numerical values and evaluate T:

$$T = \sqrt{\left(2.973\times10^{-19}\ \text{s}^2/\text{m}^3\right)\left(5.16\,\text{AU}\times\frac{1.50\times10^{11}\ \text{m}}{\text{AU}}\right)^3}$$
$$= 3.713\times10^{8}\ \text{s}\times\frac{1\,\text{h}}{3600\,\text{s}}\times\frac{1\,\text{d}}{24\,\text{h}}\times\frac{1\,\text{y}}{365.25\,\text{d}} = \boxed{11.8\,\text{y}}$$

17 ••

Picture the Problem Kepler's 3rd law relates the period of Icarus to the length of its semimajor axis. The aphelion distance r_a is related to the perihelion distance r_p and the semimajor axis by $r_a + r_p = 2a$.

(*a*) Using Kepler's 3rd law, relate the period of Icarus to the length of its semimajor axis:

$$T^2 = Ca^3$$

where $C = \frac{4\pi^2}{GM_s} = 2.973\times10^{-19}\ \text{s}^2/\text{m}^3$.

Solve for *a*:

$$a = \sqrt[3]{\frac{T^2}{C}}$$

Substitute numerical values and evaluate *a*:

$$a = \sqrt[3]{\frac{\left(1.1\,\text{y}\times\frac{365.25\,\text{d}}{\text{y}}\times\frac{24\,\text{h}}{\text{d}}\times\frac{3600\,\text{s}}{\text{h}}\right)^2}{2.973\times10^{-19}\ \text{s}^2/\text{m}^3}} = \boxed{1.59\times10^{11}\ \text{m}}$$

(*b*) Use the definition of the eccentricity of an ellipse to determine the perihelion distance of Icarus:

$$r_\text{p} = a(1-e) = \left(1.59\times10^{11}\ \text{m}\right)(1-0.83) = \boxed{2.71\times10^{10}\ \text{m}}$$

Express the relationship between r_p and r_a for an ellipse:

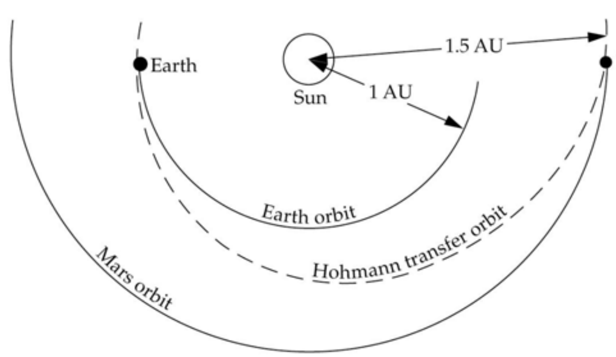
$$r_\text{a} + r_\text{p} = 2a$$

Solve for and evaluate r_a:

$$r_\text{a} = 2a - r_\text{p} = 2\left(1.59\times10^{11}\ \text{m}\right) - 2.71\times10^{10}\ \text{m} = \boxed{2.91\times10^{11}\ \text{m}}$$

18 ••

Picture the Problem The Hohmann transfer orbit is shown in the diagram. We can apply Kepler's 3rd law to relate the time-in-orbit to the period of the spacecraft in its Hohmann Earth-to-Mars orbit. The period of this orbit is, in turn, a function of its semi-major axis which we can find from the average of the lengths of the semi-major axes of the Earth and Mars orbits.



Using Kepler's 3rd law, relate the period T of the spacecraft to the semi-major axis of its orbit:

$$T^2 = R^3$$

Solve for T to obtain:

$$T = \sqrt{R^3}$$

Relate the transit time to the period of this orbit:

$$t_{\text{trip}} = \tfrac{1}{2}T = \tfrac{1}{2}\sqrt{R^3}$$

Express the semi-major axis of the Hohmann transfer orbit in terms of the mean sun-Mars and sun-Earth distances:

$$R = \frac{1.52\,\text{AU} + 1.00\,\text{AU}}{2} = 1.26\,\text{AU}$$

Substitute numerical values and evaluate t_{trip}:

$$t_{\text{trip}} = \tfrac{1}{2}\sqrt{(1.26\,\text{AU})^3}$$
$$= 0.707\,\text{y} \times \frac{365.24\,\text{d}}{1\,\text{y}} = \boxed{258\ \text{d}}$$

***19 ••**

Picture the Problem We can use a property of lines tangent to a circle and radii drawn to the point of contact to show that $b = 90°$. Once we've established that b is a right angle we can use the definition of the sine function to relate the distance from the sun to Venus to the distance from the sun to the earth.

(a) The line from earth to Venus′ orbit is tangent to the orbit of Venus at the point of maximum extension. Venus will appear closer to the sun in earth's sky when it passes the line drawn from earth and tangent to its orbit. Hence:

$$b = \boxed{90°}$$

(b) Using trigonometry, relate the distance from the sun to Venus d_{SV} to the angle a:

$$\sin a = \frac{d_{\text{SV}}}{d_{\text{SE}}}$$

Solve for d_{SV}:

$$d_{\text{SV}} = d_{\text{SE}} \sin a$$

Substitute numerical values and evaluate d_{SV}:

$$d_{\text{SV}} = (1\,\text{AU})\sin 47° = \boxed{0.731\,\text{AU}}$$

Remarks: The correct distance from the sun to Venus is closer to 0.723 AU.

20 ••

Picture the Problem Because the gravitational force the Earth exerts on the moon is along the line joining their centers, the net torque acting on the moon is zero and its angular momentum is conserved in its orbit about the Earth. Because energy is also conserved, we can combine these two expressions to solve for either v_p or v_a initially and then substitute in the conservation of angular momentum equation to find the other.

Letting m be the mass of the moon, apply conservation of angular momentum to the moon at apogee and perigee to obtain:

$$mv_p r_p = mv_a r_a$$

or

$$v_p r_p = v_a r_a$$

Solve for v_a:

$$v_a = \frac{r_p}{r_a} v_p \qquad (1)$$

Apply conservation of energy to the moon-earth system to obtain:

$$\frac{1}{2}mv_p^2 - \frac{GMm}{r_p} = \frac{1}{2}mv_a^2 - \frac{GMm}{r_a}$$

or

$$\frac{1}{2}v_p^2 - \frac{GM}{r_p} = \frac{1}{2}v_a^2 - \frac{GM}{r_a}$$

Substitute for v_a to obtain:

$$\frac{1}{2}v_p^2 - \frac{GM}{r_p} = \frac{1}{2}\left(\frac{r_p}{r_a}v_p\right)^2 - \frac{GM}{r_a} = \frac{1}{2}\left(\frac{r_p}{r_a}\right)^2 v_p^2 - \frac{GM}{r_a}$$

Solve for v_p to obtain:

$$v_p = \sqrt{\frac{2GM}{r_p}\left(\frac{1}{1+r_p/r_a}\right)}$$

Substitute numerical values and evaluate v_p:

$$v_p = \sqrt{\frac{2\left(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(5.98\times10^{24}\ \text{kg}\right)}{3.576\times10^{8}\ \text{m}}\left(\frac{1}{1+\frac{3.576\times10^{8}\ \text{m}}{4.064\times10^{8}\ \text{m}}}\right)} = \boxed{1.09\ \text{km/s}}$$

Substitute numerical values in equation (1) and evaluate v_a:

$$v_a = \frac{3.576\times10^{8}\ \text{m}}{4.064\times10^{8}\ \text{m}}(1.09\ \text{km/s}) = \boxed{0.959\ \text{km/s}}$$

Newton's Law of Gravity

***21** ••

Picture the Problem We can use Kepler's 3rd law to find the mass of Jupiter in part (*a*). In part (*b*) we can express the centripetal accelerations of Europa and Callisto and compare their ratio to the square of the ratio of their distances from the center of Jupiter to show that the given data is consistent with an inverse square law for gravity.

(*a*) Assuming a circular orbit, apply Kepler's 3rd law to the motion of Europa to obtain:

$$T_E^2 = \frac{4\pi^2}{GM_J} R_E^3$$

Solve for the mass of Jupiter:

$$M_J = \frac{4\pi^2}{GT_E^2} R_E^3$$

Substitute numerical values and evaluate M_J:

$$M_J = \frac{4\pi^2}{\left(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)} \times \frac{\left(6.71\times10^8\ \text{m}\right)^3}{\left(3.55\ \text{d}\times\frac{24\ \text{h}}{\text{d}}\times\frac{3600\ \text{s}}{\text{h}}\right)^2}$$

$$= \boxed{1.90\times10^{27}\ \text{kg}}$$, a result in excellent agreement with the accepted value of 1.902×10^{27} kg.

(*b*) Express the centripetal acceleration of both of the moons to obtain:

$$\frac{v^2}{R} = \frac{\left(\frac{2\pi R}{T}\right)^2}{R} = \frac{4\pi^2 R}{T^2}$$

where *R* and *T* are the radii and periods of their motion.

Using this result, express the centripetal accelerations of Europa and Callisto:

$$a_E = \frac{4\pi^2 R_E}{T_E^2} \text{ and } a_C = \frac{4\pi^2 R_C}{T_C^2}$$

Substitute numerical values and evaluate a_E:

$$a_E = \frac{4\pi^2\left(6.71\times10^8\ \text{m}\right)}{\left[(3.55\ \text{d})(24\ \text{h/d})(3600\ \text{s/h})\right]^2} = \boxed{0.282\ \text{m/s}^2}$$

Substitute numerical values and evaluate a_C:

$$a_C = \frac{4\pi^2\left(18.8\times10^8\ \text{m}\right)}{\left[(16.7\ \text{d})(24\ \text{h/d})(3600\ \text{s/h})\right]^2} = \boxed{0.0356\ \text{m/s}^2}$$

Evaluate the ratio of these accelerations:

$$\frac{a_E}{a_C} = \frac{0.282\ \text{m/s}^2}{0.0356\ \text{m/s}^2} = 7.91$$

Evaluate the square of the ratio of the distance of Callisto divided by the distance of Europa to obtain:

$$\left(\frac{R_C}{R_E}\right)^2 = \left(\frac{18.8\times10^8\text{ m}}{6.71\times10^8\text{ m}}\right)^2 = 7.85$$

The close agreement (within 1%) of our last two calculations strongly supports the conclusion that the gravitational force varies inversely with the square of the distance.

***22 •**

Determine the Concept The weight of anything, including astronauts, is the reading of a scale from which the object is suspended or on which it rests. If the scale reads zero, then we say the object is ″weightless.″ The pull of the earth's gravity, on the other hand, depends on the local value of the acceleration of gravity and we can use Newton's law of gravity to find this acceleration at the elevation of the shuttle.

(*a*) Apply Newton's law of gravitation to an astronaut of mass *m* in a shuttle at a distance *h* above the surface of the earth:

$$mg_{\text{shuttle}} = \frac{GmM_E}{(h+R_E)^2}$$

Solve for g_{shuttle}:

$$g_{\text{shuttle}} = \frac{GM_E}{(h+R_E)^2}$$

Substitute numerical values and evaluate g_{shuttle}:

$$g_{\text{shuttle}} = \frac{(6.673\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(5.98\times10^{24}\text{ kg})}{(400\text{ km}+6370\text{ km})^2} = \boxed{8.71\text{ m/s}^2}$$

(*b*) Because they are in "free fall" everything on the shuttle is falling toward the center of the earth with exactly the same acceleration, so the astronauts will seem to be "weightless."

23 •

Picture the Problem We can use Kepler's 3rd law to relate the periods of the moons of Saturn to their mean distances from its center.

(*a*) Using Kepler's 3rd law, relate the period of Mimas to its mean distance from the center of Saturn:

$$T_M^2 = \frac{4\pi^2}{GM_S}r_M^3$$

Solve for T_M:

$$T_M = \sqrt{\frac{4\pi^2}{GM_S}r_M^3}$$

(*b*) Using Kepler's 3rd law, relate the period of Titan to its mean distance from the center of Saturn:

$$T_T^2 = \frac{4\pi^2}{GM_S} r_T^3$$

Substitute numerical values and evaluate T_M:

$$T_M = \sqrt{\frac{4\pi^2 (1.86\times10^8\ \text{m})^3}{(5.69\times10^{26}\ \text{kg})(6.6726\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)}} = \boxed{8.18\times10^4\ \text{s}}$$

Solve for r_T:

$$r_T = \sqrt[3]{\frac{T_T^2 GM_S}{4\pi^2}}$$

Substitute numerical values and evaluate r_T:

$$r_T = \sqrt[3]{\frac{(1.38\times10^6\ \text{s})^2 (6.6726\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(5.69\times10^{26}\ \text{kg})}{4\pi^2}} = \boxed{1.22\times10^9\ \text{m}}$$

24 •

Picture the Problem We can use Kepler's 3rd law to relate the period of the moon to the mass of the earth and the mean earth-moon distance.

(*a*) Using Kepler's 3rd law, relate the period of the moon to its mean orbital radius:

$$T_m^2 = \frac{4\pi^2}{GM_E} r_m^3$$

Solve for M_E:

$$M_E = \frac{4\pi^2}{GT_m^2} r_m^3$$

Substitute numerical values and evaluate M_E:

$$M_E = \frac{4\pi^2 (3.84\times10^8\ \text{m})^3}{(6.6726\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)\left(27.3\,\text{d}\times\frac{24\,\text{h}}{\text{d}}\times\frac{3600\ \text{s}}{\text{h}}\right)^2} = \boxed{6.02\times10^{24}\ \text{kg}}$$

Remarks: This analysis neglects the mass of the moon; consequently the mass calculated here is slightly too great.

25 •

Picture the Problem We can use Kepler's 3rd law to relate the period of the earth to the mass of the sun and the mean earth-sun distance.

(*a*) Using Kepler's 3rd law, relate the period of the earth to its mean orbital radius:

$$T_E^2 = \frac{4\pi^2}{GM_S} r_E^3$$

Solve for M_S:

$$M_S = \frac{4\pi^2}{GT_E^2} r_E^3$$

Substitute numerical values and evaluate M_S:

$$M_S = \frac{4\pi^2 \left(1.496\times10^{11}\text{ m}\right)^3}{\left(6.6726\times10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2\right)\left(1\text{ y}\times\frac{365.25\text{ d}}{\text{y}}\times\frac{24\text{ h}}{\text{d}}\times\frac{3600\text{ s}}{\text{h}}\right)^2}$$

$$= \boxed{1.99\times10^{30}\text{ kg}}$$

***26 •**

Picture the Problem We can relate the acceleration of an object at any elevation to its acceleration at the surface of the earth through the law of gravity and Newton's 2nd law of motion.

Letting a represent the acceleration due to gravity at this altitude (R_E) and m the mass of the object, apply Newton's 2nd law and the law of gravity to obtain:

$$\sum F_{\text{radial}} = \frac{GmM_E}{(2R_E)^2} = ma$$

and

$$a = \frac{GM_E}{(2R_E)^2} \qquad (1)$$

Apply Newton's 2nd law to the same object when it is at the surface of the earth:

$$\sum F_{\text{radial}} = \frac{GmM_E}{R_E^2} = mg$$

and

$$g = \frac{GM_E}{R_E^2} \qquad (2)$$

Divide equation (1) by equation (2) and solve for a:

$$\frac{a}{g} = \frac{R_E^2}{4R_E^2}$$

and

$$a = \tfrac{1}{4}g = \tfrac{1}{4}\left(9.81\text{ m/s}^2\right) = \boxed{2.45\text{ m/s}^2}$$

27 •

Picture the Problem Your weight is the local gravitational force exerted on you. We can use the definition of density to relate the mass of the planet to the mass of earth and the law of gravity to relate your weight on the planet to your weight on earth.

Using the definition of density, relate the mass of the earth to its radius:

$$M_E = \rho V_E = \tfrac{4}{3}\rho\pi R_E^3$$

Relate the mass of the planet to its radius:

$$M_P = \rho V_P = \tfrac{4}{3}\rho\pi R_P^3 = \tfrac{4}{3}\rho\pi(10R_E)^3$$

Divide the second of these equations by the first to express M_P in terms of M_E:

$$\frac{M_P}{M_E} = \rho\frac{\tfrac{4}{3}\rho\pi(10R_E)^3}{\tfrac{4}{3}\rho\pi R_E^3}$$

and

$$M_P = 10^3 M_E$$

Letting w' represent your weight on the planet, use the law of gravity to relate w' to your weight on earth:

$$w' = \frac{GmM_P}{R_P^2} = \frac{Gm(10^3 M_E)}{(10R_E)^2} = 10\frac{GmM_E}{R_E^2} = \boxed{10w}$$

where w is your weight on earth.

28 •

Picture the Problem We can relate the acceleration due to gravity of a test object at the surface of the new planet to the acceleration due to gravity at the surface of the earth through use of the law of gravity and Newton's 2nd law of motion.

Letting a represent the acceleration due to gravity at the surface of this new planet and m the mass of a test object, apply Newton's 2nd law and the law of gravity to obtain:

$$\sum F_{\text{radial}} = \frac{GmM_E}{\left(\tfrac{1}{2}R_E\right)^2} = ma$$

and

$$a = \frac{GM_E}{\left(\tfrac{1}{2}R_E\right)^2}$$

Simplify this expression to obtain:

$$a = 4\frac{GM_E}{R_E^2} = 4g = \boxed{39.2\,\text{m/s}^2}$$

29 •

Picture the Problem We can use conservation of angular momentum to relate the planet's speeds at aphelion and perihelion.

Using conservation of angular

$$L_a = L_p$$

momentum, relate the angular momenta of the planet at aphelion and perihelion:

or

$$mv_p r_p = mv_a r_a$$

Solve for the planet's speed at aphelion:

$$v_a = \frac{v_p r_p}{r_a}$$

Substitute numerical values and evaluate v_a:

$$v_a = \frac{(5\times10^4\ \text{m/s})(1.0\times10^{15}\ \text{m})}{2.2\times10^{15}\ \text{m}} = \boxed{2.27\times10^4\ \text{m/s}}$$

30 •

Picture the Problem We can use Newton's law of gravity to express the gravitational force acting on an object at the surface of the neutron star in terms of the weight of the object. We can then simplify this expression be dividing out the mass of the object … leaving an expression for the acceleration due to gravity at the surface of the neutron star.

Apply Newton's law of gravity to an object of mass m at the surface of the neutron star to obtain:

$$\frac{GM_{\text{Neutron Star}}m}{R^2_{\text{Neutron Star}}} = mg$$

where g represents the acceleration due to gravity at the surface of the neutron star.

Solve for g and substitute for the mass of the neutron star:

$$g = \frac{GM_{\text{Neutron Star}}}{R^2_{\text{Neutron Star}}} = \frac{G(1.60M_{\text{sun}})}{R^2_{\text{Neutron Star}}}$$

Substitute numerical values and evaluate g:

$$g = \frac{1.60(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(1.99\times10^{30}\ \text{kg})}{(10.5\ \text{km})^2} = \boxed{1.93\times10^{12}\ \text{m/s}^2}$$

***31** ••

Picture the Problem We can use conservation of angular momentum to relate the asteroid's aphelion and perihelion distances.

Using conservation of angular momentum, relate the angular momenta of the asteroid at aphelion and perihelion:

$$L_a = L_p$$

or

$$mv_p r_p = mv_a r_a$$

Solve for and evaluate the ratio of the asteroid's aphelion and perihelion distances:

$$\frac{r_a}{r_p} = \frac{v_p}{v_a} = \frac{20\,\text{km/s}}{14\,\text{km/s}} = \boxed{1.43}$$

32 ••

Picture the Problem We'll use the law of gravity to find the gravitational force acting on the satellite. The application of Newton's 2nd law will lead us to the speed of the satellite and its period can be found from its definition.

(*a*) Letting *m* represent the mass of the satellite and *h* its elevation, use the law of gravity to express the gravitational force acting on it:

$$F_g = \frac{GmM_E}{(R_E + h)^2} = \frac{mR_E^2 g}{(R_E + h)^2} = \frac{mg}{\left(1 + \frac{h}{R_E}\right)^2}$$

Substitute numerical values and evaluate F_g:

$$F_g = \frac{mg}{\left(1 + \frac{h}{R_E}\right)^2} = \frac{(300\,\text{kg})(9.81\,\text{N/kg})}{\left(1 + \frac{5\times10^7\,\text{m}}{6.37\times10^6\,\text{m}}\right)^2} = \boxed{37.6\,\text{N}}$$

(*b*) Using Newton's 2nd law, relate the gravitational force acting on the satellite to its centripetal acceleration:

$$F_g = m\frac{v^2}{r}$$

Solve for *v*:

$$v = \sqrt{\frac{F_g r}{m}}$$

Substitute numerical values and evaluate *v*:

$$v = \sqrt{\frac{(37.6\,\text{N})(6.37\times10^6\,\text{m} + 5\times10^7\,\text{m})}{300\,\text{kg}}} = \boxed{2.66\ \text{km/s}}$$

(*c*) Express the period of the satellite:

$$T = \frac{2\pi r}{v}$$

Substitute numerical values and evaluate *T*:

$$T = \frac{2\pi(6.37\times10^6\,\text{m} + 5\times10^7\,\text{m})}{2.66\times10^3\,\text{m/s}} = 1.33\times10^5\,\text{s}\times\frac{1\,\text{h}}{3600\,\text{s}} = \boxed{36.9\,\text{h}}$$

***33 ••**

Picture the Problem We can determine the maximum range at which an object with a given mass can be detected by substituting the equation for the gravitational field in the expression for the resolution of the meter and solving for the distance. Differentiating $g(r)$ with respect to r, separating variables to obtain dg/g, and approximating Δr with dr will allow us to determine the vertical change in the position of the gravity meter in the earth's gravitational field is detectable.

(*a*) Express the gravitational field of the earth:

$$g_E = \frac{GM_E}{R_E^2}$$

Express the gravitational field due to the mass m (assumed to be a point mass) of your friend and relate it to the resolution of the meter:

$$g(r) = \frac{Gm}{r^2} = 10^{-11} g_E = 10^{-11}\frac{GM_E}{R_E^2}$$

Solve for r:

$$r = R_E\sqrt{\frac{10^{11} m}{M_E}}$$

Substitute numerical values and evaluate r:

$$r = \left(6.37\times10^6\ \text{m}\right)\sqrt{\frac{10^{11}(80\ \text{kg})}{5.98\times10^{24}\ \text{kg}}} = \boxed{7.37\ \text{m}}$$

(*b*) Differentiate $g(r)$ and simplify to obtain:

$$\frac{dg}{dr} = \frac{-2Gm}{r^3} = -\frac{2}{r}\left(\frac{Gm}{r^2}\right) = -\frac{2}{r}g$$

Separate variables to obtain:

$$\frac{dg}{g} = -2\frac{dr}{r} = 10^{-11}$$

Approximating dr with Δr, evaluate Δr with $r = R_E$:

$$\Delta r = \left|-\tfrac{1}{2}\left(10^{-11}\right)\left(6.37\times10^6\ \text{m}\right)\right| = 3.19\times10^{-5}\ \text{m} = \boxed{0.0319\ \text{mm}}$$

34 ••

Picture the Problem We can use the law of gravity and Newton's 2nd law to relate the force exerted on the planet by the star to its orbital speed and the definition of the period to relate it to the radius of the orbit.

Using the law of gravity and Newton's 2nd law, relate the force exerted on the planet by the star to its centripetal acceleration:

$$F_{\text{net}} = \frac{KMm}{r} = m\frac{v^2}{r}$$

Solve for v^2 to obtain:

$$v^2 = KM$$

Express the period of the planet:

$$T = \frac{2\pi r}{v} = \frac{2\pi r}{\sqrt{KM}} = \frac{2\pi}{\sqrt{KM}} r$$

or

$$\boxed{T \propto r}$$

***35 ••**

Picture the Problem We can use the definitions of the gravitational fields at the surfaces of the earth and the moon to express the accelerations due to gravity at these locations in terms of the average densities of the earth and the moon. Expressing the ratio of these accelerations will lead us to the ratio of the densities.

Express the acceleration due to gravity at the surface of the earth in terms of the earth's average density:

$$g_{\text{E}} = \frac{GM_{\text{E}}}{R_{\text{E}}^2} = \frac{G\rho_{\text{E}}V_{\text{E}}}{R_{\text{E}}^2} = \frac{G\rho_{\text{E}}\,\frac{4}{3}\pi R_{\text{E}}^3}{R_{\text{E}}^2}$$
$$= \tfrac{4}{3}G\rho_{\text{E}}\pi R_{\text{E}}$$

Express the acceleration due to gravity at the surface of the moon in terms of the moon's average density:

$$g_{\text{M}} = \tfrac{4}{3}G\rho_{\text{M}}\pi R_{\text{M}}$$

Divide the second of these equations by the first to obtain:

$$\frac{g_{\text{M}}}{g_{\text{E}}} = \frac{\rho_{\text{M}}\,R_{\text{M}}}{\rho_{\text{E}}\,R_{\text{E}}}$$

Solve for $\frac{\rho_{\text{M}}}{\rho_{\text{E}}}$:

$$\frac{\rho_{\text{M}}}{\rho_{\text{E}}} = \frac{g_{\text{M}}R_{\text{E}}}{g_{\text{E}}R_{\text{M}}}$$

Substitute numerical values and evaluate $\frac{\rho_{\text{M}}}{\rho_{\text{E}}}$:

$$\frac{\rho_{\text{M}}}{\rho_{\text{E}}} = \frac{(1.62\,\text{m/s}^2)(6.37\times10^6\,\text{m})}{(9.81\,\text{m/s}^2)(1.738\times10^6\,\text{m})}$$
$$= \boxed{0.605}$$

Measurement of G

36 •

Picture the Problem We can use the law of gravity to find the forces of attraction between the two masses and the definition of torque to determine the balancing torque required.

(*a*) Use the law of gravity to express the force of attraction between the two masses:

$$F=\frac{Gm_1m_2}{r^2}$$

Substitute numerical values and evaluate *F*:

$$F=\frac{\left(6.6726\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(10\,\text{kg}\right)\left(0.01\,\text{kg}\right)}{\left(0.06\,\text{m}\right)^2}=\boxed{1.85\times10^{-9}\ \text{N}}$$

(*b*) Use its definition to find the torque exerted by the suspension to balance these forces:

$$\tau=2Fr=2\left(1.85\times10^{-9}\ \text{N}\right)\left(0.1\,\text{m}\right)=\boxed{3.70\times10^{-10}\ \text{N}\cdot\text{m}}$$

Gravitational and Inertial Mass

37 •

Picture the Problem Newton's 2nd law of motion relates the masses and accelerations of these objects to their common accelerating force.

(*a*) Apply Newton's 2nd law to the standard object:

$$F=m_1a_1$$

Apply Newton's 2nd law to the object of unknown mass:

$$F=m_2a_2$$

Eliminate *F* between these two equations and solve for m_2:

$$m_2=\frac{a_1}{a_2}m_1$$

Substitute numerical values and evaluate m_2:

$$m_2=\frac{2.6587\,\text{m/s}^2}{1.1705\,\text{m/s}^2}\left(1\,\text{kg}\right)=\boxed{2.27\,\text{kg}}$$

(*b*)

$$\boxed{\text{It is the } \textit{inertial} \text{ mass of } m_2.}$$

38 •

Picture the Problem Newton's 2nd law of motion relates the weights of these two objects to their masses and the acceleration due to gravity.

(*a*) Apply Newton's 2nd law to the standard object:

$$F_{net} = w_1 = m_1 g$$

Apply Newton's 2nd law to the object of unknown mass:

$$F_{net} = w_2 = m_2 g$$

Eliminate *g* between these two equations and solve for m_2:

$$m_2 = \frac{w_2}{w_1} m_1$$

Substitute numerical values and evaluate m_2:

$$m_2 = \frac{56.6\text{ N}}{9.81\text{ N}}(1\text{ kg}) = \boxed{5.77\text{ kg}}$$

(*b*) Since this result is determined by the effect on m_2 of the earth's gravitational field, it is the *gravitational* mass of m_2.

***39** •

Picture the Problem Noting that $g_1 \sim g_2 \sim g$, let the acceleration of gravity on the first object be g_1, and on the second be g_2. We can use a constant-acceleration equation to express the difference in the distances fallen by each object and then relate the average distance fallen by the two objects to obtain an expression from which we can approximate the distance they would have to fall before we might measure a difference in their fall distances greater than 1 mm.

Express the difference Δd in the distances fallen by the two objects in time *t*:

$$\Delta d = d_1 - d_2$$

Express the distances fallen by each of the objects in time *t*:

$$d_1 = \tfrac{1}{2} g_1 t^2$$

and

$$d_2 = \tfrac{1}{2} g_2 t^2$$

Substitute to obtain:

$$\Delta d = \tfrac{1}{2} g_1 t^2 - \tfrac{1}{2} g_2 t^2 = \tfrac{1}{2}(g_1 - g_2)\, t^2$$

Relate the average distance *d* fallen by the two objects to their time of fall:

$$d = \tfrac{1}{2} g t^2$$

or

$$t^2 = \frac{2d}{g}$$

Substitute to obtain:

$$\Delta d \approx \tfrac{1}{2}\Delta g \frac{2d}{g} = d\frac{\Delta g}{g}$$

Solve for d to obtain:

$$d = \Delta d \frac{g}{\Delta g}$$

Substitute numerical values and evaluate d:

$$d = \left(10^{-3}\text{ m}\right)\left(10^{12}\right) = \boxed{10^{9}\text{ m}}$$

Gravitational Potential Energy

40 •

Picture the Problem Choosing the zero of gravitational potential energy to be at infinite separation yields, as the potential energy of a two-body system in which the objects are separated by a distance r, $U(r) = -GMm/r$, where M and m are the masses of the two bodies. In order for an object to just escape a gravitational field from a particular location, it must have enough kinetic energy so that its total energy is zero.

(*a*) Letting $U(\infty) = 0$, express the gravitational potential energy of the earth-object system:

$$U(r) = -\frac{GM_{\text{E}}m}{r} \qquad (1)$$

Substitute for GM_{E} and simplify to obtain:

$$U(R_{\text{E}}) = -\frac{GM_{\text{E}}m}{R_{\text{E}}} = -\frac{gR_{\text{E}}^2 m}{R_{\text{E}}} = -mgR_{\text{E}}$$

Substitute numerical values and evaluate $U(R_{\text{E}})$:

$$U(R_{\text{E}}) = -(100\,\text{kg})(9.81\,\text{N/kg})\left(6.37\times10^{6}\text{ m}\right) = \boxed{-6.25\times10^{9}\text{ J}}$$

(*b*) Evaluate equation (1) with $r = 2R_{\text{E}}$:

$$U(2R_{\text{E}}) = -\frac{GM_{\text{E}}m}{2R_{\text{E}}} = -\frac{gR_{\text{E}}^2 m}{2R_{\text{E}}} = -\tfrac{1}{2}mgR_{\text{E}}$$

Substitute numerical values and evaluate $U(2R_{\text{E}})$:

$$U(2R_{\text{E}}) = -\tfrac{1}{2}(100\,\text{kg})(9.81\,\text{N/kg})\left(6.37\times10^{6}\text{ m}\right) = \boxed{-3.12\times10^{9}\text{ J}}$$

(*c*) Express the condition that an object must satisfy in order to escape from the earth's gravitational

$$K_{\text{esc}}(2R_{\text{E}}) + U(2R_{\text{E}}) = 0$$

or

$$\tfrac{1}{2}mv_{\text{esc}}^2 + U(2R_{\text{E}}) = 0$$

field from a height R_E above its surface:

Solve for v_{esc}:

$$v_{esc} = \sqrt{\frac{-2U(2R_E)}{m}}$$

Substitute numerical values and evaluate v_{esc}:

$$v_{esc} = \sqrt{\frac{-2(-3.12\times10^9\ \text{J})}{100\,\text{kg}}} = \boxed{7.90\,\text{km/s}}$$

41 •

Picture the Problem In order for an object to just escape a gravitational field from a particular location, an amount of work must be done on it that is equal to its potential energy in its initial position.

Express the work needed to remove the point mass from the surface of the sphere to a point a very large distance away:

$$W = \Delta U = U_f - U_i$$

or, because $U_f = 0$,

$$W = \Delta U = -U_i \qquad (1)$$

Express the initial potential energy of the system:

$$U_i = -\frac{GMm_0}{R}$$

Substitute in equation (1) to obtain:

$$W = \boxed{\frac{GMm_0}{R}}$$

42 •

Picture the Problem Let the zero of gravitational potential energy be at infinity and let m represent the mass of the spacecraft. We'll use conservation of energy to relate the initial kinetic and potential energies to the final potential energy of the earth-spacecraft system.

Use conservation of energy to relate the initial kinetic and potential energies of the system to its final energy when the spacecraft is one earth radius above the surface of the planet:

$$K_f - K_i + U_f - U_i = 0$$

or, because $K_f = 0$,

$$-K(R_E) + U(2R_E) - U(R_E) = 0 \qquad (1)$$

Express the potential energy of the spacecraft-and-earth system when the spacecraft is at a distance r from the surface of the earth:

$$U(r) = -\frac{GM_{\text{E}}m}{r}$$

Substitute in equation (1) to obtain:

$$-\tfrac{1}{2}mv^2 - \frac{GM_{\text{E}}m}{2R_{\text{E}}} + \frac{GM_{\text{E}}m}{R_{\text{E}}} = 0$$

Solve for v:

$$v = \sqrt{\frac{GM_{\text{E}}}{R_{\text{E}}}} = \sqrt{\frac{gR_{\text{E}}^2}{R_{\text{E}}}} = \sqrt{gR_{\text{E}}}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{(9.81\,\text{m/s}^2)(6.37\times10^6\,\text{m})} = \boxed{7.91\,\text{km/s}}$$

***43 ••**

Picture the Problem Let the zero of gravitational potential energy be at infinity and let m represent the mass of the object. We'll use conservation of energy to relate the initial potential energy of the object-earth system to the final potential and kinetic energies.

Use conservation of energy to relate the initial potential energy of the system to its energy as the object is about to strike the earth:

$$K_{\text{f}} - K_{\text{i}} + U_{\text{f}} - U_{\text{i}} = 0$$

or, because $K_{\text{i}} = 0$,

$$K(R_{\text{E}}) + U(R_{\text{E}}) - U(R_{\text{E}} + h) = 0 \quad (1)$$

where h is the initial height above the earth's surface.

Express the potential energy of the object-earth system when the object is at a distance r from the surface of the earth:

$$U(r) = -\frac{GM_{\text{E}}m}{r}$$

Substitute in equation (1) to obtain:

$$\tfrac{1}{2}mv^2 - \frac{GM_{\text{E}}m}{R_{\text{E}}} + \frac{GM_{\text{E}}m}{R_{\text{E}} + h} = 0$$

Solve for v:

$$v = \sqrt{2\left(\frac{GM_{\text{E}}}{R_{\text{E}}} - \frac{GM_{\text{E}}}{R_{\text{E}} + h}\right)} = \sqrt{2gR_{\text{E}}\left(\frac{h}{R_{\text{E}} + h}\right)}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{\frac{2(9.81\,\text{m/s}^2)(6.37\times10^6\,\text{m})(4\times10^6\,\text{m})}{6.37\times10^6\,\text{m} + 4\times10^6\,\text{m}}} = \boxed{6.94\,\text{km/s}}$$

44 ••

Picture the Problem Let the zero of gravitational potential energy be at infinity, *m* represent the mass of the object, and *h* the maximum height reached by the object. We'll use conservation of energy to relate the initial potential and kinetic energies of the object-earth system to the final potential energy.

Use conservation of energy to relate the initial potential energy of the system to its energy as the object is about to strike the earth:

$$K_f - K_i + U_f - U_i = 0$$

or, because $K_f = 0$,

$$K(R_E) + U(R_E) - U(R_E + h) = 0 \quad (1)$$

where h is the initial height above the earth's surface.

Express the potential energy of the object-earth system when the object is at a distance r from the surface of the earth:

$$U(r) = -\frac{GM_E m}{r}$$

Substitute in equation (1) to obtain:

$$\tfrac{1}{2}mv^2 - \frac{GM_E m}{R_E} + \frac{GM_E m}{R_E + h} = 0$$

Solve for h:

$$h = \frac{R_E}{\dfrac{2gR_E}{v^2} - 1}$$

Substitute numerical values and evaluate h:

$$h = \frac{6.37\times10^6\,\text{m}}{\dfrac{2(9.81\,\text{m/s}^2)(6.37\times10^6\,\text{m})}{(4\times10^3\,\text{m})^2} - 1} = \boxed{935\,\text{km}}$$

45 ••

Picture the Problem When the point mass is inside the spherical shell, there is no mass between it and the center of the shell. On the other hand, when the point mass is outside the spherical shell we can use the law of gravity to express the force acting on it. In (*b*) we can derive $U(r)$ from $F(r)$.

(*a*) The force exerted by the shell on a point mass m_0 when m_0 is inside the shell is:

$$\vec{F}_{\text{inside}} = \boxed{0}$$

The force exerted by the shell on a point mass m_0 when m_0 is outside the shell is:

$$\vec{F}_{\text{outside}} = m_0\vec{g} = \boxed{-\frac{GMm_0}{r^2}\hat{r}}$$

where $\hat{r}$ is radially outward from the center of the spherical shell.

(*b*) Use its definition to express $U(r)$ for $r > R$:

$$U(r) = -\int_\infty^r F_r dr = GMm_0\int_\infty^r r^{-2}dr$$

$$= \boxed{-\frac{GMm_0}{r}}$$

When $r = R$:

$$U(R) = \boxed{-\frac{GMm_0}{R}}$$

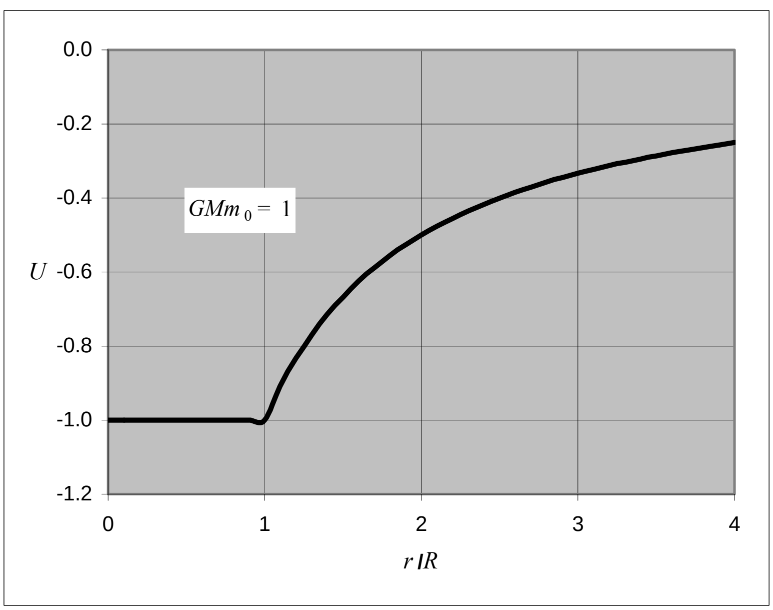
(*c*) For $r < R$, $F = 0$ and:

$$\frac{dU}{dr} = 0 \Rightarrow \boxed{U = \text{constant}}$$

(*d*) Because U is continuous, then for $r < R$:

$$U(r) = U(R) = \boxed{-\frac{GMm_0}{R}}$$

(*e*) A sketch of U as a function of r/R (with $GMm_0 = 1$) is shown below:



46 •

Picture the Problem The escape speed from a planet is related to its mass according to $v_e = \sqrt{2GM/R}$, where M and R represent the mass and radius of the planet, respectively.

Express the escape speed from Saturn:

$$v_{e,S} = \sqrt{\frac{2GM_S}{R_S}} \qquad (1)$$

Express the escape speed from Earth:

$$v_{e,E} = \sqrt{\frac{2GM_E}{R_E}} \qquad (2)$$

Divide equation (1) by equation (2) to obtain:

$$\frac{v_{e,S}}{v_{e,E}} = \frac{\sqrt{\frac{2GM_S}{R_S}}}{\sqrt{\frac{2GM_E}{R_E}}} = \sqrt{\frac{R_E}{R_S} \cdot \frac{M_S}{M_E}}$$

Substitute numerical values and evaluate $\frac{v_{e,S}}{v_{e,E}}$:

$$\frac{v_{e,S}}{v_{e,E}} = \sqrt{\frac{1}{9.47} \times \frac{95.2}{1}} = 3.17$$

Solve for and evaluate $v_{e,S}$:

$$v_{e,S} = 3.17 v_{e,E} = 3.17(11.2\,\text{km/s}) = \boxed{35.5\,\text{km/s}}$$

47 •

Picture the Problem The escape speed from the moon or the earth is given by $v_e = \sqrt{2GM/R}$, where M and R represent the masses and radii of the moon or the earth.

Express the escape speed from the moon:

$$v_{e,S} = \sqrt{\frac{2GM_m}{R_m}} = \sqrt{2g_m R_m} \qquad (1)$$

Express the escape speed from earth:

$$v_{e,E} = \sqrt{\frac{2GM_E}{R_E}} = \sqrt{2g_E R_E} \qquad (2)$$

Divide equation (1) by equation (2) to obtain:

$$\frac{v_{e,m}}{v_{e,E}} = \frac{\sqrt{g_m R_m}}{\sqrt{g_E R_E}} = \sqrt{\frac{g_m R_m}{g_E R_E}}$$

Solve for $v_{e,m}$:

$$v_{\text{e.m}} = \sqrt{\frac{g_{\text{m}} R_{\text{m}}}{g_{\text{E}} R_{\text{E}}}} v_{\text{e.E}}$$

Substitute numerical values and evaluate $v_{e,m}$:

$$v_{\text{e.m}} = \sqrt{(0.166)(0.273)}(11.2\,\text{km/s}) = \boxed{2.38\,\text{km/s}}$$

***48** •

Picture the Problem We'll consider a rocket of mass *m* which is initially on the surface of the earth (mass *M* and radius *R*) and compare the kinetic energy needed to get the rocket to its escape velocity with its kinetic energy in a low circular orbit around the earth. We can use conservation of energy to find the escape kinetic energy and Newton's law of gravity to derive an expression for the low earth-orbit kinetic energy.

Apply conservation of energy to relate the initial energy of the rocket to its escape kinetic energy:

$$K_{\text{f}} - K_{\text{i}} + U_{\text{f}} - U_{\text{i}} = 0$$

Letting the zero of gravitational potential energy be at infinity we have $U_f = K_f = 0$ and:

$$-K_{\text{i}} - U_{\text{i}} = 0$$

or

$$K_{\text{e}} = -U_{\text{i}} = \frac{GMm}{R}$$

Apply Newton's law of gravity to the rocket in orbit at the surface of the earth to obtain:

$$\frac{GMm}{R^2} = m\frac{v^2}{R}$$

Rewrite this equation to express the low-orbit kinetic energy E_o of the rocket:

$$K_{\text{o}} = \tfrac{1}{2}mv^2 = \frac{GMm}{2R}$$

Express the ratio of K_o to K_e:

$$\frac{K_{\text{o}}}{K_{\text{e}}} = \frac{\frac{GMm}{2R}}{\frac{GMm}{R}} = \frac{1}{2} \Rightarrow K_{\text{e}} = \boxed{2K_{\text{o}}}$$, as asserted by Heinlein.

49 ••

Picture the Problem Let the zero of gravitational potential energy be at infinity, *m* represent the mass of the particle, and the subscript E refer to the earth. When the particle is very far from the earth, the gravitational potential energy of the earth-particle system will be zero. We'll use conservation of energy to relate the initial potential and kinetic energies of the particle-earth system to the final kinetic energy of the particle.

Use conservation of energy to relate the initial energy of the system to its energy when the particle is very

$$K_{\text{f}} - K_{\text{i}} + U_{\text{f}} - U_{\text{i}} = 0$$

or, because $U_f = 0$,

$$K(\infty) - K(R_{\text{E}}) - U(R_{\text{E}}) = 0 \qquad (1)$$

from the earth:

Substitute in equation (1) to obtain:

$$\tfrac{1}{2}mv_\infty^2 - \tfrac{1}{2}m(2v_e)^2 + \frac{GM_E m}{R_E} = 0$$

or, because $GM_E = gR_E^2$,

$$\tfrac{1}{2}mv_\infty^2 - \tfrac{1}{2}mv^2 + mgR_E = 0$$

Solve for v_∞:

$$v_\infty = \sqrt{2\left(2v_e^2 - gR_E\right)}$$

Substitute numerical values and evaluate v_∞:

$$v_\infty = \sqrt{2\left[2\left(11.2\times10^3\ \text{m/s}\right)^2 - \left(9.81\,\text{m/s}^2\right)\left(6.37\times10^6\ \text{m}\right)\right]} = \boxed{19.4\,\text{km/s}}$$

50 ••

Picture the Problem Let the zero of gravitational potential energy be at infinity, *m* represent the mass of the particle, and the subscript E refer to the earth. When the particle is very far from the earth, the gravitational potential energy of the earth-particle system will be zero. We'll use conservation of energy to relate the initial potential and kinetic energies of the particle-earth system to the final kinetic energy of the particle.

Use conservation of energy to relate the initial energy of the system to its energy when the particle is very far away:

$$K_f - K_i + U_f - U_i = 0$$

or, because $U_f = 0$,

$$K(\infty) - K(R_E) - U(R_E) = 0 \qquad (1)$$

Substitute in equation (1) to obtain:

$$\tfrac{1}{2}mv_\infty^2 - \tfrac{1}{2}mv_i^2 + \frac{GM_E m}{R_E} = 0$$

or, because $GM_E = gR_E^2$,

$$\tfrac{1}{2}mv_\infty^2 - \tfrac{1}{2}mv_i^2 + mgR_E = 0$$

Solve for v_i:

$$v_i = \sqrt{v_\infty^2 + 2gR_E}$$

Substitute numerical values and evaluate v_i:

$$v_i = \sqrt{\left(11.2\times10^3\ \text{m/s}\right)^2 + 2\left(9.81\,\text{m/s}^2\right)\left(6.37\times10^6\ \text{m}\right)} = \boxed{15.8\,\text{km/s}}$$

51 ••

Picture the Problem We can use the definition of kinetic energy to find the energy necessary to launch a 1-kg object from the earth at escape speed.

(*a*) Using the definition of kinetic energy, find the energy required to launch a 1-kg object from the surface of the earth at escape speed:

$$K = \tfrac{1}{2}mv_e^2$$
$$= \tfrac{1}{2}(1\,\text{kg})(11.2\times10^3\ \text{m/s})^2$$
$$= \boxed{62.7\,\text{MJ}}$$

(*b*) Using the conversion factor 1 kW·h = 3.6 MJ, convert 62.7 MJ to kW·h:

$$K = 62.7\,\text{MJ}\times\frac{1\,\text{kW}\cdot\text{h}}{3.6\,\text{MJ}}$$
$$= \boxed{17.4\,\text{kW}\cdot\text{h}}$$

(*c*) Express the cost of this project in terms of the mass of the astronaut:

$$\text{Cost} = \text{rate}\times\frac{\text{required energy}}{\text{kg}}\times\text{mass}$$

Substitute numerical values and find the cost:

$$\text{Cost} = \frac{\$0.10}{\text{kW}\cdot\text{h}}\times\frac{17.4\,\text{kW}\cdot\text{h}}{\text{kg}}(80\,\text{kg})$$
$$= \boxed{\$139}$$

52 ••

Picture the Problem Let *m* represent the mass of the body that is projected vertically from the surface of the earth. We'll begin by using conservation of energy under the assumption that the gravitational field is constant to determine H'. We'll apply conservation of energy a second time, with the zero of gravitational potential energy at infinity, to express *H*. Finally, we'll solve these two equations simultaneously to express *H* in terms of H'.

Assuming the gravitational field to be constant and letting the zero of potential energy be at the surface of the earth, apply conservation of energy to relate the initial kinetic energy and the final potential energy of the object-earth system:

$$K_f - K_i + U_f - U_i = 0$$

or, because $K_f = U_i = 0$,

$$-K_i + U_f = 0$$

Substitute for K_i and U_f and solve for H':

$$-\tfrac{1}{2}mv^2 + mgH' = 0$$

and

$$H' = \frac{v^2}{2g} \qquad (1)$$

Letting the zero of gravitational potential energy be at infinity, use conservation of energy to relate the initial kinetic energy and the final

$$K_f - K_i + U_f - U_i = 0$$

or, because $K_f = 0$,

$$-K_i + U_f - U_i = 0$$

potential energy of the object-earth system:

Substitute to obtain:

$$-\tfrac{1}{2}mv^2 - \frac{GMm}{R_E + H} + \frac{GMm}{R_E} = 0$$

or

$$-\tfrac{1}{2}v^2 - \frac{gR_E^2}{R_E + H} + \frac{gR_E^2}{R_E} = 0$$

Solve for v^2:

$$v^2 = 2gR_E^2\left(\frac{1}{R_E} - \frac{1}{R_E + H}\right) = 2gR_E\left(\frac{H}{R_E + H}\right)$$

Substitute in equation (1) to obtain:

$$H' = R_E\left(\frac{H}{R_E + H}\right)$$

Solve for H:

$$H = \boxed{\frac{H'R_E}{R_E - H'}}$$

Orbits

53 ••

Picture the Problem We can use its definition to express the period of the spacecraft's motion and apply Newton's 2nd law to the spacecraft to determine its orbital velocity. We can then use this orbital velocity to calculate the kinetic energy of the spacecraft. We can relate the spacecraft's angular momentum to its kinetic energy and moment of inertia.

(*a*) Express the period of the spacecraft's orbit about the earth:

$$T = \frac{2\pi R}{v} = \frac{2\pi(3R_E)}{v} = \frac{6\pi R_E}{v}$$

where v is the orbital speed of the spacecraft.

Use Newton's 2nd law to relate the gravitational force acting on the spacecraft to its orbital speed:

$$F_{radial} = \frac{GM_E m}{(3R_E)^2} = m\frac{v^2}{3R_E}$$

Solve for v to obtain:

$$v = \sqrt{\frac{gR_E}{3}}$$

Substitute for v in our expression for T to obtain:

$$T = 6\sqrt{3}\pi\sqrt{\frac{R_E}{g}}$$

Substitute numerical values and evaluate T:

$$T = 6\sqrt{3}\pi\sqrt{\frac{6.37\times10^6\ \text{m}}{9.81\ \text{m/s}^2}}$$
$$= 2.631\times10^4\ \text{s}\times\frac{1\ \text{h}}{3600\ \text{s}} = \boxed{7.31\ \text{h}}$$

(b) Using its definition, express the spacecraft's kinetic energy:

$$K = \tfrac{1}{2}mv^2 = \tfrac{1}{2}m\left(\tfrac{1}{3}gR_E\right)$$

Substitute numerical values and evaluate K:

$$K = \tfrac{1}{6}(100\ \text{kg})(9.81\ \text{m/s}^2)(6.37\times10^6\ \text{m})$$
$$= \boxed{1.04\ \text{GJ}}$$

(c) Express the kinetic energy of the spacecraft in terms of its angular momentum:

$$K = \frac{L^2}{2I}$$

Solve for L:

$$L = \sqrt{2IK}$$

Express the moment of inertia of the spacecraft with respect to an axis through the center of the earth:

$$I = m(3R_E)^2$$
$$= 9mR_E^2$$

Substitute and solve for L:

$$L = \sqrt{18mR_E^2K} = 3R_E\sqrt{2mK}$$

Substitute numerical values and evaluate L:

$$L = 3(6.37\times10^6\ \text{m})\sqrt{2(100\ \text{kg})(1.04\times10^9\ \text{J})} = \boxed{8.72\times10^{12}\ \text{J}\cdot\text{s}}$$

***54** •

Picture the Problem Let the origin of our coordinate system be at the center of the earth and let the positive x direction be toward the moon. We can apply the definition of center of mass to find the center of mass of the earth-moon system and find the "orbital" speed of the earth using x_{cm} as the radius of its motion and the period of the moon as the period of this motion of the earth.

(a) Using its definition, express the x coordinate of the center of mass of the earth-moon system:

$$x_{cm} = \frac{M_E x_E + m_{moon}x_{moon}}{M_E + m_{moon}}$$

Substitute numerical values and evaluate x_{cm}:

$$x_{cm} = \frac{M_E(0) + (7.36\times10^{22}\text{ kg})(3.82\times10^{8}\text{ m})}{5.98\times10^{24}\text{ kg} + 7.36\times10^{22}\text{ kg}} = \boxed{4.64\times10^{6}\text{ m}}$$

Note that, because the radius of the earth is 6.37×10^6 m, the center of mass is actually located about 1700 km *below* the surface of the earth.

(*b*) Express the "orbital" speed of the earth in terms of the radius of its circular orbit and its period of rotation:

$$v = \frac{2\pi x_{cm}}{T}$$

Substitute numerical values and evaluate v:

$$v = \frac{2\pi(4.64\times10^{6}\text{ m})}{27.3\text{ d}\times\frac{24\text{ h}}{\text{d}}\times\frac{3600\text{ s}}{\text{h}}} = \boxed{12.4\text{ m/s}}$$

55 ••

Picture the Problem We can express the energy difference between these two orbits in terms of the total energy of a satellite at each elevation. The application of Newton's 2nd law to the force acting on a satellite will allow us to express the total energy of each satellite as function of its mass, the radius of the earth, and its orbital radius.

Express the energy difference:

$$\Delta E = E_{geo} - E_{1000} \quad (1)$$

Express the total energy of an orbiting satellite:

$$E_{tot} = K + U = \tfrac{1}{2}mv^2 - \frac{GM_E m}{R} \quad (2)$$

where R is the orbital radius.

Apply Newton's 2nd law to a satellite to relate the gravitational force to the orbital speed:

$$F_{radial} = \frac{GM_E m}{R^2} = m\frac{v^2}{R}$$

or

$$\frac{gR_E^2}{R^2} = \frac{v^2}{R}$$

Simplify and solve for v^2:

$$v^2 = \frac{gR_E^2}{R}$$

Substitute in equation (2) to obtain:

$$E_{tot} = \tfrac{1}{2}m\frac{gR_E^2}{R} - \frac{gR_E^2 m}{R} = -\frac{mgR_E^2}{2R}$$

Substitute in equation (1) and simplify to obtain:

$$\Delta E = -\frac{mgR_E^2}{2R_{geo}} + \frac{mgR_E^2}{2R_{1000}} = \frac{mgR_E^2}{2}\left(\frac{1}{R_{1000}} - \frac{1}{R_{geo}}\right)$$

Substitute numerical values and evaluate ΔE:

$$\Delta E = \tfrac{1}{2}(500\,\text{kg})(9.81\,\text{N/kg})(6.37\times10^6\,\text{m})^2\left(\frac{1}{7.37\times10^6\,\text{m}} - \frac{1}{4.22\times10^7\,\text{m}}\right) = \boxed{11.1\,\text{GJ}}$$

56 ••

Picture the Problem We can use Kepler's 3rd law to relate the periods of the moon and Earth, in their orbits about the earth and the sun, to their mean distances from the objects about which they are in orbit. We can solve these equations for the masses of the sun and the earth and then divide one by the other to establish a value for the ratio of the mass of the sun to the mass of the earth.

Using Kepler's 3rd law, relate the period of the moon to its mean distance from the earth:

$$T_m^2 = \frac{4\pi^2}{GM_E} r_m^3 \quad (1)$$

where r_m is the distance between the centers of the earth and the moon.

Using Kepler's 3rd law, relate the period of the earth to its mean distance from the sun:

$$T_E^2 = \frac{4\pi^2}{GM_s} r_E^3 \quad (2)$$

where r_E is the distance between the centers of the earth and the sun.

Solve equation (1) for M_E:

$$M_E = \frac{4\pi^2}{GT_m^2} r_m^3 \quad (3)$$

Solve equation (2) for M_s:

$$M_s = \frac{4\pi^2}{GT_E^2} r_E^3 \quad (4)$$

Divide equation (4) by equation (3) and simplify to obtain:

$$\frac{M_s}{M_E} = \left(\frac{r_E}{r_m}\right)^3\left(\frac{T_m}{T_E}\right)^2$$

Substitute numerical values and evaluate M_s/M_E:

$$\frac{M_s}{M_E} = \left(\frac{1.5\times10^{11}\,\text{m}}{3.82\times10^8\,\text{m}}\right)^3\left(\frac{27.3\,\text{d}}{365.24\,\text{d}}\right)^2 = \boxed{3.38\times10^5}$$

Express the difference between this value and the measured value of 3.33×10^5:

$$\%\,\text{diff} = \frac{3.38\times10^5 - 3.33\times10^5}{3.33\times10^5} = \boxed{1.50\,\%}$$

The Gravitational Field

57 •

Picture the Problem The gravitational field at any point is defined by $\vec{g} = \vec{F}/m$.

Using its definition, express the gravitational field at a point in space:

$$\vec{g} = \frac{\vec{F}}{m} = \frac{(12\,\text{N})\hat{i}}{3\,\text{kg}} = \boxed{(4\,\text{N/kg})\hat{i}}$$

***58** •

Picture the Problem The gravitational field at any point is defined by $\vec{g} = \vec{F}/m$.

Using its definition, express the gravitational field at a point in space:

$$\vec{g} = \frac{\vec{F}}{m}$$

Solve for $\vec{F}$ and substitute for m and $\vec{g}$ to obtain:

$$\vec{F} = m\vec{g} = (0.004\,\text{kg})(2.5\times10^{-6}\,\text{N/kg})\hat{j} = \boxed{(10^{-8}\,N)\hat{j}}$$

59 ••

Picture the Problem We can use the definition of the gravitational field due to a point mass to find the x and y components of the field at the origin and then add these components to find the resultant field. We can find the magnitude of the field from its components using the Pythagorean theorem.

(*a*) Express the gravitational field due to the point mass at $x = L$:

$$\vec{g}_x = \frac{Gm}{L^2}\hat{i}$$

Express the gravitational field due to the point mass at $y = L$:

$$\vec{g}_y = \frac{Gm}{L^2}\hat{j}$$

Add the two fields to obtain:

$$\vec{g} = \vec{g}_x + \vec{g}_y = \boxed{\frac{Gm}{L^2}\hat{i} + \frac{Gm}{L^2}\hat{j}}$$

(*b*) Find the magnitude of $\vec{g}$:

$$|\vec{g}| = \sqrt{g_x^2 + g_y^2} = \sqrt{\frac{Gm}{L^2} + \frac{Gm}{L^2}}$$
$$= \boxed{\sqrt{2}\frac{Gm}{L^2}}$$

60 ••

Picture the Problem We can find the net force acting on *m* by superposition of the forces due to each of the objects arrayed on the circular arc. Once we have expressed the net force, we can find the gravitational field at the center of curvature from its definition.

(*a*) Express the net force acting on *m*:

$$\vec{F} = F_x\hat{i} + F_y\hat{j} \quad (1)$$

Express F_x:

$$F_x = \frac{GMm}{R^2} - \frac{GMm}{R^2} + \frac{GMm}{R^2}\cos 45° - \frac{GMm}{R^2}\cos 45° = 0$$

Express F_y:

$$F_y = \frac{GMm}{R^2} + \frac{GMm}{R^2}\sin 45° + \frac{GMm}{R^2}\sin 45° = \frac{GMm}{R^2}(2\sin 45° + 1)$$

Substitute numerical values and evaluate F_y:

$$F_y = \frac{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)}{(0.1\ \text{m})^2}\times(3\ \text{kg})(2\ \text{kg})(2\sin 45° + 1) = 9.67\times10^{-8}\ \text{N}$$

Substitute in equation (1) to obtain:

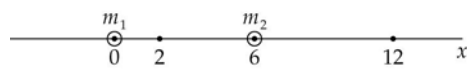
$$\vec{F} = \boxed{0\hat{i} + (9.67\times10^{-8}\ \text{N})\hat{j}}$$

(*b*) Using its definition, express $\vec{g}$ at the center of curvature of the arc:

$$\vec{g} = \frac{\vec{F}}{m} = \frac{0\hat{i} + (9.67\times10^{-8}\ \text{N})\hat{j}}{2\ \text{kg}}$$
$$= \boxed{(4.83\times10^{-8}\ \text{N/kg})\hat{j}}$$

61 ••

Picture the Problem The configuration of point masses is shown to the right. The gravitational field at any point can be found by superimposing the fields due to each of the point masses.



(*a*) Express the gravitational field at $x = 2$ m as the sum of the fields due to the point masses m_1 and m_2:

$$\vec{g} = \vec{g}_1 + \vec{g}_2 \qquad (1)$$

Express $\vec{g}_1$ and $\vec{g}_2$:

$$\vec{g}_1 = -\frac{Gm_1}{x_1^2}\hat{i} \text{ and } \vec{g}_2 = \frac{Gm_2}{x_2^2}\hat{i}$$

Substitute in equation (1) to obtain:

$$\vec{g} = -\frac{Gm_1}{x_1^2}\hat{i} + \frac{Gm_2}{x_2^2}\hat{i} = -\frac{Gm_1}{x_1^2}\hat{i} + \frac{Gm_2}{(2x_1)^2}\hat{i} = -\frac{G}{x_1^2}\left(m_1 - \tfrac{1}{4}m_2\right)\hat{i}$$

Substitute numerical values and evaluate $\vec{g}$:

$$\vec{g} = -\frac{6.6726\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2}{(2\,\text{m})^2} \times\left[2\,\text{kg} - \tfrac{1}{4}(4\,\text{kg})\right]\hat{i} = \boxed{\left(-1.67\times10^{-11}\,\text{N/kg}\right)\hat{i}}$$

(*b*) Express $\vec{g}_1$ and $\vec{g}_2$:

$$\vec{g}_1 = -\frac{Gm_1}{x_1^2}\hat{i} \text{ and } \vec{g}_2 = -\frac{Gm_2}{x_2^2}\hat{i}$$

Substitute in equation (1) to obtain:

$$\vec{g} = -\frac{Gm_1}{x_1^2}\hat{i} - \frac{Gm_2}{x_2^2}\hat{i} = -\frac{Gm_1}{(2x_2)^2}\hat{i} - \frac{Gm_2}{x_2^2}\hat{i} = -\frac{G}{x_2^2}\left(\tfrac{1}{4}m_1 + m_2\right)\hat{i}$$

Substitute numerical values and evaluate $\vec{g}$:

$$\vec{g} = -\frac{6.6726\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2}{(6\,\text{m})^2}\times\left[\tfrac{1}{4}(2\,\text{kg})+4\,\text{kg}\right]\hat{i} = \boxed{\left(-8.34\times10^{-12}\ \text{N/kg}\right)\hat{i}}$$

(*c*) Express the condition that $\vec{g} = 0$:

$$\frac{Gm_1}{x^2}-\frac{Gm_2}{(6-x)^2}=0$$

or

$$\frac{2}{x^2}-\frac{4}{(6-x)^2}=0$$

Express this quadratic equation in standard form:

$x^2+12x-36=0$, where x is in meters.

Solve the equation to obtain:

$x = 2.48\,\text{m}$ and $x = -14.5\,\text{m}$

From the diagram it is clear that the physically meaningful root is the positive one at:

$$x = \boxed{2.48\,\text{m}}$$

62 ••

Picture the Problem To show that the maximum value of $|g_x|$ for the field of Example 11-7 occurs at the points $x = \pm a/\sqrt{2}$, we can differentiate g_x with respect to x and set the derivative equal to zero.

From Example 11-7:

$$g_x = -\frac{2GMx}{\left(x^2+a^2\right)^{3/2}}$$

Differentiate g_x with respect to x and set the derivative equal to zero to find extreme values:

$$\frac{dg_x}{dx} = -2GM\left[\left(x^2+a^2\right)^{-3/2}-3x^2\left(x^2+a^2\right)^{-5/2}\right]=0 \text{ for extrema.}$$

Solve for x to obtain:

$$x = \boxed{\pm\frac{a}{\sqrt{2}}}$$

Remarks: To establish that this value for x corresponds to a relative maximum, we need to either evaluate the second derivative of g_x at $x = \pm a/\sqrt{2}$ or examine the graph of $|g_x|$ at $x = \pm a/\sqrt{2}$ for concavity downward.

63 ••

Picture the Problem We can find the mass of the rod by integrating dm over its length. The gravitational field at $x_0 > L$ can be found by integrating $d\vec{g}$ at x_0 over the length of the rod.

(*a*) Express the total mass of the stick:

$$M = \int_0^L \lambda\, dx = C\int_0^L x dx = \boxed{\tfrac{1}{2}CL^2}$$

(*b*) Express the gravitational field due to an element of the stick of mass dm:

$$d\vec{g} = -\frac{Gdm}{(x_0 - x)^2}\hat{i} = -\frac{G\lambda\, dx}{(x_0 - x)^2}\hat{i}$$
$$= -\frac{GCxdx}{(x_0 - x)^2}\hat{i}$$

Integrate this expression over the length of the stick to obtain:

$$\vec{g} = -GC\int_0^L \frac{xdx}{(x_0 - x)^2}\hat{i}$$
$$= \boxed{\frac{2GM}{L^2}\left[\ln\left(\frac{x_0}{x_0 - L}\right) - \left(\frac{L}{x_0 - L}\right)\right]\hat{i}}$$

64 •••

Picture the Problem Choose a mass element dm of the rod of thickness dx at a distance x from the origin. All such elements produce a gravitational field at a point P located a distance $x_0 > \frac{1}{2}L$ from the origin. We can calculate the total field by integrating the magnitude of the field produced by dm from $x = -L/2$ to $x = +L/2$.

(*a*) Express the gravitational field at P due to the element dm:

$$d\vec{g}_x = -\frac{Gdm}{r^2}\hat{i}$$

Relate dm to dx:

$$dm = \frac{M}{L}dx$$

Express the distance r between dm and point P in terms of x and x_0:

$$r = x_0 - x$$

Substitute these results to express $d\vec{g}_x$ in terms of x and x_0:

$$d\vec{g}_x = \boxed{\left\{-\frac{GM}{L(x_0 - x)^2}dx\right\}\hat{i}}$$

(*b*) Integrate to find the total field:

$$\vec{g}_x = -\frac{GM}{L}\int_{-L/2}^{L/2}\frac{dx}{(x_0 - x)^2}\hat{i} = \left\{-\frac{GM}{L}\left[\frac{1}{x_0 - x}\right]_{-L/2}^{L/2}\right\}\hat{i} = \boxed{-\frac{GM}{x_0^2 - \frac{1}{4}L^2}\hat{i}}$$

(*c*) Use the definition of $\vec{g}$ to express $\vec{F}$:

$$\vec{F} = m_0\vec{g} = \boxed{-\frac{GMm_0}{x_0^2 - \frac{1}{4}L^2}\hat{i}}$$

(*d*) Factor x_0^2 from the denominator of our expression for $\vec{g}_x$ to obtain:

$$\vec{g}_x = -\frac{GM}{x_0^2\left(1 - \frac{L^2}{4x_0^2}\right)}\hat{i}$$

For $x_0 >> L$ the second term in parentheses is very small and:

$$\vec{g}_x \approx \boxed{-\frac{GM}{x_0^2}\hat{i}}$$

which is the gravitational field of a point mass M located at the origin.

$\vec{g}$ due to Spherical Objects

65 •

Picture the Problem The gravitational field inside a spherical shell is zero and the field at the surface of and outside the shell is given by $g = GM/r^2$.

(*a*) Because 0.5 m < R:

$$g = \boxed{0}$$

(*b*) Because 1.9 m < R:

$$g = \boxed{0}$$

(*c*) Because 2.5 m > R:

$$g = \frac{GM}{r^2} = \frac{(6.6726\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2)(300\,\text{kg})}{(2.5\,\text{m})^2} = \boxed{3.20\times10^{-9}\,\text{N/kg}}$$

66 •

Determine the Concept The gravitational attraction is zero. The gravitational field inside the 2 m shell due to that shell is zero; therefore, it exerts no force on the 1 m shell, and, by Newton's 3rd law, that shell exerts no force on the larger shell.

***67 •**

Picture the Problem The gravitational field and acceleration of gravity at the surface of a sphere given by $g = GM/R^2$, where R is the radius of the sphere and M is its mass.

Express the acceleration of gravity on the surface of S_1:

$$g_1 = \frac{GM}{R^2}$$

Express the acceleration of gravity on the surface of S_2:

$$g_2 = \frac{GM}{R^2}$$

Divide the second of these equations by the first to obtain:

$$\frac{g_2}{g_1} = \frac{\frac{GM}{R^2}}{\frac{GM}{R^2}} = 1 \text{ or } \boxed{g_1 = g_2}$$

68 ••

Picture the Problem The gravitational field and acceleration of gravity at the surface of a sphere given by $g = GM/R^2$, where R is the radius of the sphere and M is its mass.

Express the acceleration of gravity on the surface of S_1:

$$g_1 = \frac{GM}{R_1^2}$$

Express the acceleration of gravity on the surface of S_2:

$$g_2 = \frac{GM}{R_2^2}$$

Divide the second of these equations by the first to obtain:

$$\frac{g_2}{g_1} = \frac{\frac{GM}{R_2^2}}{\frac{GM}{R_1^2}} = \frac{R_1^2}{R_2^2}$$

Solve for g_2:

$$g_2 = \boxed{\frac{R_1^2}{R_2^2} g_1}$$

Remarks: The accelerations depend only on the masses and radii because the points of interest are outside spherically symmetric distributions of mass.

69 ••

Picture the Problem The magnitude of the gravitational force is $F = mg$ where g inside a spherical shell is zero and outside is given by $g = GM/r^2$.

(*a*) At $r = 3a$, the masses of both spheres contribute to g:

$$F = mg = m\frac{G(M_1 + M_2)}{(3a)^2} = \boxed{\frac{Gm(M_1 + M_2)}{9a^2}}$$

(*b*) At $r = 1.9a$, g due to $M_2 = 0$:

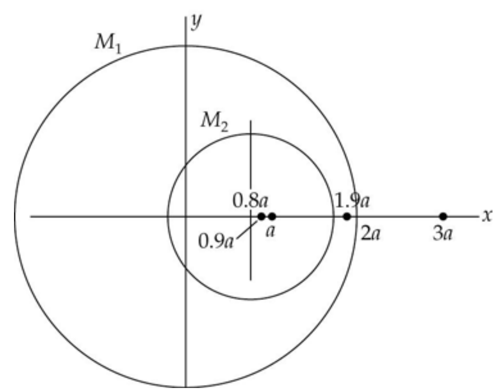
$$F = mg = m\frac{GM_1}{(1.9a)^2} = \boxed{\frac{GmM_1}{3.61a^2}}$$

(*c*) At $r = 0.9a$, $g = 0$:

$$F = \boxed{0}$$

70 ••

Picture the Problem The configuration is shown on the right. The centers of the spheres are indicated by the center-lines. The x coordinates of the mass m for parts (*a*), (*b*), and (*c*) are indicated along the x axis. The magnitude of the gravitational force is $F = mg$ where g inside a spherical shell is zero and outside is given by $g = \frac{GM}{r^2}$.



(*a*) Express the force acting on the object whose mass is m:

$$F = m(g_{1x} + g_{2x})$$

Find g_{1x} at $x = 3a$:

$$g_{1x} = \frac{GM_1}{(3a)^2} = \frac{GM_1}{9a^2}$$

Find g_{2x} at $x = 3a$:

$$g_{2x} = \frac{GM_2}{(3a - 0.8a)^2} = \frac{GM_2}{4.84a^2}$$

Substitute to obtain:

$$F = m\left(\frac{GM_1}{9a^2} + \frac{GM_2}{4.84a^2}\right) = \boxed{\frac{Gm}{a^2}\left(\frac{M_1}{9} + \frac{M_2}{4.84}\right)}$$

(*b*) Find g_{2x} at $x = 1.9a$:

$$g_{2x} = \frac{GM_2}{(1.9a - 0.8a)^2} = \frac{GM_2}{1.21a^2}$$

Find g_{1x} at $x = 1.9a$:

$$g_{1x} = 0$$

Substitute to obtain:

$$F = mg = \boxed{\frac{GmM_2}{1.21a^2}}$$

(*c*) At $x = 0.9a$, $g_{1x} = g_{2x} = 0$:

$$F = \boxed{0}$$

$\vec{g}$ Inside Solid Spheres

***71 ••**

Picture the Problem The "weight" as measured by a spring scale will be the normal force which the spring scale presses up against you. There are two forces acting on you as you stand at a distance r from the center of the planet: the normal force (F_N) and the force of gravity (mg). Because you are in equilibrium under the influence of these forces, your weight (the scale reading or normal force) will be equal to the gravitational force acting on you. We can use Newton's law of gravity to express this force.

(*a*) Express the force of gravity acting on you when you are a distance r from the center of the earth:

$$F_g = \frac{GM(r)m}{r^2} \qquad (1)$$

Using the definition of density, express the density of the earth between you and the center of the earth and the density of the earth as a whole:

$$\rho = \frac{M(r)}{V(r)} = \frac{M(r)}{\frac{4}{3}\pi r^3}$$

and

$$\rho = \frac{M_E}{V_E} = \frac{M_E}{\frac{4}{3}\pi R^3}$$

Because we're assuming the earth to of uniform-density and perfectly spherical:

$$\frac{M(r)}{\frac{4}{3}\pi r^3} = \frac{M_E}{\frac{4}{3}\pi R^3}$$

or

$$M(r) = M_E\left(\frac{r}{R}\right)^3$$

Substitute in equation (1) and simplify to obtain:

$$F_g = \frac{GM_E\left(\frac{r}{R}\right)^3 m}{r^2} = \frac{GM_E m}{R^2}\frac{r}{R}$$

Apply Newton's law of gravity to yourself at the surface of the earth to obtain:

$$mg = \frac{GM_{\text{E}}m}{R^2}$$

or

$$g = \frac{GM_{\text{E}}}{R^2}$$

where g is the magnitude of free-fall acceleration at the surface of the earth.

Substitute to obtain:

$$F_g = \boxed{\frac{mg}{R}r}$$

i.e., the force of gravity on you is proportional to your distance from the center of the earth.

(*b*) Apply Newton's 2nd law to your body to obtain:

$$F_{\text{N}} - mg\frac{r}{R} = -mr\omega^2$$

Solve for your "effective weight" (i.e., what a spring scale will measure) F_{N}:

$$F_{\text{N}} = \frac{mg}{R}r - mr\omega^2 = \boxed{\left(\frac{mg}{R} - m\omega^2\right)r}$$

Note that this equation tells us that your effective weight increases linearly with distance from the center of the earth. The second term can be interpreted as a "centrifugal force" pushing out, which increases the farther you get from the center of the earth.

(*c*) We can decide whether the change in mass with distance from the center of the earth or the rotational effect is more important by examining the ratio of the two terms in the expression for your effective weight:

$$\frac{\frac{mg}{R}r}{mr\omega^2} = \frac{\frac{g}{R}}{\omega^2} = \frac{g}{R\left(\frac{2\pi}{T}\right)^2} = \frac{gT^2}{4\pi^2 R}$$

Substitute numerical values and evaluate this ratio:

$$\frac{gT^2}{4\pi^2 R} = \frac{\left(9.81\,\text{m/s}^2\right)\left(24\,\text{h} \times \frac{3600\,\text{s}}{\text{h}}\right)^2}{4\pi^2\left(6370\,\text{km}\right)} = 291$$

The change in the mass between you and the center of the earth as you move away from the center is 291 times more important than the rotational effect.

72 ••

Picture the Problem We can find the loss in weight at this depth by taking the difference between the weight of the student at the surface of the earth and her weight at a depth d = 15 km. To find the gravitational field at depth d, we'll use its definition and the mass of the earth that is between the bottom of the shaft and the center of the earth. We'll assume (incorrectly) that the density of the earth is constant.

Express the loss in weight:

$$\Delta w = w(R_E) - w(R) \quad (1)$$

Express the mass M inside $R = R_E - d$:

$$M = \rho V = \tfrac{4}{3}\rho\pi(R_E - d)^3$$

Express the mass of the earth:

$$M_E = \rho V_E = \tfrac{4}{3}\rho\pi R_E^3$$

Divide the first of these equations by the second to obtain:

$$\frac{M}{M_E} = \frac{\tfrac{4}{3}\rho\pi(R_E - d)^3}{\tfrac{4}{3}\rho\pi R_E^3} = \frac{(R_E - d)^3}{R_E^3}$$

Solve for M:

$$M = M_E \frac{(R_E - d)^3}{R_E^3}$$

Express the gravitational field at $R = R_E - d$:

$$g = \frac{GM}{R^2} = \frac{GM_E(R_E - d)^3}{(R_E - d)^2 R_E^2} \quad (2)$$

Express the gravitational field at $R = R_E$:

$$g_E = \frac{GM_E}{R_E^2} \quad (3)$$

Divide equation (2) by equation (3) to obtain:

$$\frac{g}{g_E} = \frac{\dfrac{GM_E(R_E - d)^3}{(R_E - d)^2 R_E^2}}{\dfrac{GM_E}{R_E^2}} = \frac{R_E - d}{R_E}$$

Solve for g:

$$g = \frac{R_E - d}{R_E} g_E$$

Express the weight of the student at $R = R_E - d$:

$$w(R) = mg(R) = \frac{R_E - d}{R_E} mg_E = \left(1 - \frac{d}{R_E}\right) mg_E$$

Substitute in equation (1) to obtain:

$$\Delta w = mg_{\text{E}} - \left(1 - \frac{d}{\text{R}_{\text{E}}}\right)mg_{\text{E}} = \frac{mg_{\text{E}}d}{R_{\text{E}}}$$

Substitute numerical values and evaluate Δw:

$$\Delta w = \frac{(800\,\text{N})(15\,\text{km})}{6370\,\text{km}} = \boxed{1.88\,\text{N}}$$

73 ••

Picture the Problem We can use the hint to find the gravitational field along the x axis.

Using the hint, express $g(x)$:

$$g(x) = g_{\text{solid sphere}} + g_{\text{hollow sphere}}$$

Substitute for $g_{\text{solid sphere}}$ and $g_{\text{hollow sphere}}$ and simplify to obtain:

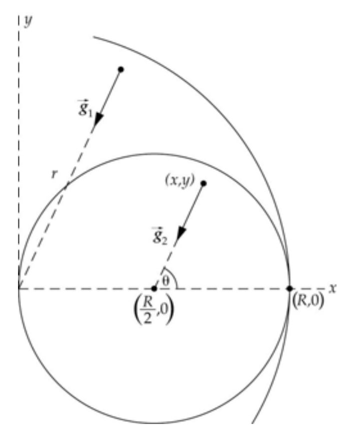
$$g(x) = \frac{GM_{\text{solid sphere}}}{x^2} + \frac{GM_{\text{hollow sphere}}}{\left(x - \frac{1}{2}R\right)^2}$$

$$= \frac{G\rho_0\left(\frac{4}{3}\pi R^3\right)}{x^2} + \frac{G\rho_0\left[-\frac{4}{3}\pi\left(\frac{1}{2}R\right)^3\right]}{\left(x - \frac{1}{2}R\right)^2}$$

$$= \boxed{G\left(\frac{4\pi\rho_0 R^3}{3}\right)\left[\frac{1}{x^2} - \frac{1}{8\left(x - \frac{1}{2}R\right)^2}\right]}$$

74 •••

Picture the Problem The diagram shows the portion of the solid sphere in which the hollow sphere is embedded. $\vec{g}_1$ is the field due to the solid sphere of radius R and density ρ_0 and $\vec{g}_2$ is the field due to the sphere of radius ½R and negative density ρ_0 centered at ½R. We can find the resultant field by adding the x and y components of $\vec{g}_1$ and $\vec{g}_2$.



Use its definition to express $|\vec{g}_1|$:

$$|\vec{g}_1| = \frac{GM}{r^2} = \frac{G\rho_0 V}{r^2} = \frac{4\pi\rho_0 r^3 G}{3r^2}$$

$$= \frac{4\pi\rho_0 rG}{3}$$

Find the x and y components of $\vec{g}_1$:

$$g_{1x} = -g_1\cos\theta = -g_1\left(\frac{x}{r}\right) = -\frac{4\pi\rho_0 Gx}{3}$$

and

$$g_{1y} = -g_1 \sin\theta = -g_1\left(\frac{y}{r}\right) = -\frac{4\pi\rho_0 G y}{3}$$

where the negative signs indicate that the field points inward.

Use its definition to express $|\vec{g}_2|$:

$$|\vec{g}_2| = \frac{GM_2}{r^2} = \frac{G\rho_0 V_2}{r_2^2} = \frac{4\pi\rho_0 r_2^3 G}{3r_2^2}$$
$$= \frac{4\pi\rho_0 r_2 G}{3}$$

where $r_2 = \sqrt{\left(x - \frac{1}{2}R\right)^2 + y^2}$

Express the x and y components of $\vec{g}_2$:

$$g_{2x} = g_2\left(\frac{x - \frac{1}{2}R}{r_2}\right) = \frac{4\pi\rho_0 G\left(x - \frac{1}{2}R\right)}{3}$$

$$g_{2y} = g_2\left(\frac{y}{r_2}\right) = \frac{4\pi\rho_0 G y}{3}$$

Add the x components to obtain the x component of the resultant field:

$$g_x = g_{1x} + g_{2x}$$
$$= -\frac{4\pi\rho_0 G x}{3} + \frac{4\pi\rho_0 G\left(x - \frac{1}{2}R\right)}{3}$$
$$= -\frac{2\pi\rho_0 G R}{3}$$

where the negative sign indicates that the field points inward.

Add the y components to obtain the y component of the resultant field:

$$g_y = g_{1y} + g_{2y}$$
$$= -\frac{4\pi\rho_0 G y}{3} + \frac{4\pi\rho_0 G y}{3} = 0$$

Express $\vec{g}$ in vector form and evaluate $|\vec{g}|$:

$$\vec{g} = g_x\hat{i} + G_y\hat{j} = \boxed{\left(-\frac{2\pi\rho_0 G R}{3}\right)\hat{i}}$$

and

$$|\vec{g}| = \boxed{\frac{2\pi\rho_0 G R}{3}}$$

75 •••

Picture the Problem The gravitational field will exert an inward radial force on the objects in the tunnel. We can relate this force to the angular velocity of the planet by using Newton's 2nd law of motion.

Letting r be the distance from the objects to the center of the planet, use Newton's 2nd law to relate the gravitational force acting on the objects to their angular velocity:

$$F_{net} = F_g = mr\omega^2$$

or

$$mg = mr\omega^2$$

Solve for ω to obtain:

$$\omega = \sqrt{\frac{g}{r}} \quad (1)$$

Use its definition to express g:

$$g = \frac{GM}{r^2} = \frac{G\rho_0 V}{r^2} = \frac{4\pi\rho_0 r^3 G}{3r^2} = \frac{4\pi\rho_0 rG}{3}$$

Substitute in equation (1) and simplify:

$$\omega = \sqrt{\frac{\frac{4\pi\rho_0 rG}{3}}{r}} = \boxed{\sqrt{\frac{4\pi\rho_0 G}{3}}}$$

76 •••

Picture the Problem Because we're given the mass of the sphere, we can find C by expressing the mass of the sphere in terms of C. We can use its definition to find the gravitational field of the sphere both inside and outside its surface.

(a) Express the mass of a differential element of the sphere:

$$dm = \rho\, dV = \rho\left(4\pi\, r^2 dr\right)$$

Integrate to express the mass of the sphere in terms of C:

$$M = 4\pi\, C \int_0^{5\,\text{m}} r dr = \left(50\,\text{m}^2\right)\pi\, C$$

Solve for C:

$$C = \frac{M}{\left(50\,\text{m}^2\right)\pi}$$

Substitute numerical values and evaluate C:

$$C = \frac{1011\,\text{kg}}{\left(50\,\text{m}^2\right)\pi} = \boxed{6.436\,\text{kg/m}^2}$$

(b) Use its definition to express the gravitational field of the sphere at a distance from its center greater than its radius:

$$g = \frac{GM}{r^2}$$

(1) For $r > 5$ m:

$$g = \frac{\left(6.6726\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)(1011\,\text{kg})}{r^2} = \boxed{\frac{6.75\times10^{-8}\ \text{N/kg}}{r^2}}$$

Use its definition to express the gravitational field of the sphere at a distance from its center less than its radius:

$$g = G\frac{\int_0^r 4\pi r^2\rho\,dr}{r^2} = G\frac{\int_0^r 4\pi r^2\frac{C}{r}\,dr}{r^2}$$

$$= G\frac{4\pi C\int_0^r r\,dr}{r^2} = 2\pi GC$$

(2) For $r < 5$ m:

$$g = 2\pi\left(6.6726\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)\times\left(6.436\,\text{kg/m}^2\right) = \boxed{2.70\times10^{-9}\ \text{N/kg}}$$

Remarks: Note that *g* is continuous at *r* = 5 m.

***77** •••

Picture the Problem We can use conservation of energy to relate the work done by the gravitational field to the speed of the small object as it strikes the bottom of the hole. Because we're given the mass of the sphere, we can find *C* by expressing the mass of the sphere in terms of *C*. We can then use its definition to find the gravitational field of the sphere inside its surface. The work done by the field equals the negative of the change in the potential energy of the system as the small object falls in the hole.

Use conservation of energy to relate the work done by the gravitational field to the speed of the small object as it strikes the bottom of the hole:

$$K_f - K_i + \Delta U = 0$$

or, because $K_i = 0$ and $W = -\Delta U$,

$$W = \tfrac{1}{2}mv^2$$

where *v* is the speed with which the object strikes the bottom of the hole and *W* is the work done by the gravitational field.

Solve for *v*:

$$v = \sqrt{\frac{2W}{m}} \qquad (1)$$

Express the mass of a differential element of the sphere:

$$dm = \rho\,dV = \rho\left(4\pi r^2 dr\right)$$

Integrate to express the mass of the sphere in terms of C:

$$M = 4\pi C \int_0^{5\,\text{m}} r dr = \left(50\,\text{m}^2\right)\pi C$$

Solve for and evaluate C:

$$C = \frac{M}{\left(50\,\text{m}^2\right)\pi} = \frac{1011\,\text{kg}}{\left(50\,\text{m}^2\right)\pi} = 6.436\,\text{kg/m}^2$$

Use its definition to express the gravitational field of the sphere at a distance from its center less than its radius:

$$g = G\frac{\int_0^r 4\pi r^2 \rho\, dr}{r^2} = G\frac{\int_0^r 4\pi r^2 \frac{C}{r} dr}{r^2} = G\frac{4\pi C\int_0^r r\, dr}{r^2} = 2\pi GC$$

Express the work done on the small object by the gravitational force acting on it:

$$W = -\int_{5\,\text{m}}^{3\,\text{m}} mgdr = (2\,\text{m})mg$$

Substitute in equation (1) and simplify to obtain:

$$v = \sqrt{\frac{2(2\,\text{m})m(2\pi GC)}{m}} = \sqrt{(8\,\text{m})\pi GC}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{(8\,\text{m})\pi\left(6.6726\times 10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(6.436\,\text{kg/m}^2\right)} = \boxed{0.104\,\text{mm/s}}$$

78 •••

Picture the Problem The spherical deposit of heavy metals will increase the gravitational field at the surface of the earth. We can express this increase in terms of the difference in densities of the deposit and the earth and then form the quotient $\Delta g/g$.

Express Δg due to the spherical deposit:

$$\Delta g = \frac{G\Delta M}{r^2} \qquad (1)$$

Express the mass of the spherical deposit:

$$M = \Delta\rho V = \Delta\rho\left(\tfrac{4}{3}\pi R^3\right) = \tfrac{4}{3}\pi\Delta\rho R^3$$

Substitute in equation (1):

$$\Delta g = \frac{\tfrac{4}{3}G\pi\Delta\rho R^3}{r^2}$$

Express $\Delta g/g$:

$$\frac{\Delta g}{g}=\frac{\frac{\frac{4}{3}G\pi\,\Delta\rho\,R^3}{r^2}}{g}=\frac{\frac{4}{3}G\pi\,\Delta\rho\,R^3}{gr^2}$$

Substitute numerical values and evaluate $\Delta g/g$:

$$\frac{\Delta g}{g}=\frac{\frac{4}{3}\pi\left(6.6726\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(5000\,\text{kg/m}^3\right)\left(1000\,\text{m}\right)^3}{\left(9.81\,\text{N/kg}\right)\left(2000\,\text{m}\right)^2}=\boxed{3.56\times10^{-5}}$$

***79 •••**

Picture the Problem The force of attraction of the small sphere of mass m to the lead sphere is the sum of the forces due to the solid sphere ($\vec{F}_S$) and the cavities ($\vec{F}_C$) of negative mass.

(*a*) Express the force of attraction:

$$\vec{F}=\vec{F}_S+\vec{F}_C \qquad (1)$$

Use the law of gravity to express the force due to the solid sphere:

$$\vec{F}_S=-\frac{GMm}{d^2}\hat{i}$$

Express the magnitude of the force acting on the small sphere due to one cavity:

$$F_C=\frac{GM'm}{d^2+\left(\frac{R}{2}\right)^2}$$

where M' is the negative mass of a cavity.

Relate the negative mass of a cavity to the mass of the sphere before hollowing:

$$M'=-\rho V=-\rho\left[\tfrac{4}{3}\pi\left(\frac{R}{2}\right)^3\right]$$
$$=-\tfrac{1}{8}\left(\tfrac{4}{3}\pi\rho R^3\right)=-\tfrac{1}{8}M$$

Letting θ be the angle between the x axis and the line joining the center of the small sphere to the center of either cavity, use the law of gravity to express the force due to the two cavities:

$$\vec{F}_C=2\frac{GMm}{8\left(d^2+\frac{R^2}{4}\right)}\cos\theta\,\hat{i}$$

because, by symmetry, the y components add to zero.

Express $\cos\theta$:

$$\cos\theta=\frac{d}{\sqrt{d^2+\frac{R^2}{4}}}$$

Substitute to obtain:

$$\vec{F}_C = \frac{GMm}{4\left(d^2+\frac{R^2}{4}\right)}\frac{d}{\sqrt{d^2+\frac{R^2}{4}}}\hat{i} = \frac{GMmd}{4\left(d^2+\frac{R^2}{4}\right)^{3/2}}\hat{i}$$

Substitute in equation (1) and simplify:

$$\vec{F} = -\frac{GMm}{d^2}\hat{i} + \frac{GMmd}{4\left(d^2+\frac{R^2}{4}\right)^{3/2}}\hat{i}$$

$$= \boxed{-\frac{GMm}{d^2}\left[1-\frac{\frac{d^3}{4}}{\left\{d^2+\frac{R^2}{4}\right\}^{3/2}}\right]\hat{i}}$$

(*b*) Evaluate $\vec{F}$ at $d = R$:

$$\vec{F}(R) = -\frac{GMm}{R^2}\left[1-\frac{\frac{R^3}{4}}{\left\{R^2+\frac{R^2}{4}\right\}^{3/2}}\right]\hat{i}$$

$$= \boxed{-0.821\frac{GMm}{R^2}\hat{i}}$$

80 ••

Picture the Problem Let *R* be the size of the cluster, and *N* the total number of stars in it. We can apply Newton's law of gravity and the 2nd law of motion to relate the net force (which depends on the number of stars *N*(*r*) in a sphere whose radius is equal to the distance between the star of interest and the center of the cluster) acting on a star at a distance *r* from the center of the cluster to its speed. We can use the definition of density, in conjunction with the assumption of uniform distribution of the starts within the cluster, to find *N*(*r*) and, ultimately, express the orbital speed *v* of a star in terms of the total mass of the cluster.

Using Newton's law of gravity and 2nd law, express the force acting on a star at a distance *r* from the center of the cluster:

$$F(r) = \frac{GN(r)M^2}{r^2} = M\frac{v^2}{r}$$

where *N*(*r*) is the number of stars within a distance *r* of the center of the cluster and *M* is the mass of an individual star.

Using the uniform distribution assumption and the definition of density, relate the number of stars $N(r)$ within a distance r of the center of the cluster to the total number N of stars in the cluster:

$$\rho = \frac{N(r)M}{\frac{4}{3}\pi r^3} = \frac{NM}{\frac{4}{3}\pi R^3}$$

or

$$N(r) = N\frac{r^3}{R^3}$$

Substitute to obtain:

$$\frac{GNM^2}{r^2}\frac{r^3}{R^3} = M\frac{v^2}{r}$$

or

$$GNM\frac{r^2}{R^3} = v^2$$

Solve for v to obtain:

$$v = r\sqrt{\frac{GNM}{R^3}} \Rightarrow v \propto r$$

The mean velocity v of a star in a circular orbit around the center of the cluster increases linearly with distance r from the center.

General Problems

***81 •**

Picture the Problem We can use Kepler's 3rd law to relate Pluto's period to its mean distance from the sun.

Using Kepler's 3rd law, relate the period of Pluto to its mean distance from the sun:

$$T^2 = Cr^3$$

where $C = \frac{4\pi^2}{GM_s} = 2.973\times10^{-19}\ \text{s}^2/\text{m}^3$.

Solve for T:

$$T = \sqrt{Cr^3}$$

Substitute numerical values and evaluate T:

$$T = \sqrt{\left(2.973\times10^{-19}\ \text{s}^2/\text{m}^3\right)\left(39.5\ \text{AU}\times\frac{1.50\times10^{11}\ \text{m}}{\text{AU}}\right)^3}$$

$$= 7.864\times10^9\ \text{s}\times\frac{1\ \text{h}}{3600\ \text{s}}\times\frac{1\ \text{d}}{24\ \text{h}}\times\frac{1\ \text{y}}{365.25\ \text{d}}$$

$$= \boxed{249\ \text{y}}$$

82 •

Picture the Problem Consider an object of mass m at the surface of the earth. We can relate the weight of this object to the gravitational field of the earth and to the mass of the earth.

Using Newton's 2nd law, relate the weight of an object at the surface of the earth to the gravitational force acting on it:

$$w = mg = \frac{GM_E m}{R_E^2}$$

Solve for M_E:

$$M_E = \frac{gR_E^2}{G}$$

Substitute numerical values and evaluate M_E:

$$M_E = \frac{(9.81\,\text{N/kg})(6.37\times10^6\,\text{m})^2}{6.6726\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2} = \boxed{5.97\times10^{24}\,\text{kg}}$$

83 ••

Picture the Problem The work you must do against gravity to move the particle from a distance r_1 to r_2 is the negative of the change in the particle's gravitational potential energy.

(*a*) Relate the work you must do to the change in the gravitational potential energy of the earth-particle system:

$$W = -\Delta U = -\int_{r_1}^{r_2} F_g dr = GM_E m\int_{r_1}^{r_2}\frac{dr}{r^2}$$

$$= -GM_E m\left(\frac{1}{r_2}-\frac{1}{r_1}\right)$$

$$= \boxed{GM_E m\left(\frac{1}{r_1}-\frac{1}{r_2}\right)}$$

(*b*) Substitute gR_E^2 for GM_E, R_E for r_1, and $R_E + h$ for r_2 to obtain:

$$W = \boxed{mgR_E^2\left(\frac{1}{R_E}-\frac{1}{R_E+h}\right)} \quad (1)$$

(*c*) Rewrite equation (1) with a common denominator and simplify to obtain:

$$W = mgR_E^2\left(\frac{R_E + h - R_E}{R_E(R_E + h)}\right)$$

$$= mgh\left(\frac{R_E}{R_E + h}\right) = mgh\left(\frac{1}{1+\frac{h}{R_E}}\right)$$

$$\approx \boxed{mgh}$$

when $h << R_E$.

84 ••

Picture the Problem The gravitational field outside a uniform sphere is given by $g = -GM/r^2$ and the field inside the sphere by $g = -(GM/R^3)r$.

(*a*) Express *g* outside the sphere:

$$g = -\frac{GM}{r^2}$$

Find the mass of the sphere:

$$M = \rho V = \rho\left(\tfrac{4}{3}\pi R^3\right)$$

Substitute and simplify to obtain:

$$g = -\frac{G\rho\left(\tfrac{4}{3}\pi R^3\right)}{r^2} = -\tfrac{4}{3}\frac{G\rho R^3}{r^2}$$

Substitute numerical values and evaluate *g*:

$$g = -\tfrac{4}{3}\frac{\left(6.673\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(2000\,\text{kg/m}^3\right)(100\,\text{m})^3}{r^2} = \boxed{-\frac{0.559\,\text{N}\cdot\text{m}^2/\text{kg}}{r^2}}$$

(*b*) Express the gravitational field inside the uniform sphere:

$$g = -\frac{GM}{R^3}r = -\frac{G\rho\left(\tfrac{4}{3}\pi R^3\right)}{R^3}r$$

$$= -\tfrac{4}{3}\pi\rho Gr$$

Substitute numerical values and evaluate *g*:

$$g = -\tfrac{4}{3}\pi\left(2000\,\text{kg/m}^3\right)\left(6.6726\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2\right)r = \boxed{-\left(5.59\times10^{-7}\,\text{N/kg}\cdot\text{m}\right)r}$$

85 ••

Picture the Problem We can use Kepler's 3rd law to relate the period of the satellite to its mean distance from the center of Jupiter.

Use Kepler's 3rd law to relate the period of the satellite to its mean distance from the center of Jupiter:

$$T^2 = \frac{4\pi^2}{GM_J}(R_J + h)^3$$

Solve for h:

$$h = \sqrt[3]{\frac{T^2 GM_J}{4\pi^2}} - R_J \qquad (1)$$

Express the mass of Jupiter in terms of the mass of the earth:

$$M_J = 320M_E$$

Express the volume of Jupiter in terms of the mass of the earth:

$$V_J = 1320V_E$$

Express the volumes of Jupiter and Earth in terms of their radii and solve for R_J:

$$R_J = \sqrt[3]{1320}R_E$$

Substitute in equation (1) to obtain:

$$h = \sqrt[3]{\frac{T^2 G\{320M_E\}}{4\pi^2}} - \sqrt[3]{1320}R_E$$

Express the period of the satellite in seconds:

$$\begin{aligned} T &= 9\,\text{h} + 50\,\text{min} \\ &= 9\,\text{h} \times \frac{3600\,\text{s}}{\text{h}} + 50\,\text{min} \times \frac{60\,\text{s}}{\text{min}} \\ &= 3.54 \times 10^4\,\text{s} \end{aligned}$$

Substitute numerical values and evaluate h:

$$\begin{aligned} h &= \sqrt[3]{\frac{(3.54\times10^4\,\text{s})^2(6.6726\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2)\{320(5.98\times10^{24}\,\text{kg})\}}{4\pi^2}} \\ &\quad - \sqrt[3]{1320}(6.37\times10^6\,\text{m}) \\ &= \boxed{8.96\times10^7\,\text{m}} \end{aligned}$$

86 ••

Picture the Problem Let m represent the mass of the spacecraft. From Kepler's 3rd law we know that its period will be a minimum when it is in orbit just above the surface of the moon. We'll use Newton's 2nd law to relate the angular velocity of the spacecraft to the gravitational force acting on it.

Relate the period of the spacecraft to its angular velocity:

$$T = \frac{2\pi}{\omega} \qquad (1)$$

Using Newton's 2nd law of motion, relate the gravitational force acting on the spacecraft when it is in orbit at the surface of the moon to the angular velocity of the spacecraft:

$$\sum F_{\text{radial}} = \frac{GM_{\text{M}}m}{R_{\text{M}}^2} = mR_{\text{M}}\omega^2$$

Solve for ω:

$$\omega = \sqrt{\frac{GM_{\text{M}}}{R_{\text{M}}^3}} = \sqrt{\frac{G\left(\frac{4}{3}\pi\rho R_{\text{M}}^3\right)}{R_{\text{M}}^3}} = \sqrt{\tfrac{4}{3}G\pi\rho}$$

Substitute in equation (1) and simplify to obtain:

$$T_{\text{min}} = \frac{2\pi}{\sqrt{\frac{4}{3}G\pi\rho}} = \sqrt{\frac{3\pi}{\rho G}}$$

Substitute numerical values and evaluate T_{min}:

$$T_{\text{min}} = \sqrt{\frac{3\pi}{\left(6.6726\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(3340\ \text{kg/m}^3\right)}} = 6503\ \text{s} = \boxed{1\ \text{h}\ 48\ \text{min}}$$

87 ••

Picture the Problem We can use conservation of energy to establish a relationship between the height h to which the projectile will rise and its initial speed. The application of Newton's 2nd law will relate the orbital speed, which is equal to the initial speed of the projectile, to the mass and radius of the moon.

Use conservation of energy to relate the initial energies of the projectile to its final energy:

$$K_{\text{f}} - K_{\text{i}} + U_{\text{f}} - U_{\text{i}} = 0$$

or, because $K_{\text{f}} = 0$,

$$-\tfrac{1}{2}mv^2 - \frac{GM_{\text{M}}m}{R_{\text{M}} + h} + \frac{GM_{\text{M}}m}{R_{\text{M}}} = 0$$

Solve for h:

$$h = R\left(\frac{1}{1 - \dfrac{v^2 R_{\text{M}}}{2GM_{\text{M}}}} - 1\right) \qquad (1)$$

Use Newton's 2nd law to relate velocity of the satellite to the

$$\sum F_{\text{radial}} = \frac{GM_{\text{M}}m}{R_{\text{M}}^2} = m\frac{v^2}{R_{\text{M}}}$$

gravitational force acting on it:

Solve for v^2:

$$v^2 = \frac{GM_M}{R_M}$$

Substitute for v^2 in equation (1) and simplify to obtain:

$$h = R\left(\frac{1}{1-\frac{1}{2}} - 1\right) = R = \boxed{1.70\,\text{Mm}}$$

***88** ••

Picture the Problem If we assume the astronauts experience a constant acceleration in the barrel of the cannon, we can use a constant-acceleration equation to relate their exit speed (the escape speed from the earth) to the acceleration they would need to undergo in order to reach that speed. We can use conservation of energy to express their escape speed in terms of the mass and radius of the earth and then substitute in the constant-acceleration equation to find their acceleration. To find the balance point between the earth and the moon we can equate the gravitational forces exerted by the earth and the moon at that point.

(*a*) Assuming constant acceleration down the cannon barrel, relate the ship's speed as it exits the barrel to the length of the barrel and the acceleration required to get the ship to escape speed:

$$v_e^2 = 2a\Delta\ell$$

where ℓ is the length of the cannon.

Solve for the acceleration:

$$a = \frac{v_e^2}{2\Delta\ell} \qquad (1)$$

Use conservation of energy to relate the initial energy of astronaut's ship to its energy when it has escaped the earth's gravitational field:

$$\Delta K + \Delta U = 0$$

or

$$K_f - K_i + U_f - U_i = 0$$

When the ship has escaped the earth's gravitational field:

$$K_f = U_f = 0$$

and

$$-K_i - U_i = 0$$

or

$$-\tfrac{1}{2}mv_e^2 - \left(-\frac{GM_E m}{R}\right) = 0$$

where m is the mass of the spaceship.

Solve for v_e^2 to obtain:

$$v_e^2 = \frac{2GM_E}{R}$$

Substitute in equation (1) to obtain:

$$a = \frac{GM_E}{\Delta \ell R}$$

Substitute numerical values and evaluate a:

$$a = \left(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)\times\frac{\left(5.98\times10^{24}\ \text{kg}\right)}{(274\ \text{m})(6370\ \text{km})}$$
$$= 2.29\times10^{5}\ \text{m/s}^2$$
$$\approx 23{,}300g$$
$$\boxed{\text{Survival is extremely unlikely!}}$$

(*b*) Let the distance from the center of the earth to the center of the moon be R, and the distance from the center of the spaceship to the earth be x. If M is the mass of the earth and m the mass of the moon, the forces will balance out when:

$$\frac{GM}{x^2} = \frac{Gm}{(R-x)^2}$$
or
$$\frac{x}{\sqrt{M}} = \frac{R-x}{\sqrt{m}}$$
where we've ignored the negative solution, as it doesn't indicate a point between the two bodies.

Solve for x to obtain:

$$x = \frac{R}{1+\sqrt{\dfrac{m}{M}}}$$

Substitute numerical values and evaluate x:

$$x = \frac{3.84\times10^{8}\ \text{m}}{1+\sqrt{\dfrac{7.36\times10^{22}\ \text{kg}}{5.98\times10^{24}\ \text{kg}}}} = \boxed{3.46\times10^{8}\ \text{m}}$$

(*c*) No it is not. During the entire trip, the astronauts would be in free-fall, and so would not seem to weigh anything.

89 ••

Picture the Problem Let the origin of our coordinate system be at the center of mass of the binary star system and let the distances of the stars from their center of mass be r_1 and r_2. The period of rotation is related to the angular velocity of the star system and we can use Newton's 2nd law of motion to relate this velocity to the separation of the stars.

Relate the square of the period of the motion of the stars to their angular velocity:

$$T^2 = \frac{4\pi^2}{\omega^2} \qquad (1)$$

Using Newton's 2nd law of motion, relate the gravitational force acting on the star whose mass is m_2 to the angular velocity of the system:

$$\sum F_{\text{radial}} = \frac{Gm_1m_2}{(r_1+r_2)^2} = m_2r_2\omega^2$$

Solve for ω^2:

$$\omega^2 = \frac{Gm_1}{r_2(r_1+r_2)^2} \qquad (2)$$

From the definition of the center of mass we have:

$$m_1r_1 = m_2r_2 \qquad (3)$$

where $r = r_1 + r_2 \qquad (4)$

Eliminate r_1 from equations (3) and (4) and solve for r_2:

$$r_2 = \frac{rm_1}{m_1+m_2}$$

Eliminate r_2 from equations (3) and (4) and solve for r_1:

$$r_1 = \frac{rm_2}{m_1+m_2}$$

Substitute for r_1 and r_2 in equation (2) to obtain:

$$\omega^2 = \frac{G(m_1+m_2)}{r^3}$$

Finally, substitute in equation (1) and simplify:

$$T^2 = \frac{4\pi^2}{\frac{G(m_1+m_2)}{r^3}} = \boxed{\frac{4\pi^2r^3}{G(m_1+m_2)}}$$

90 ••

Picture the Problem Because the two-particle system has zero initial energy and zero initial linear momentum; we can use energy and momentum conservation to obtain simultaneous equations in the variables r, v_1 and v_2. We'll assume that initial separation distance of the particles and their final separation r *is large compared to the size of the particles* so that we can treat them as though they are point particles.

Use conservation of energy to relate the speeds of the particles when their separation distance is r:

$$E_i = E_f$$

or

$$0 = \tfrac{1}{2}m_1v_1^2 + \tfrac{1}{2}m_2v_2^2 - \frac{Gm_1m_2}{r} \qquad (1)$$

Use conservation of linear momentum to obtain a second relationship between the speeds of the particles and their masses:

$$p_i = p_f$$

or

$$0 = m_1v_1 + m_2v_2 \qquad (2)$$

Solve equation (2) for v_1 and substitute in equation (1) to obtain:

$$v_2^2\left(m_2+\frac{m_2^2}{m_1}\right)=\frac{2Gm_1m_2}{r} \qquad (3)$$

Solve equation (3) for v_2:

$$\boxed{v_2=\sqrt{\frac{2Gm_1^2}{r(m_1+m_2)}}}$$

Solve equation (2) for v_1 and substitute for v_2 to obtain:

$$\boxed{v_1=\sqrt{\frac{2Gm_2^2}{r(m_1+m_2)}}}$$

***91 ••**

Picture the Problem We can find the orbital speeds of the planets from their distance from the center of mass of the system and the period of their motion. Application of Kepler's 3rd law will allow us to express the period of their motion T in terms of the effective mass of the system … which we can find from its definition.

Express the orbital speeds of the planets in terms of their period T:

$$v=\frac{2\pi R}{T}$$

where R is the distance to the center of mass of the four-planet system.

Apply Kepler's 3rd law to express the period of the planets:

$$T=\sqrt{\frac{4\pi^2}{GM_{\text{eff}}}R^3}$$

where M_{eff} is the effective mass of the four planets.

Substitute to obtain:

$$v=\frac{2\pi R}{\sqrt{\frac{4\pi^2}{GM_{\text{eff}}}R^3}}=\sqrt{\frac{GM_{\text{eff}}}{R}}$$

The distance of each planet from the effective mass is:

$$R=\frac{a}{\sqrt{2}}$$

Find M_{eff} from its definition:

$$\frac{1}{M_{\text{eff}}}=\frac{1}{M}+\frac{1}{M}+\frac{1}{M}+\frac{1}{M}$$

and

$$M_{\text{eff}}=\tfrac{1}{4}M$$

Substitute for R and M_{eff} to obtain:

$$\boxed{v=\sqrt{\frac{\sqrt{2}GM}{4a}}}$$

92 ••

Picture the Problem Let *r* represent the separation of the particle from the center of the earth and assume a uniform density for the earth. The work required to lift the particle from the center of the earth to its surface is the integral of the gravitational force function. This function can be found from the law of gravity and by relating the mass of the earth between the particle and the center of the earth to the earth's mass. We can use the work-kinetic energy theorem to find the speed with which the particle, when released from the surface of the earth, will strike the center of the earth. Finally, the energy required for the particle to escape the earth from the center of the earth is the sum of the energy required to get it to the surface of the earth and the kinetic energy it must have to escape from the surface of the earth.

(*a*) Express the work required to lift the particle from the center of the earth to the earth's surface:

$$W = \int_0^{R_E} F\,dr \qquad (1)$$

where *F* is the gravitational force acting on the particle.

Using the law of gravity, express the force acting on the particle as a function of its distance from the center of the earth:

$$F = \frac{GmM}{r^2} \qquad (2)$$

where *M* is the mass of a sphere whose radius is *r*.

Express the ratio of M to M_E:

$$\frac{M}{M_E} = \frac{\rho\left(\frac{4}{3}\pi r^3\right)}{\rho\left(\frac{4}{3}\pi R_E^3\right)} \Rightarrow M = M_E\frac{r^3}{R_E^3}$$

Substitute for *M* in equation (2) to obtain:

$$F = \frac{GmM_E}{R_E^3}r = \frac{mgR_E^2}{R_E^3}r = \frac{mg}{R_E}r$$

Substitute for *F* in equation (1) and evaluate the integral:

$$W = \frac{mg}{R_E}\int_0^{R_E} r\,dr = \boxed{\frac{gmR_E}{2}}$$

(*b*) Use the work-kinetic energy theorem to relate the kinetic energy of the particle as it reaches the center of the earth to the work done on it in moving it to the surface of the earth:

$$W = \Delta K = \tfrac{1}{2}mv^2$$

Substitute for *W* and solve for *v*:

$$v = \boxed{\sqrt{gR_E}}$$

(*c*) Express the total energy required for the particle to escape when projected from the center of the earth:

$$E_{esc} = W + \tfrac{1}{2}mv_e^2 = \tfrac{1}{2}mv_{esc}^2$$

where v_e is the escape speed from the surface of the earth.

Substitute for W and solve for v_{esc}:

$$v_{esc} = \sqrt{3gR_E}$$

Substitute numerical values and evaluate v_{esc}:

$$v_{esc} = \sqrt{3(9.81\,\text{N/kg})(6.37\times10^6\,\text{m})} = \boxed{13.7\,\text{km/s}}$$

93 ••

Picture the Problem We need to find the gravitational field in three regions: $r < R_1$, $R_1 < r < R_2$, and $r > R_2$.

For $r < R_1$:

$$g = \boxed{0}$$

For $r > R_2$, $g(r)$ is the field of a mass M centered at the origin:

$$g(r) = \boxed{\frac{GM}{r^2}}$$

For $R_1 < r < R_2$, $g(r)$ is determined by the mass within the shell of radius r:

$$g(r) = \frac{Gm}{r^2} \qquad (1)$$

where $m = \tfrac{4}{3}\pi\rho\left(r^3 - R_1^3\right) \qquad (2)$

Express the density of the spherical shell:

$$\rho = \frac{M}{V} = \frac{M}{\tfrac{4}{3}\pi\left(R_2^3 - R_1^3\right)}$$

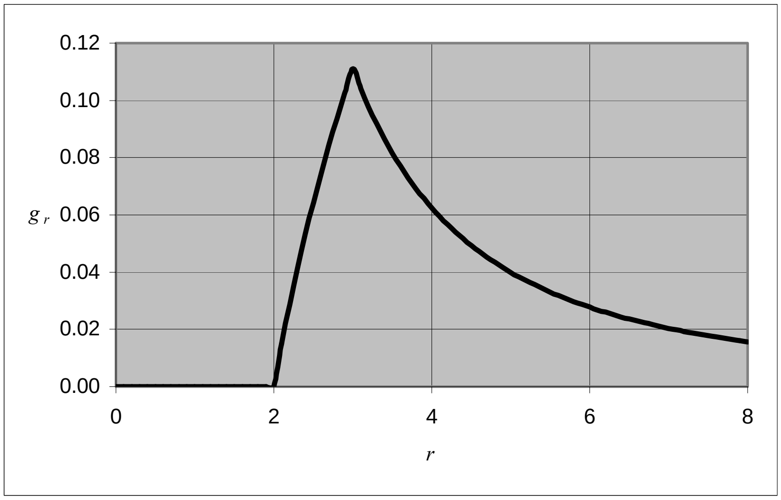
Substitute for ρ in equation (2) and simplify to obtain:

$$m = \frac{M\left(r^3 - R_1^3\right)}{R_2^3 - R_1^3}$$

Substitute for m in equation (1) to obtain:

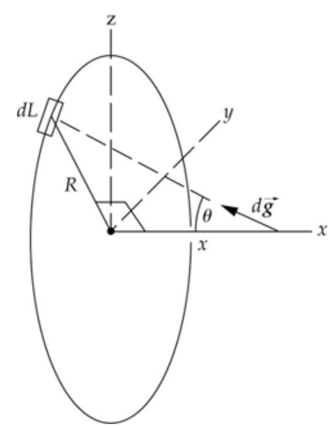
$$g(r) = \boxed{\frac{GM\left(r^3 - R_1^3\right)}{r^2\left(R_2^3 - R_1^3\right)}}$$

A graph of g_r with $R_1 = 2$, $R_2 = 3$, and $GM = 1$ follows:



94 ••

Picture the Problem A ring of radius R is shown to the right. Choose a coordinate system in which the origin is at the center of the ring and x axis is as shown. An element of length dL and mass dm is responsible for the field dg at a distance x from the center of the ring. We can express the x component of dg and then integrate over the circumference of the ring to find the total field as a function of x.



(*a*) Express the differential gravitational field at a distance x from the center of the ring in terms of the mass of elemental length dL:

$$dg = \frac{Gdm}{R^2 + x^2}$$

Relate the mass of the element to its length:

$$dm = \lambda\, dL$$

where λ is the linear density of the ring.

Substitute to obtain:

$$dg = \frac{G\lambda\, dL}{R^2 + x^2}$$

By symmetry, the y and z components of g vanish. Express the x component of dg:

$$dg_x = dg\cos\theta$$

$$= \frac{G\lambda\, dL}{R^2 + x^2}\cos\theta$$

Referring to the figure, express $\cos\theta$:

$$\cos\theta = \frac{x}{\sqrt{R^2 + x^2}}$$

Substitute to obtain:

$$dg_x = \frac{G\lambda\, dL}{R^2 + x^2} \times \frac{x}{\sqrt{R^2 + x^2}} = \frac{G\lambda\, x dL}{\left(R^2 + x^2\right)^{3/2}}$$

Because $\lambda = \dfrac{M}{2\pi R}$:

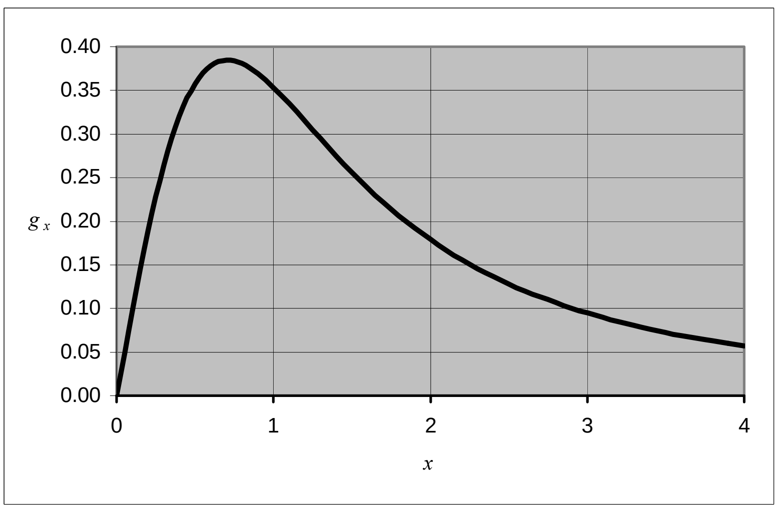
$$dg_x = \frac{GM\, x dL}{2\pi R\left(R^2 + x^2\right)^{3/2}}$$

Integrate to find $g(x)$:

$$g(x) = \frac{GM\, x}{2\pi R\left(R^2 + x^2\right)^{3/2}} \int_0^{2\pi R} dL$$

$$= \boxed{\frac{GM}{\left(R^2 + x^2\right)^{3/2}}\, x}$$

A plot of g_x is shown below. The curve is normalized for $R = 1$ and $GM = 1$.



(*b*) Differentiate $g(x)$ with respect to x and set the derivative equal to zero to identify extreme values:

$$\frac{dg}{dx} = GM\left[\frac{\left(x^2 + R^2\right)^{3/2} - x\left(\frac{3}{2}\right)\left(x^2 + R^2\right)^{1/2}(2x)}{\left(R^2 + x^2\right)^3}\right] = 0 \text{ for extrema}$$

Simplify to obtain:

$$\left(x^2 + R^2\right)^{3/2} - 3x^2\left(x^2 + R^2\right)^{1/2} = 0$$

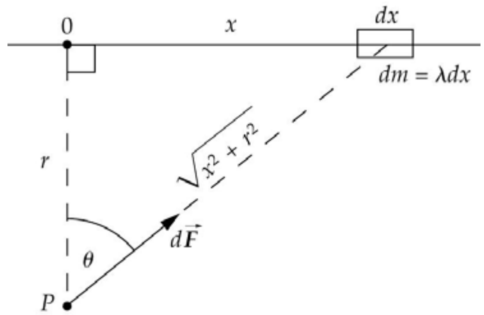
Solve for x to obtain:

$$x = \boxed{\pm\frac{R}{\sqrt{2}}}$$

Because the curve is concave downward, we can conclude that this result corresponds to a maximum. Note that this result agrees with our graphical maximum.

95 •••

Picture the Problem The diagram shows a segment of the wire of length dx and mass $dm = \lambda dx$ at a distance x from the origin of our coordinate system. We can find the magnitude of the gravitational field at a distance r from the wire from the resultant gravitational force acting on a particle of mass m' located at point P and then integrating over the length of the wire.



Express the gravitational force acting on a particle of mass m' at a distance r from the wire due to the segment of the wire of length dx:

$$dF = m'dg$$

or

$$dg = \frac{dF}{m'}$$

Using Newton's law of gravity, express dF:

$$dF = \frac{Gm'\lambda dx}{R^2}$$

or, because $R^2 = x^2 + r^2$,

$$dF = \frac{Gm'\lambda dx}{x^2 + r^2}$$

Substitute and simplify to express the gravitational field due to the segment of the wire of length dx:

$$dg = \frac{G\lambda dx}{x^2 + r^2}$$

By symmetry, the segment on the opposite side of the origin at the same distance from the origin will cancel out all but the radial component of the field, so the gravitational field will be given by:

$$\begin{aligned} dg &= \frac{G\lambda dx}{x^2 + r^2}\cos\theta \\ &= \frac{G\lambda dx}{x^2 + r^2}\frac{r}{\sqrt{x^2 + r^2}} \\ &= \frac{G\lambda r}{\left(x^2 + r^2\right)^{3/2}}dx \end{aligned}$$

Integrate dg from $x' = -\infty$ to $x' = +\infty$ to obtain:

$$g = \int_{-\infty}^{\infty}\frac{G\lambda r}{\left(x'^2 + r^2\right)^{3/2}}dx' = 2G\lambda\int_{0}^{\infty}\frac{r}{\left(x'^2 + r^2\right)^{3/2}}dx' = \frac{2G\lambda}{r}\left[\frac{x}{\sqrt{x'^2 + r^2}}\right]_0^{\infty} = \boxed{\frac{2G\lambda}{r}}$$

96 •••

Picture the Problem We can use the relationship between the angular velocity of an orbiting object and its tangential velocity to express the speeds v_{in} and v_{out} of the innermost and outermost portions of the ring. In part (*b*) we can use Newton's law of gravity, in conjunction with the 2nd law of motion, to relate the tangential speed of a chunk of the ring to the gravitational force acting on it. As in part (*a*), once we know v_{in} and v_{out}, we can express the difference between them to obtain the desired results.

(*a*) Express the speed of a point in the ring at a distance R' from the center of the planet under the assumption that the ring is solid and rotates with an angular velocity ω:

$$v(R') = \omega R$$

Express the speeds v_{in} and v_{out} of the innermost and outermost portions of the ring:

$$v_{in} = \left(R - \tfrac{1}{2}r\right)\omega$$

and

$$v_{out} = \left(R + \tfrac{1}{2}r\right)\omega$$

Express the difference between v_{out} and v_{in}:

$$v_{out} - v_{in} = \left(R + \tfrac{1}{2}r\right)\omega - \left(R - \tfrac{1}{2}r\right)\omega$$

$$= \omega r = \frac{v}{R}r = \boxed{v\frac{r}{R}}$$

(*b*) Assume that a chunk of the ring is moving in a circular orbit around the center of the planet under the force of gravity. Then, we can find its velocity by equating the force of gravity to the centripetal force needed to keep it in orbit:

$$\frac{GMm}{R'^2} = \frac{mv^2}{R'}$$

or

$$v = \sqrt{\frac{GM}{R'}}$$

where M is the mass of the planet and R' the distance from the center.

Substitute for R' to express v_{out}:

$$v_{out} = \sqrt{\frac{GM}{R + \frac{1}{2}r}} = \sqrt{\frac{GM}{R\left(1 + \frac{1}{2}\frac{r}{R}\right)}}$$

$$= \sqrt{\frac{GM}{R}}\left(1 + \frac{1}{2}\frac{r}{R}\right)^{-1/2}$$

Expand binomially to obtain:

$$v_{out} = \sqrt{\frac{GM}{R}}\left(1 - \frac{1}{2}\frac{1}{2}\frac{r}{R} + \text{higher order terms}\right)$$

$$\approx \sqrt{\frac{GM}{R}}\left(1 - \frac{1}{4}\frac{r}{R}\right)$$

Proceed similarly to obtain, for v_{in}:

$$v_{\text{in}} \approx \sqrt{\frac{GM}{R}}\left(1+\frac{1}{4}\frac{r}{R}\right)$$

Express the difference between v_{out} and v_{in}:

$$v_{\text{out}} - v_{\text{in}} \approx \sqrt{\frac{GM}{R}}\left(1-\frac{1}{4}\frac{r}{R}\right) - \sqrt{\frac{GM}{R}}\left(1+\frac{1}{4}\frac{r}{R}\right) = \sqrt{\frac{GM}{R}}\left(-\frac{1}{2}\frac{r}{R}\right)$$

and, because $v = \sqrt{\dfrac{GM}{R}}$, $\boxed{v_{\text{out}} - v_{\text{in}} \approx -\dfrac{1}{2}\dfrac{r}{R}v}$

97 •••

Picture the Problem Let $U = 0$ at $x = \infty$. The potential energy of an element of the stick dm and the point mass m_0 is given by the definition of gravitational potential energy: $dU = -Gm_0dm/r$ where r is the separation of dm and m_0.

(*a*) Express the potential energy of the masses m_0 and dm:

$$dU = -\frac{Gm_0dm}{x_0 - x}$$

The mass dm is proportional to the size of the element dx:

$$dm = \lambda\, dx$$

where $\lambda = \dfrac{M}{L}$.

Substitute these results to express dU in terms of x:

$$dU = -\frac{Gm_0\lambda\, dx}{x_0 - x} = \boxed{-\frac{GMm_0\, dx}{L(x_0 - x)}}$$

(*b*) Integrate to find the total potential energy for the system:

$$U = -\frac{GMm_0}{L}\int_{-L/2}^{L/2}\frac{dx}{x_0 - x} = \frac{GMm_0}{L}\left[\ln\left(x_0 - \frac{L}{2}\right) - \ln\left(x_0 + \frac{L}{2}\right)\right]$$

$$= \boxed{-\frac{GMm_0}{L}\ln\left(\frac{x_0 + L/2}{x_0 - L/2}\right)}$$

(*c*) Because x_0 is a general point along the x axis:

$$F(x_0) = -\frac{dU}{dx_0} = \frac{Gmm_0}{L}\left[\frac{1}{x_0 + \frac{L}{2}} - \frac{1}{x_0 - \frac{L}{2}}\right]$$

Simplify this expression to obtain:

$$F(x_0) = \boxed{-\frac{Gmm_0}{x^2 - L^2/4}}$$

in agreement with the result of Example 11-8.

***98 •••**

Picture the Problem Choose a mass element *dm* of the rod of thickness *dx* at a distance *x* from the origin. All such elements of the rod experience a gravitational force *dF* due to presence of the sphere centered at the origin. We can find the total gravitational force of attraction experienced by the rod by integrating *dF* from *x* = *a* to *x* = *a* + *L*.

Express the gravitational force *dF* acting on the element of the rod of mass *dm*:

$$dF = \frac{GMdm}{x^2}$$

Express *dm* in terms of the mass *m* and length *L* of the rod:

$$dm = \frac{m}{L}dx$$

Substitute to obtain:

$$dF = \frac{GMm}{L}\frac{dx}{x^2}$$

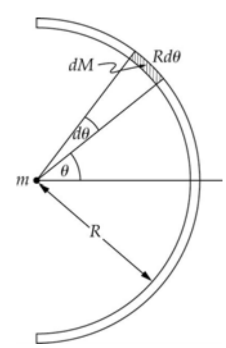
Integrate *dF* from *x* = *a* to *x* = *a* + *L* to find the total gravitational force acting on the rod:

$$F = \frac{GMm}{L}\int_a^{a+L} x^{-2}dx = -\frac{GMm}{L}\left[\frac{1}{x}\right]_a^{a+L}$$

$$= \boxed{\frac{GMm}{a(a+L)}}$$

99 •••

Picture the Problem The semicircular rod is shown in the figure. We'll use an element of length $Rd\theta = \frac{L}{\pi}d\theta$ whose mass *dM* is $\frac{M}{\pi}d\theta$. By symmetry, $F_y = 0$. We'll first find dF_x and then integrate over θ from $-\pi/2$ to $\pi/2$.



Express dF_x:

$$dF_x = \frac{GmdM}{R^2} = \frac{GMm}{\pi\left(\frac{L}{\pi}\right)^2}d\theta\cos\theta$$

Integrate dF_x over θ from $-\pi/2$ to $\pi/2$:

$$F_x = \frac{\pi\, GMm}{L^2}\int_{-\pi/2}^{\pi/2}\cos\theta\, d\theta = \frac{2\pi\, GMm}{L^2}$$

Substitute numerical values and evaluate F_x:

$$F_x = \frac{2\pi\left(6.6726\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(20\,\text{kg}\right)\left(0.1\,\text{kg}\right)}{\left(5\,\text{m}\right)^2} = \boxed{33.5\,\text{pN}}$$

***100** •••

Picture the Problem We can begin by expressing the forces exerted by the sun and the moon on a body of water of mass *m* and taking the ratio of these forces. In (*b*) we'll simply follow the given directions and in (*c*) we can approximate differential quantities with finite quantities to establish the given ratio.

(*a*) Express the force exerted by the sun on a body of water of mass *m*:

$$F_\text{S} = \frac{GM_\text{S}m}{r_\text{S}^2}$$

Express the force exerted by the moon on a body of water of mass *m*:

$$F_\text{m} = \frac{GM_\text{m}m}{r_\text{m}^2}$$

Divide the first of these equations by the second and simplify to obtain:

$$\frac{F_\text{S}}{F_\text{m}} = \boxed{\frac{M_\text{S}r_\text{m}^2}{M_\text{m}r_\text{S}^2}}$$

Substitute numerical values and evaluate this ratio:

$$\frac{F_\text{S}}{F_\text{m}} = \frac{\left(1.99\times10^{30}\ \text{kg}\right)\left(3.84\times10^{8}\ \text{m}\right)^2}{\left(7.36\times10^{22}\ \text{kg}\right)\left(1.50\times10^{11}\ \text{m}\right)^2} = \boxed{177}$$

(*b*) Find $\dfrac{dF}{dr}$:

$$\frac{dF}{dr} = -\frac{2Gm_1m_2}{r^3} = -2\frac{F}{r}$$

Solve for the ratio $\dfrac{dF}{F}$:

$$\frac{dF}{F} = \boxed{-2\frac{dr}{r}}$$

(*c*) Express the change in force ΔF for a small change in distance Δr:

$$\Delta F = -2\frac{F}{r}\Delta r$$

Express ΔF_S:

$$\Delta F_S = -2\frac{\frac{GmM_S}{r_S^2}}{r_S}\Delta r_S = -2\frac{GmM_S}{r_S^3}\Delta r_S$$

Express ΔF_m:

$$\Delta F_m = -2\frac{GmM_m}{r_m^3}\Delta r_m$$

Divide the first of these equations by the second and simplify:

$$\frac{\Delta F_S}{\Delta F_m} = \frac{\frac{M_S}{r_S^3}\Delta r_S}{\frac{M_m}{r_m^3}\Delta r_m} = \frac{M_S r_m^3}{M_m r_S^3}\frac{\Delta r_S}{\Delta r_m} = \boxed{\frac{M_S r_m^3}{M_m r_S^3}}$$

because $\frac{\Delta r_S}{\Delta r_m} = 1$.

Substitute numerical values and evaluate this ratio:

$$\frac{\Delta F_S}{\Delta F_m} = \frac{(1.99\times10^{30}\text{ kg})(3.84\times10^{8}\text{ m})^3}{(7.36\times10^{22}\text{ kg})(1.50\times10^{11}\text{ m})^3} = \boxed{0.454}$$

101 ••

Picture the Problem Let M_{NS} be the mass of the Neutron Star and m the mass of each robot. We can use Newton's law of gravity to express the difference in the tidal-like forces acting on the coupled robots. Expanding the expression for the force on the robot further from the Neutron Star binomially will lead us to an expression for the distance at which the breaking tension in the connecting cord will be exceeded.

(*a*) The gravitational force is greater on the lower robot, so if it were not for the cable its acceleration would be greater than that of the upper robot, and they would separate. In opposing this separation the cable is stressed.

(*b*) Letting the separation of the two robots be Δr, and the distance from the center of the star to the lower robot be r, use Newton's law of gravity to express the difference in the forces acting on the robots:

$$F_{\text{tide}} = \frac{GM_{\text{NS}}m}{r^2} - \frac{GM_{\text{NS}}m}{(r+\Delta r)^2}$$

$$= GM_{\text{NS}}m\left[\frac{1}{r^2} - \frac{1}{r^2\left(1+\frac{\Delta r}{r}\right)^2}\right]$$

$$= \frac{GM_{\text{NS}}m}{r^2}\left[1-\left(1+\frac{\Delta r}{r}\right)^{-2}\right]$$

Expand the expression in the square brackets binomially to obtain:

$$1-\left(1+\frac{\Delta r}{r}\right)^{-2} \approx 1-\left(1-2\frac{\Delta r}{r}\right)$$

$$= 2\frac{\Delta r}{r}$$

Substitute to obtain:

$$F_{\text{tide}} \approx \frac{2GM_{\text{NS}}m}{r^3}\Delta r$$

Letting F_B be the breaking tension of the cord, substitute for F_{tide} and solve for the value of r corresponding to the breaking strain being exceeded:

$$r = \sqrt[3]{\frac{2GM_{\text{NS}}m}{F_B}\Delta r}$$

Substitute numerical values and evaluate r:

$$r = \sqrt[3]{\frac{2\left(6.673\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2\right)\left(1.99\times10^{30}\,\text{kg}\right)(1\,\text{kg})}{25\,\text{kN}}(1\,\text{m})} = \boxed{220\text{ km}}$$

Chapter 12
Static Equilibrium and Elasticity

Conceptual Problems

1 •

(*a*) False. The conditions $\sum_i \vec{F}_i = 0$ and $\sum_i \vec{\tau}_i = 0$ must be satisfied.

(*b*) True. The necessary and sufficient conditions for static equilibrium are $\sum_i \vec{F}_i = 0$ and $\sum_i \vec{\tau}_i = 0$.

(*c*) True. The conditions $\sum_i \vec{F}_i = 0$ and $\sum_i \vec{\tau}_i = 0$ must be satisfied.

(*d*) False. An object is in equilibrium provided the conditions $\sum_i \vec{F}_i = 0$ and $\sum_i \vec{\tau}_i = 0$ are satisfied.

2 •

False. The location of the center of gravity depends on the mass distribution.

3 •

No. The definition of the center of gravity does not require that there be any material at its location.

4 •

Determine the Concept When the acceleration of gravity is not constant over an object, the center of gravity is the pivot point for balance.

5 ••

Determine the Concept This technique works because the center of mass must be directly under the balance point. Thus, a line drawn straight downward will pass through the center of mass, and another line drawn straight downward when the figure is hanging from another point will also pass through the center of mass. The center of mass is where the lines cross.

***6** •

Determine the Concept No. Because the floor can exert no horizontal force, neither can the wall. Consequently, the friction force between the wall and the ladder is zero regardless of the coefficient of friction between the wall and the ladder.

7 •

Determine the Concept We know that equal lengths of aluminum and steel wire of the same diameter will stretch different amounts when subjected to the same tension. Also, because we are neglecting the mass of the wires, the tension in them is independent of which one is closer to the roof and depends only on W. $\boxed{(b) \text{ is correct.}}$

8 •

Determine the Concept Yes; if it were otherwise, angular momentum conservation would depend on the choice of coordinates.

***9** •

Determine the Concept The condition that the bar is in rotational equilibrium is that the net torque acting on it be zero; i.e., $R_1M_1 = R_2M_2$. This condition is satisfied provided $R_1 = R_2$ and $M_1 = M_2$. $\boxed{(c) \text{ is correct.}}$

10 ••

Determine the Concept You cannot stand up because your body's center of gravity must be above your feet.

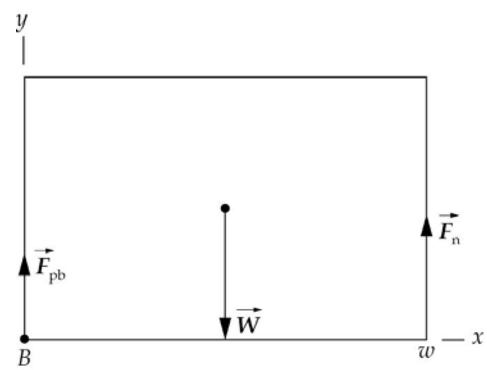
***11** ••

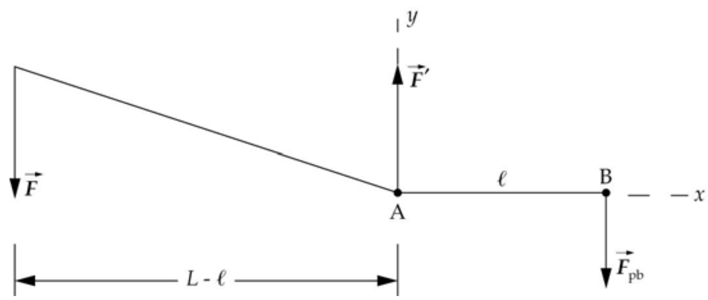
Determine the Concept The tensile strengths of stone and concrete are at least an order of magnitude lower than their compressive strengths, so you want to build compressive structures to match their properties.

Estimation and Approximation

12 ••

Picture the Problem The diagram to the right shows the forces acting on the crate as it is being lifted at its left end. Note that when the crowbar lifts the crate, only half the weight of the crate is supported by the bar. Choose the coordinate system shown and let the subscript ″pb″ refer to the pry bar. The diagram below shows the forces acting on the pry bar as it is being used to lift the end of the crate.





Assume that the maximum force F' you can apply is 500 N (about 110 lb). Let ℓ be the distance between the points of contact of the steel bar with the floor and the crate, and let L be the total length of the bar. Lacking information regarding the bend in pry bar at the fulcrum, we'll assume that it is small enough to be negligible. We can apply the condition for rotational equilibrium to the pry bar and a condition for translational equilibrium to the crate when its left end is on the verge of lifting.

Apply $\sum F_y = 0$ to the crate: $$F_{\text{pb}} - W + F_{\text{n}} = 0 \quad (1)$$

Apply $\sum \vec{\tau} = 0$ to the crate about an axis through point B and perpendicular to the plane of the page to obtain: $$wF_{\text{n}} - \tfrac{1}{2}wW = 0$$

Solve for F_{n}: $$F_{\text{n}} = \tfrac{1}{2}W$$
as noted in Picture the Problem.

Solve equation (1) for F_{pb} and substitute for F_{n} to obtain: $$F_{\text{pb}} = W - \tfrac{1}{2}W = \tfrac{1}{2}W$$

Apply $\sum \vec{\tau} = 0$ to the pry bar about an axis through point A and perpendicular to the plane of the page to obtain: $$F(L-\ell) - \ell F_{\text{pb}} = 0$$

Solve for L: $$L = \ell\left(1 + \frac{F_{\text{pb}}}{F}\right)$$

Substitute for F_{pb} to obtain: $$L = \ell\left(1 + \frac{W}{2F}\right)$$

Substitute numerical values and evaluate L:

$$L = (0.1\,\text{m})\left(1 + \frac{4500\,\text{N}}{2(500\,\text{N})}\right) = \boxed{55.0\,\text{cm}}$$

***13 ••**

Picture the Problem We can derive this expression by imagining that we pull on an area A of the given material, expressing the force each spring will experience, finding the fractional change in length of the springs, and substituting in the definition of Young's modulus.

(*a*) Express Young's modulus:

$$Y = \frac{F/A}{\Delta L/L} \qquad (1)$$

Express the elongation ΔL of each spring:

$$\Delta L = \frac{F_s}{k} \qquad (2)$$

Express the force F_s each spring will experience as a result of a force F acting on the area A:

$$F_s = \frac{F}{N}$$

Express the number of springs N in the area A:

$$N = \frac{A}{a^2}$$

Substitute to obtain:

$$F_s = \frac{Fa^2}{A}$$

Substitute in equation (2) to obtain, for the extension of one spring:

$$\Delta L = \frac{Fa^2}{kA}$$

Assuming that the springs extend/compress linearly, express the fractional extension of the springs:

$$\frac{\Delta L_{tot}}{L} = \frac{\Delta L}{a} = \frac{1}{a}\frac{Fa^2}{kA} = \frac{Fa}{kA}$$

Substitute in equation (1) and simplify:

$$Y = \frac{\frac{F}{A}}{\frac{Fa}{kA}} = \boxed{\frac{k}{a}}$$

(*b*) From our result in part (*a*):

$$k = Ya$$

From Table 12-1:

$$Y = 200\text{GN/m}^2 = 2\times10^{11}\ \text{N/m}^2$$

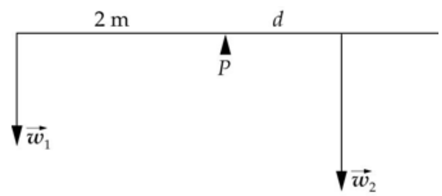
Assuming that $a \sim 1$ nm, evaluate k:

$$k = \left(2\times10^{11}\ \text{N/m}^2\right)\left(10^{-9}\ \text{m}\right) = \boxed{200\,\text{N/m}}$$

Conditions for Equilibrium

14 •

Picture the Problem Let w_1 represent the weight of the 28-kg child sitting at the left end of the board, w_2 the weight of the 40-kg child, and d the distance of the 40-kg child from the pivot point. We can apply the condition for rotational equilibrium to find d.



Apply $\sum \vec{\tau} = 0$ about an axis through the pivot point P:

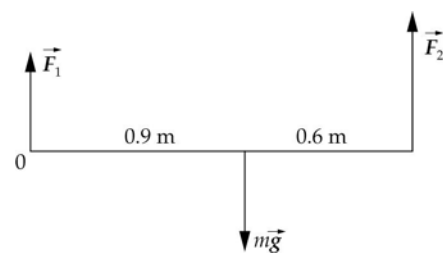
$$w_1(2\,m) - w_2 d = 0$$

Solve for and evaluate d:

$$d = \frac{w_1(2\,\text{m})}{w_2} = \frac{(28\,\text{kg})g(2\,\text{m})}{(40\,\text{kg})g} = \boxed{1.4\,\text{m}}$$

15 •

Picture the Problem Let F_1 represent the force exerted by the floor on Misako's feet, F_2 the force exerted on her hands, and m her mass. We can apply the condition for rotational equilibrium to find F_2.



Apply $\sum \vec{\tau} = 0$ about an axis through point 0:

$$F_2(1.5\,\text{m}) - mg(0.9\,\text{m}) = 0$$

Solve for F_2:

$$F_2 = \frac{mg(0.9\,\text{m})}{1.5\,\text{m}}$$

Substitute numerical values and evaluate F_2:

$$F_2 = \frac{(54\,\text{kg})(9.81\,\text{m/s}^2)(0.9\,\text{m})}{1.5\,\text{m}}$$

$$= \boxed{318\,\text{N}}$$

***16** •

Picture the Problem Let F represent the force exerted by Misako's biceps. To find F we apply the condition for rotational equilibrium about a pivot chosen at the tip of her elbow.

Apply $\sum \vec{\tau} = 0$ about an axis

$$(5\,\text{cm})F - (28\,\text{cm})(18\,\text{N}) = 0$$

through the pivot:

Solve for F:

$$F = \frac{(28\,\text{cm})(18\,\text{N})}{5\,\text{cm}} = \boxed{101\,\text{N}}$$

17 •

Picture the Problem Choose a coordinate system in which upward is the positive y direction and to the right is the positive x direction and use the conditions for translational equilibrium.

(a) Apply $\sum \vec{F} = 0$ to the forces acting on the tip of the crutch:

$$\sum F_x = -f_s + F_c \sin\theta = 0 \quad (1)$$

and

$$\sum F_y = F_n - F_c \cos\theta = 0 \quad (2)$$

Solve equation (2) for F_n and assuming that $f_s = f_{s,max}$, obtain:

$$f_s = f_{s,max} = \mu_s F_n = \mu_s F_c \cos\theta$$

Substitute in equation (1) and solve for μ_s:

$$\mu_s = \boxed{\tan\theta}$$

(b) Taking long strides requires a large coefficient of static friction because θ is large for long strides.

(c) If μ_s is small, i.e., there is ice on the surface, θ must be small to avoid slipping.

The Center of Gravity

18 •

Picture the Problem Let the weight of the automobile be w. Choose a coordinate system in which the origin is at the point of contact of the front wheels with the ground and the positive x axis includes the point of contact of the rear wheels with the ground. Apply the definition of the center of gravity to find its location.

Use the definition of the center of gravity:

$$x_{cg}W = \sum_i w_i x_i$$
$$= 0.58w(0) + 0.42w(2\,\text{m})$$
$$= (0.84\,\text{m})w$$

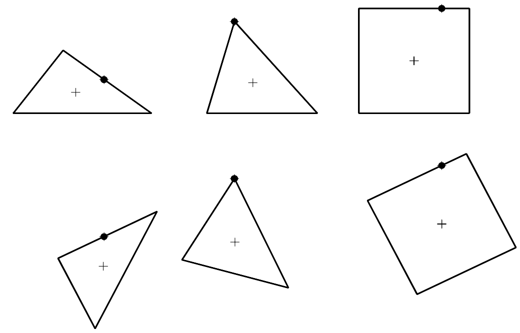
or, because $W = w$, $x_{cg}(w) = (0.84\,\text{m})w$

Solve for x_{cg}:

$$x_{cg} = \boxed{0.84\,\text{m}}$$

***19 •**

Picture the Problem The figures are shown on the right. The center of mass for each is indicated by a small +. At static equilibrium, the center of gravity is directly below the point of support.



20 ••

Picture the Problem Using the coordinate system indicated in the figure, we can apply the definition of the center of gravity to determine x_{cg} and y_{cg}.

Apply the definition of the center of gravity to find x_{cg}:

$$\begin{aligned} x_{cg}W &= \sum_i w_i x_i \\ &= (40\,\text{N})\left(\tfrac{1}{2}a\right) + (60\,\text{N})\left(\tfrac{1}{2}a\right) \\ &\quad + (30\,\text{N})\left(\tfrac{3}{2}a\right) + (50\,\text{N})\left(\tfrac{3}{2}a\right) \\ &= (170\,\text{N})a \end{aligned}$$

or, because $W = 180$ N,

$$x_{cg}(180\,\text{N}) = (170\,\text{N})a$$

Solve for x_{cg}:

$$x_{cg} = \frac{170\,\text{N}}{180\,\text{N}}a = 0.944a$$

Apply the definition of the center of gravity to find y_{cg}:

$$\begin{aligned} y_{cg}W &= \sum_i w_i y_i \\ &= (40\,\text{N})\left(\tfrac{1}{2}a\right) + (60\,\text{N})\left(\tfrac{3}{2}a\right) \\ &\quad + (30\,\text{N})\left(\tfrac{3}{2}a\right) + (50\,\text{N})\left(\tfrac{1}{2}a\right) \\ &= (180\,\text{N})a \end{aligned}$$

or, because $W = 180$ N,

$$y_{cg}(180\,\text{N}) = (180\,\text{N})a$$

Solve for y_{cg}:

$$y_{cg} = a$$

The coordinates of the center of gravity are:

$$(x_{cg}, y_{cg}) = \boxed{(0.944a, a)}$$

21 ••

Picture the Problem Let the origin of the coordinate system be at the lower left corner of the plate and the positive x direction be to the right. Let a and b be the length and width of the plate. Let σ be the mass per unit area of the plate. Then the weight of the plate is given by $w = ab\sigma g$ and that of the matter missing from the hole is $-\pi R^2\sigma g$. Noting that, by symmetry, $y_{cg} = b/2$, we can apply the definition of the center of gravity to find x_{cg}.

Apply the definition of the center of gravity to find x_{cg}:

$$x_{cg}W = \sum_i w_i x_i = (ab\sigma g)\left(\tfrac{1}{2}a\right) - \left(\pi R^2\sigma g\right)(a - R)$$

or, because

$$W = w_{plate} - w_{hole} = ab\sigma g - \pi R^2\sigma g,$$

$$x_{cg}\left(ab\sigma g - \pi R^2\sigma g\right) = (ab\sigma g)\left(\tfrac{1}{2}a\right) - \left(\pi R^2\sigma\right)(a - R)$$

Solve for x_{cg}:

$$x_{cg} = \frac{\frac{1}{2}a^2b - \pi aR^2 + \pi R^3}{ab - \pi R^2}$$

The coordinates of the center of gravity are:

$$\left(x_{cg}, y_{cg}\right) = \boxed{\left(\frac{\frac{1}{2}a^2b - \pi aR^2 + \pi R^3}{ab - \pi R^2}, \tfrac{1}{2}b\right)}$$

Some Examples of Static Equilibrium

22 •

Picture the Problem We can use the given definition of the mechanical advantage of a lever and the condition for rotational equilibrium to show that $M = x/X$.

(*a*) Express the definition of mechanical advantage for a lever:

$$M = \frac{F}{f}$$

Apply the condition for rotational equilibrium to the lever:

$$xf - XF = 0$$

Solve for the ratio of F to f to obtain:

$$\frac{F}{f} = \frac{x}{X}$$

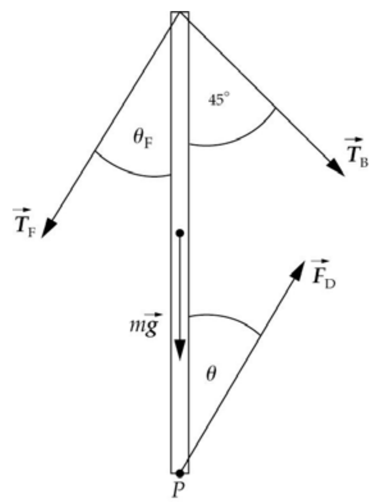
Substitute to obtain:

$$M = \boxed{\frac{x}{X}}$$

(*b*) A shorter moment arm for the applied force is useful when one wishes to move the load over a large distance using a short movement of the applied force.

23 •

Picture the Problem The force diagram shows the tension in the forestay, $\vec{T}_F$, the tension in the backstay, $\vec{T}_B$, the gravitational force on the mast $m\vec{g}$, and the force exerted by the deck, $\vec{F}_D$. Let the origin of the coordinate system be at the foot of the mast with the positive *x* direction to the right and the positive *y* direction upward. Because the mast is in equilibrium, we can apply the conditions for both translational and rotational equilibrium to find the tension in the backstay and the force that the deck exerts on the mast.



Apply $\sum\vec{\tau} = 0$ to the mast about an axis through its foot and solve for T_B:

$$(4.88\,\text{m})(1000\,\text{N})\sin\theta_F - (4.88\,\text{m})T_B\sin 45° = 0$$

and

$$T_B = \frac{(1000\,\text{N})\sin\theta_F}{\sin 45°}$$

Find θ_F, the angle of the forestay with the vertical:

$$\theta_F = \tan^{-1}\left(\frac{2.74\,\text{m}}{4.88\,\text{m}}\right) = 29.3°$$

Substitute to obtain:

$$T_B = \frac{(1000\,\text{N})\sin 29.3°}{\sin 45°} = \boxed{692\,\text{N}}$$

Apply the condition for translational equilibrium in the *x* direction to the mast:

$$\sum F_x = F_D\cos\theta + T_B\sin 45° - T_F\sin\theta_F = 0$$

or

$$F_D\cos\theta = (1000\,\text{N})\sin 29.3° - (692\,\text{N})\sin 45° \approx 0$$

Apply the condition for translational equilibrium in the *y* direction to the mast:

$$\sum F_y = F_D\sin\theta - T_F\cos\theta_F - T_B\cos 45° - mg = 0$$

or

$$F_D \sin\theta = (1000\,\text{N})\cos 29.3° + (692\,\text{N})\cos 45° + (120\,\text{kg})(9.81\,\text{m/s}^2) = 2539\,\text{N}$$

Because $F_D\cos\theta = 0$:

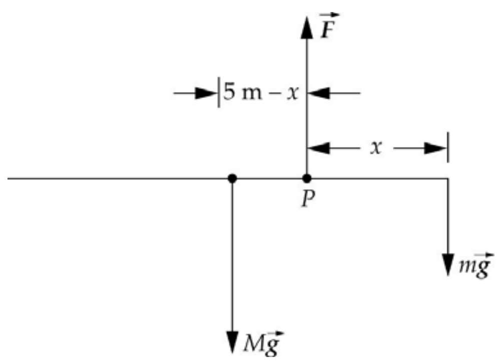
$$\theta = \boxed{90°},\ F_D = \boxed{2.54\,\text{kN}}$$

and

no block is required to prevent the mast from moving.

24 ••

Picture the Problem The diagram shows $M\vec{g}$, the weight of the beam, $m\vec{g}$, the weight of the student, and the force the ledge exerts $\vec{F}$, acting on the beam. Because the beam is in equilibrium, we can apply the condition for rotational equilibrium to the beam to find the location of the pivot point P that will allow the student to walk to the end of the beam.



Apply $\sum\vec{\tau} = 0$ about an axis through the pivot point P:

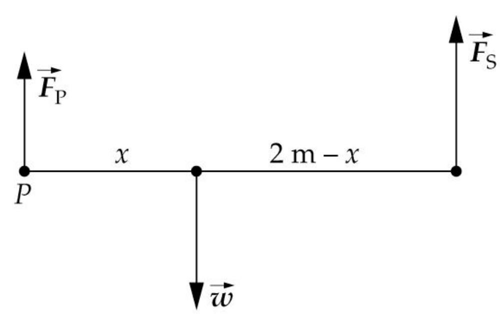
$$Mg(5\,\text{m} - x) - mgx = 0$$

Solve for x:

$$x = \frac{5M}{M+m} = \frac{5(300\,\text{kg})}{300\,\text{kg} + 60\,\text{kg}} = \boxed{4.17\,\text{m}}$$

***25** ••

Picture the Problem The diagram shows $\vec{w}$, the weight of the student, $\vec{F}_P$, the force exerted by the board at the pivot, and $\vec{F}_s$, the force exerted by the scale, acting on the student. Because the student is in equilibrium, we can apply the condition for rotational equilibrium to the student to find the location of his center of gravity.



Apply $\sum\vec{\tau} = 0$ about an axis

$$F_s(2\,\text{m}) - wx = 0$$

through the pivot point *P*:

Solve for *x*:

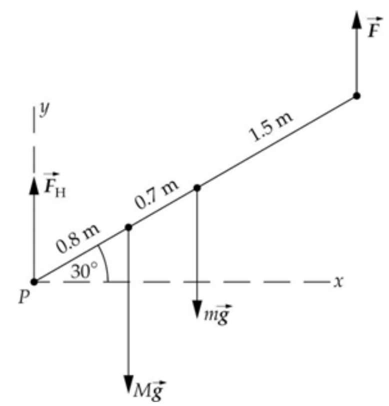
$$x = \frac{(2\,\text{m})F_s}{w}$$

Substitute numerical values and evaluate *x*:

$$x = \frac{(2\,\text{m})(250\,\text{N})}{(70\,\text{kg})(9.81\,\text{m/s}^2)} = \boxed{0.728\,\text{m}}$$

26 ••

Picture the Problem The diagram shows $m\vec{g}$, the weight of the board, $\vec{F}_H$, the force exerted by the hinge, $M\vec{g}$, the weight of the block, and $\vec{F}$, the force acting vertically at the right end of the board. Because the board is in equilibrium, we can apply the condition for rotational equilibrium to it to find the magnitude of $\vec{F}$.



(*a*) Apply $\sum \vec{\tau} = 0$ about an axis through the hinge:

$$F[(3\,\text{m})\cos 30°] - mg[(1.5\,\text{m})\cos 30°] - Mg[(0.8\,\text{m})\cos 30°] = 0$$

Solve for *F*:

$$F = \frac{m(1.5\,\text{m}) + M(0.8\,\text{m})}{3\,\text{m}}g$$

Substitute numerical values and evaluate *F*:

$$F = \frac{(5\,\text{kg})(1.5\,\text{m}) + (60\,\text{kg})(0.8\,\text{m})}{3\,\text{m}} \times (9.81\,\text{m/s}^2) = \boxed{181\,\text{N}}$$

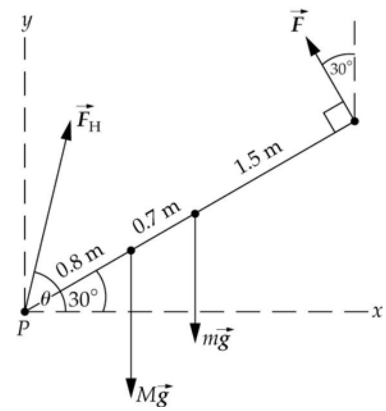
(*b*) Apply $\sum F_y = 0$ to the board:

$$F_H - Mg - mg + F = 0$$

Solve for and evaluate F_H:

$$F_H = Mg + mg - F = (M + m)g - F = (60\,\text{kg} + 5\,\text{kg})(9.81\,\text{m/s}^2) - 181\,\text{N} = \boxed{457\,\text{N}}$$

(*c*) The force diagram showing the force $\vec{F}$ acting at right angles to the board is shown to the right:



Apply $\sum \vec{\tau} = 0$ about the hinge:

$$F(3\,\text{m}) - mg[(1.5\,\text{m})\cos 30°] - Mg[(0.8\,\text{m})\cos 30°] = 0$$

Solve for *F*:

$$F = \frac{m(1.5\,\text{m}) + M(0.8\,\text{m})}{3\,\text{m}} g\cos 30°$$

Substitute numerical values and evaluate *F*:

$$F = \frac{(5\,\text{kg})(1.5\,\text{m}) + (60\,\text{kg})(0.8\,\text{m})}{3\,\text{m}} \times (9.81\,\text{m/s}^2)\cos 30° = \boxed{157\,\text{N}}$$

Apply $\sum F_y = 0$ to the board:

$$F_\text{H}\sin\theta - Mg - mg + F\cos 30° = 0$$

or

$$F_\text{H}\sin\theta = (M + m)g - F\cos 30° \quad (1)$$

Apply $\sum F_x = 0$ to the board:

$$F_\text{H}\cos\theta - F\sin 30° = 0$$

or

$$F_\text{H}\cos\theta = F\sin 30° \quad (2)$$

Divide the first of these equations by the second to obtain:

$$\frac{F_\text{H}\sin\theta}{F_\text{H}\cos\theta} = \frac{(M + m)g - F\cos 30°}{F\sin 30°}$$

Solve for θ:

$$\theta = \tan^{-1}\left[\frac{(M + m)g - F\cos 30°}{F\sin 30°}\right]$$

Substitute numerical values and evaluate θ:

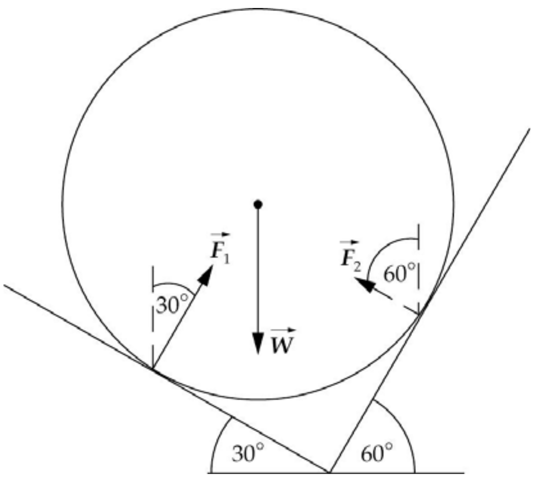
$$\theta = \tan^{-1}\left[\frac{(65\,\text{kg})(9.81\,\text{m/s}^2) - (157\,\text{N})\cos 30°}{(157\,\text{N})\sin 30°}\right] = 81.1°$$

Substitute numerical values in equation (2) and evaluate F_H:

$$F_H = \frac{(157\,\text{N})\sin 30°}{\cos 81.1°} = \boxed{507\,\text{N}}$$

***27** •

Picture the Problem The planes are frictionless; therefore, the force exerted by each plane must be perpendicular to that plane. Let $\vec{F}_1$ be the force exerted by the 30° plane, and let $\vec{F}_2$ be the force exerted by the 60° plane. Choose a coordinate system in which the positive x direction is to the right and the positive y direction is upward. Because the cylinder is in equilibrium, we can use the conditions for translational equilibrium to find the magnitudes of $\vec{F}_1$ and $\vec{F}_2$.



Apply $\sum F_x = 0$ to the cylinder:

$$F_1 \sin 30° - F_2 \sin 60° = 0 \qquad (1)$$

Apply $\sum F_y = 0$ to the cylinder:

$$F_1 \cos 30° + F_2 \cos 60° - W = 0 \qquad (2)$$

Solve equation (1) for F_1:

$$F_1 = \sqrt{3}F_2 \qquad (3)$$

Substitute in equation (2) to obtain:

$$\sqrt{3}F_2 \cos 30° + F_2 \cos 60° - W = 0$$

Solve for F_2:

$$\left(\sqrt{3}\cos 30° + \cos 60°\right)F_2 = W$$

or

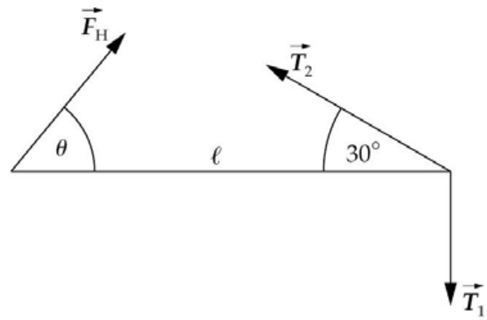
$$F_2 = \frac{W}{\sqrt{3}\cos 30° + \cos 60°} = \boxed{\tfrac{1}{2}W}$$

Substitute in equation (3):

$$F_1 = \sqrt{3}\left(\tfrac{1}{2}W\right) = \boxed{\tfrac{\sqrt{3}}{2}W}$$

28 ••

Picture the Problem The force diagram shows the forces $\vec{F}_H$, $\vec{T}_2$, and $\vec{T}_1$ acting on the strut. Choose a coordinate system in which the positive x direction is to the right and the positive y direction is upward. Because the strut is in equilibrium, we can apply the conditions for translational and rotational equilibrium to it.



(*a*) The forces acting on the strut are the tensions $\vec{T}_1$ and $\vec{T}_2$ and $\vec{F}_H$, the force exerted on the strut by the hinge.

(*b*) Apply $\sum \vec{\tau} = 0$ about an axis through the hinge:

$$T_2 \ell \sin 30° - T_1 \ell = 0$$

Solve for T_1:

$$T_{2v} = T_2 \sin 30° = T_1$$

or, because T_1 = 80 N,

$$T_{2v} = \boxed{80\text{ N}}$$

(*c*) Apply $\sum F_x = 0$ to the beam:

$$F_H \cos\theta - T_2 \cos 30° = 0$$

or

$$F_H \cos\theta = T_2 \cos 30° \quad (1)$$

Apply $\sum F_y = 0$ to the beam:

$$F_H \sin\theta + T_2 \sin 30° - T_1 = 0$$

or

$$F_H \sin\theta = T_1 - T_2 \sin 30° = 80\text{ N} - T_2 \sin 30° \quad (2)$$

Divide equation (2) by equation (1) to obtain:

$$\tan\theta = \frac{80\text{ N} - T_2 \sin 30°}{T_2 \cos 30°}$$

Solve for θ:

$$\theta = \tan^{-1}\left[\frac{80\text{ N} - T_2 \sin 30°}{T_2 \cos 30°}\right]$$

Express T_2 in terms of T_{2v}:

$$T_2 = \frac{T_{2v}}{\sin 30°} = \frac{80\text{ N}}{\sin 30°} = 160\text{ N}$$

Evaluate θ:

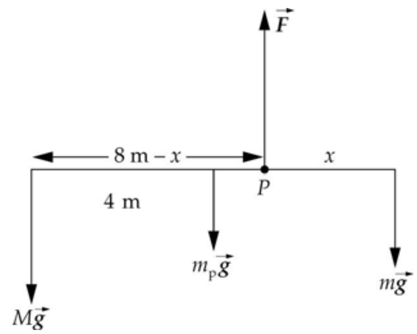
$$\theta = \tan^{-1}\left[\frac{80\,\text{N} - (160\,\text{N})\sin 30°}{(160\,\text{N})\cos 30°}\right] = 0°$$

Substitute numerical values in equation (1) and evaluate F_H:

$$F_H = \frac{(160\,\text{N})\cos 30°}{\cos 0°} = \boxed{139\,\text{N}}$$ to the right.

29 ••

Picture the Problem The force diagram shows the weight of the pirate, $M\vec{g}$, the weight of the victim, $m\vec{g}$, and the force the deck exerts at the edge of the ship, $\vec{F}$ acting at the fulcrum P. The diagram also shows, for part (b), the weight of the plank acting through the plank's center of gravity.



(a) Apply $\sum\vec{\tau} = 0$ at the pivot point P:

$$Mg(8\,\text{m} - x) - mgx = 0$$

or

$$M(8\,\text{m} - x) - mx = 0$$

Solve for x:

$$x = \frac{8M}{M+m} = \frac{8(105\,\text{kg})}{105\,\text{kg} + 63\,\text{kg}} = \boxed{5.00\,\text{m}}$$

(b) Apply $\sum\vec{\tau} = 0$ about an axis through the pivot point P:

$$Mg(8\,\text{m} - x) + m_p g(4\,\text{m} - x) - mgx = 0$$

or

$$M(8\,\text{m} - x) + m_p(4\,\text{m} - x) - mx = 0$$

Solve for x:

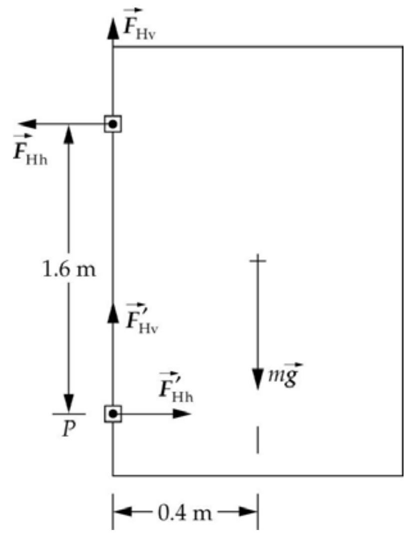
$$x = \frac{8M + 4m_p}{M + m + m_p}$$

Substitute numerical values and evaluate x:

$$x = \frac{8(105\,\text{kg}) + 4(25\,\text{kg})}{105\,\text{kg} + 63\,\text{kg} + 25\,\text{kg}} = \boxed{4.87\,\text{m}}$$

30 ••

Picture the Problem The drawing shows the door and its two supports. The center of gravity of the door is 0.8 m above (and below) the hinge, and 0.4 m from the hinges horizontally. Choose a coordinate system in which the positive x direction is to the right and the positive y direction is upward. Denote the horizontal and vertical components of the hinge force by F_{Hh} and F_{Hv}. Because the door is in equilibrium, we can use the conditions for translational and rotational equilibrium to determine the horizontal forces exerted by the hinges.



Apply $\sum \vec{\tau} = 0$ about an axis through the lower hinge:

$$F_{Hh}(1.6\,\text{m}) - mg(0.4\,\text{m}) = 0$$

Solve for F_{Hh}:

$$F_{Hh} = \frac{mg(0.4\,\text{m})}{1.6\,\text{m}}$$

Substitute numerical values and evaluate F_{Hh}:

$$F_{Hh} = \frac{(18\,\text{kg})(9.81\,\text{m/s}^2)(0.4\,\text{m})}{1.6\,\text{m}} = \boxed{44.1\,\text{N}}$$

Apply $\sum F_x = 0$ to the door and solve for F'_{Hh}:

$$F'_{Hh} - F_{Hh} = 0$$

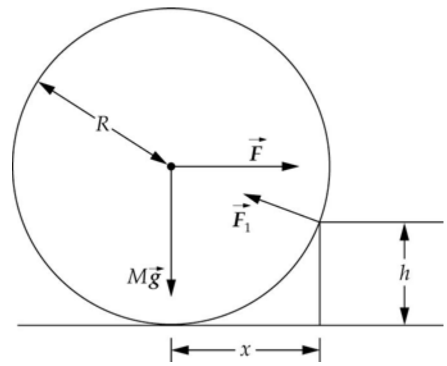
and

$$F'_{Hh} = \boxed{44.1\,\text{N}}$$

Note that the upper hinge pulls on the door and the lower hinge pushes on it.

31 ••

Picture the Problem The figure shows the wheel on the verge of rolling over the edge of the step. Note that, under this condition, the normal force the floor exerts on the wheel is zero. Choose the coordinate system shown in the figure and apply the conditions for translational equilibrium and the result for F from Example 12-4 to the wheel.



Apply $\sum \vec{F} = 0$ to the wheel:

$$\sum F_x = F - F_{1x} = 0$$

and

$$\sum F_y = F_{1y} - Mg = 0$$

Write $\vec{F}_1$ in vector form:

$$\vec{F}_1 = -F_{1x}\hat{\boldsymbol{i}} + F_{1y}\hat{\boldsymbol{j}} = -F\hat{\boldsymbol{i}} + Mg\hat{\boldsymbol{j}}$$

From Example 12-4 we have:

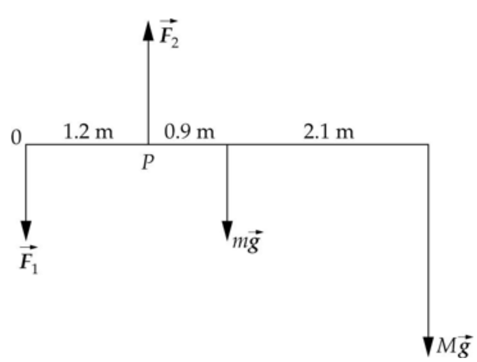
$$F = \frac{Mg\sqrt{h(2R-h)}}{R-h}$$

Substitute to obtain:

$$\vec{F}_1 = -\frac{Mg\sqrt{h(2R-h)}}{R-h}\hat{\boldsymbol{i}} + Mg\hat{\boldsymbol{j}} = \boxed{\frac{Mg\sqrt{h(2R-h)}}{h-R}\hat{\boldsymbol{i}} + Mg\hat{\boldsymbol{j}}}$$

32 ••

Picture the Problem The diagram shows the forces $\vec{F}_1$ and $\vec{F}_2$ acting at the supports, the weight of the board $m\vec{g}$, acting at its center of gravity, and the weight of the diver $M\vec{g}$ acting at the end of the diving board. Because the board is in equilibrium, we can apply the condition for rotational equilibrium to find the forces at the supports.



Apply $\sum \vec{\tau} = 0$ about an axis through the left support:

$$(1.2\,\text{m})F_2 - (2.1\,\text{m})mg - (4.2\,\text{m})Mg = 0$$

Solve for F_2:

$$F_2 = \frac{(2.1\,\text{m})m + (4.2\,\text{m})M}{(1.2\,\text{m})}g$$

Substitute numerical values and evaluate F_2:

$$F_2 = \frac{(2.1\,\text{m})(30\,\text{kg}) + (4.2\,\text{m})(70\,\text{kg})}{(1.2\,\text{m})}(9.81\,\text{m/s}^2) = \boxed{2.92\,\text{kN, compression}}$$

Apply $\sum \vec{\tau} = 0$ about an axis through the right support:

$$(1.2\,\text{m})F_1 - (0.9\,\text{m})mg - (3\,\text{m})Mg = 0$$

Solve for F_1:

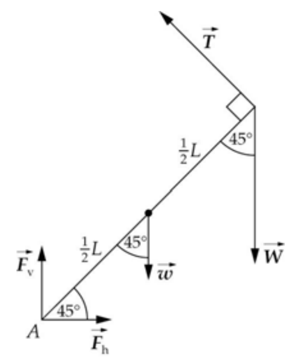
$$F_1 = \frac{(0.9\,\text{m})m + (3\,\text{m})M}{(1.2\,\text{m})}g$$

Substitute numerical values and evaluate F_1:

$$F_1 = \frac{(0.9\,\text{m})(30\,\text{kg}) + (3\,\text{m})(70\,\text{kg})}{(1.2\,\text{m})}(9.81\,\text{m/s}^2) = \boxed{1.94\,\text{kN, tension}}$$

33 ••

Picture the Problem Let T be the tension in the line attached to the wall and L be the length of the strut. The figure includes w, the weight of the strut, for part (b). Because the strut is in equilibrium, we can use the conditions for both rotational and translational equilibrium to find the force exerted on the strut by the hinge.



(a) Express the force exerted on the strut at the hinge:

$$\vec{F} = F_h\hat{i} + F_v\hat{j} \qquad (1)$$

Ignoring the weight of the strut, apply $\sum \vec{\tau} = 0$ at the hinge:

$$LT - (L\cos 45°)W = 0$$

Solve for the tension in the line:

$$T = W\cos 45° = (60\,\text{N})\cos 45° = 42.43\,\text{N}$$

Apply $\sum \vec{F} = 0$ to the strut:

$$\sum F_x = F_h - T\cos 45° = 0$$

and

$$\sum F_y = F_\text{v} + T\cos 45° - Mg = 0$$

Solve for F_h:

$$T_\text{h} = T\cos 45° = (42.43\,\text{N})\cos 45°$$
$$= 30.0\,\text{N}$$

Solve for F_v:

$$F_\text{v} = Mg - T\cos 45°$$
$$= 60\,\text{N} - (42.43\,\text{N})\cos 45°$$
$$= 30.0\,\text{N}$$

Substitute in equation (1) to obtain:

$$\vec{F} = \boxed{(30.0\,\text{N})\hat{\boldsymbol{i}} + (30.0\,\text{N})\hat{\boldsymbol{j}}}$$

(*b*) Including the weight of the strut, apply $\sum\vec{\tau} = 0$ at the hinge:

$$LT - (L\cos 45°)W - \left(\frac{L}{2}\cos 45\right)w = 0$$

Solve for the tension in the line:

$$T = (\cos 45°)W + \left(\frac{1}{2}\cos 45°\right)w$$
$$= (\cos 45°)(60\,\text{N}) + \left(\frac{1}{2}\cos 45°\right)(20\,\text{N})$$
$$= 49.5\,\text{N}$$

Apply $\sum\vec{F} = 0$ to the strut:

$$\sum F_x = F_\text{h} - T\cos 45° = 0$$

and

$$\sum F_y = F_\text{v} + T\cos 45° - W - w = 0$$

Solve for F_h:

$$T_\text{h} = T\cos 45° = (49.5\,\text{N})\cos 45°$$
$$= 35.0\,\text{N}$$

Solve for F_v:

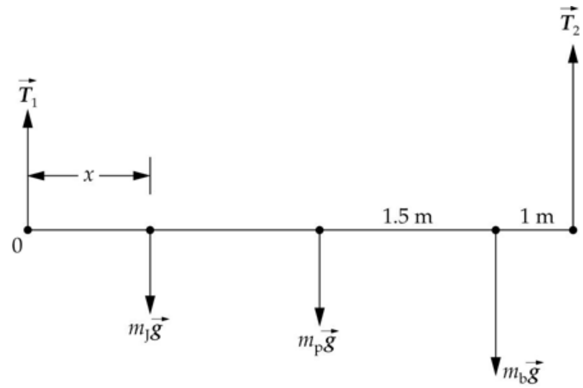
$$F_\text{v} = W + w - T\cos 45°$$
$$= 60\,\text{N} + 20\,\text{N} - (49.5\,\text{N})\cos 45°$$
$$= 45.0\,\text{N}$$

Substitute in equation (1) to obtain:

$$\vec{F} = \boxed{(35.0\,\text{N})\hat{\boldsymbol{i}} + (45.0\,\text{N})\hat{\boldsymbol{j}}}$$

34 ••

Picture the Problem Note that if the 60-kg mass is at the far left end of the plank, T_1 and T_2 are less than 1 kN. Let x be the distance of the 60-kg mass from T_1. Because the plank is in equilibrium, we can apply the condition for rotational equilibrium to relate the distance x to the other distances and forces.



Apply $\sum\vec{\tau} = 0$ about an axis through the left end of the plank:

$$(5\,\text{m})T_2 - (4\,\text{m})m_b g - (2.5\,\text{m})m_p g - m_J g x = 0$$

Solve for x:

$$x = \frac{(5\,\text{m})T_2 - (4\,\text{m})m_b g - (2\,\text{m})m_p g}{m_J g}$$

Substitute numerical values and simplify to obtain:

$$x = \frac{(5\,\text{m})T_2 - 3.63\,\text{kN}\cdot\text{m}}{0.5886\,\text{kN}}$$

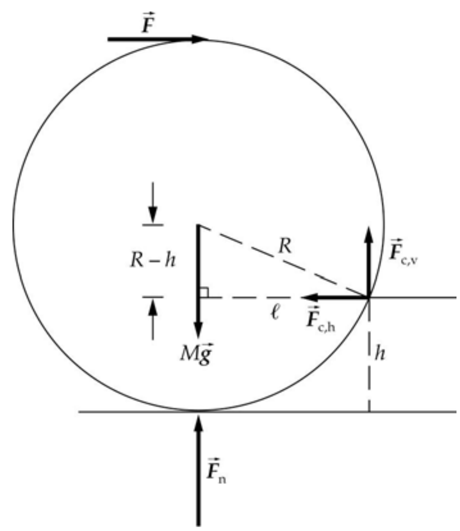
Set T_2 = 1 kN and evaluate x:

$$x = \frac{(5\,\text{m})(1\,\text{kN}) - 3.63\,\text{kN}\cdot\text{m}}{0.5886\,\text{kN}} = 2.33\,\text{m}$$

and $\boxed{\text{Julie is safe for } 0 < x < 2.33\,\text{m.}}$

35 ••

Picture the Problem The figure to the right shows the forces acting on the cylinder. Choose a coordinate system in which the positive *x* direction is to the right and the positive *y* direction is upward. Because the cylinder is in equilibrium, we can apply the conditions for translational and
rotational equilibrium to find F_n and the horizontal and vertical components of the force the corner of the step exerts on the cylinder.



(*a*) Apply $\sum\vec{\tau}=0$ to the cylinder about the step's corner:

$$Mg\ell - F_n\ell - F(2R-h)=0$$

Solve for F_n:

$$F_n = Mg - \frac{F(2R-h)}{\ell}$$

Express ℓ as a function of *R* and *h*:

$$\ell = \sqrt{R^2-(R-h)^2} = \sqrt{2Rh-h^2}$$

$$F_n = Mg - \frac{F(2R-h)}{\sqrt{2Rh-h^2}} = \boxed{Mg - F\sqrt{\frac{2R-h}{h}}}$$

(*b*) Apply $\sum F_x = 0$ to the cylinder:

$$-F_{c,h} + F = 0$$

Solve for $F_{c,h}$:

$$F_{c,h} = \boxed{F}$$

(*c*) Apply $\sum F_y = 0$ to the cylinder:

$$F_n - Mg + F_{c,v} = 0$$

Solve for $F_{c,v}$:

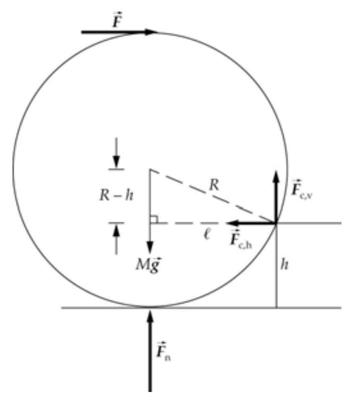
$$F_{c,v} = Mg - F_n$$

Substitute the result from part (*a*):

$$F_{c,v} = Mg - \left\{Mg - F\sqrt{\frac{2R-h}{h}}\right\} = \boxed{F\sqrt{\frac{2R-h}{h}}}$$

36 ••

Picture the Problem The figure to the right shows the forces acting on the cylinder. Because the cylinder is in equilibrium, we can use the condition for rotational equilibrium to express F_n in terms of F. Because, to roll over the step, the cylinder must lift off the floor, we can set $F_n = 0$ in our expression relating F_n and F and solve for F.



Apply $\sum \vec{\tau} = 0$ about the step's corner:

$$Mg\ell - F_n\ell - F(2R-h) = 0$$

Solve for F_n:

$$F_n = Mg - \frac{F(2R-h)}{\ell}$$

Express ℓ as a function of R and h:

$$\ell = \sqrt{R^2 - (R-h)^2} = \sqrt{2Rh - h^2}$$

Substitute to obtain:

$$F_n = Mg - \frac{F(2R-h)}{\sqrt{2Rh-h^2}} = Mg - F\sqrt{\frac{2R-h}{h}}$$

To roll over the step, the cylinder must lift off the floor, i.e., $F_n = 0$:

$$0 = Mg - F\sqrt{\frac{2R-h}{h}}$$

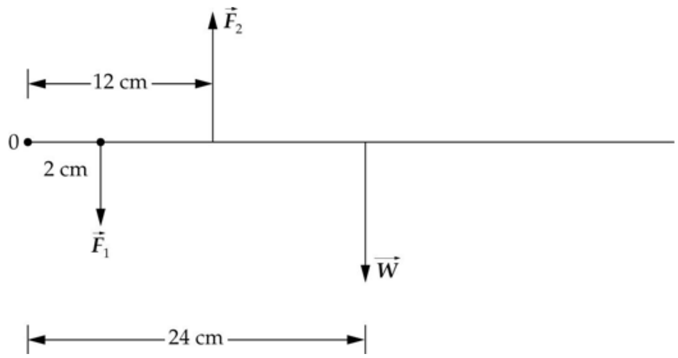
Solve for F:

$$F = \boxed{Mg\sqrt{\frac{h}{2R-h}}}$$

***37** ••

Picture the Problem The diagram shows the forces F_1 and F_2 that the fencer's hand exerts on the epee. We can use a condition for translational equilibrium to find the upward force the fencer must exert on the epee when it is in equilibrium and the definition of torque to determine the total torque exerted. In part (*c*) we can use the conditions for translational and rotational equilibrium to obtain two equations in F_1 and

F_2 that we can solve simultaneously. In part (*d*) we can apply Newton's 2nd law in rotational form and the condition for translational equilibrium to obtain two equations in F_1 and F_2 that, again, we can solve simultaneously.



(*a*) Letting the upward force exerted by the fencer's hand be *F*, apply $\sum F_y = 0$ to the epee to obtain:

$$F - W = 0$$

Solve for and evaluate *F*:

$$F = mg = (0.7\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{6.87\,\text{N}}$$

(*b*) Express the torque due to the weight about the left end of the epee:

$$\tau = \ell w = (0.24\,\text{m})(6.87\,\text{N}) = \boxed{1.65\,\text{N}\cdot\text{m}}$$

(*c*) Apply $\sum F_y = 0$ to the epee to obtain:

$$-F_1 + F_2 - 6.87\,\text{N} = 0 \qquad (1)$$

Apply $\sum \tau_0 = 0$ to obtain:

$$-(0.02\,\text{m})F_1 + (0.12\,\text{m})F_2 - 1.65\,\text{N}\cdot\text{m} = 0$$

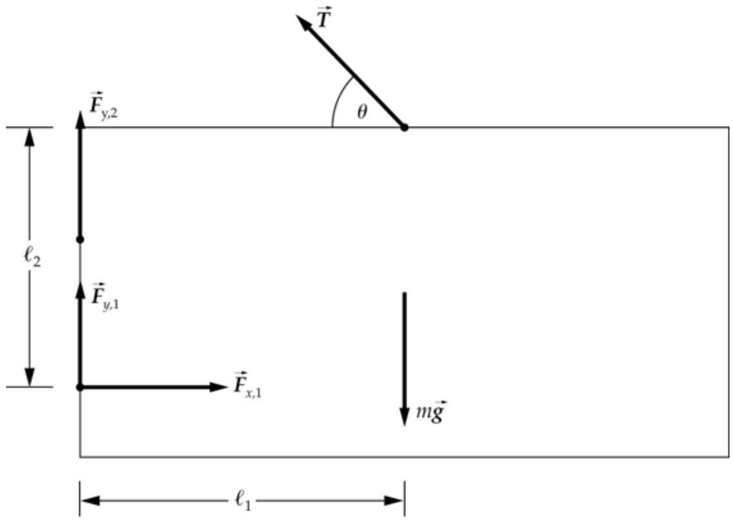
Solve these equations simultaneously to obtain:

$F_1 = \boxed{8.26\,\text{N}}$ and $F_2 = \boxed{15.1\,\text{N}}$.

Note that the force nearest the butt of the epee is directed downward and the force nearest the hand guard is directed upward.

38 ••

Picture the Problem In the force diagram, the forces exerted by the hinges are $\vec{F}_{y,2}$, $\vec{F}_{y,1}$, and $\vec{F}_{x,1}$ where the subscript 1 refers to the lower hinge. Because the gate is in equilibrium, we can apply the conditions for translational and rotational equilibrium to find the tension in the wire and the forces at the hinges.



(*a*) Apply $\sum \vec{\tau} = 0$ about an axis through the lower hinge and perpendicular to the plane of the page:

$$\ell_1 T\sin\theta + \ell_2 T\cos\theta - \ell_1 mg = 0$$

Solve for *T*:

$$T = \frac{\ell_1 mg}{\ell_1 \sin\theta + \ell_2 \cos\theta}$$

Substitute numerical values and evaluate *T*:

$$T = \frac{(1.5\,\text{m})(200\,\text{N})}{(1.5\,\text{m})\sin 45° + (1.5\,\text{m})\cos 45°} = \boxed{141\,\text{N}}$$

(*b*) Apply $\sum F_x = 0$ to the gate:

$$F_{x,1} - T\cos 45° = 0$$

Solve for and evaluate $F_{x,1}$:

$$F_{x,1} = T\cos 45° = (141\,\text{N})\cos 45° = \boxed{99.7\,\text{N}}$$

(*c*) Apply $\sum F_y = 0$ to the gate:

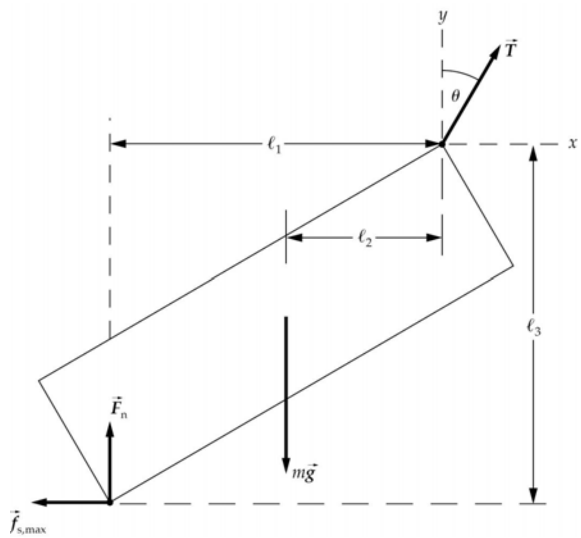
$$F_{y,1} + F_{y,2} + T\sin 45° - mg = 0$$

Because $F_{y,1}$ and $F_{y,2}$ cannot be determined independently, solve for and evaluate their sum:

$$F_{y,1} + F_{y,2} = mg - T\sin 45° = 200\,\text{N} - 99.7\,\text{N} = \boxed{100\,\text{N}}$$

39 •••

Picture the Problem Let T = the tension in the wire; F_n = the normal force of the surface; and $f_{s,max} = \mu_s F_n$ the maximum force of static friction. Letting the point at which the wire is attached to the log be the origin, the center of mass of the log is at (–1.838 m, –0.797 m) and the point of contact with the floor is at (–3.676 m, –1.594 m). Because the log is in equilibrium, we can apply the conditions for translational and rotational equilibrium.



Apply $\sum F_x = 0$ to the log: $T\sin\theta - f_{s,max} = 0$

or

$$T\sin\theta = f_{s,max} = \mu_s F_n \qquad (1)$$

Apply $\sum F_y = 0$ to the log: $T\cos\theta + F_n - mg = 0$

or

$$T\cos\theta = mg - F_n \qquad (2)$$

Divide equation (1) by equation (2) to obtain:

$$\frac{T\sin\theta}{T\cos\theta} = \frac{\mu_s F_n}{mg - F_n}$$

or

$$\theta = \tan^{-1}\frac{\mu_s}{\dfrac{mg}{F_n} - 1} \qquad (3)$$

Apply $\sum \vec{\tau} = 0$ about an axis through the origin:

$$\ell_2 mg - \ell_1 F_n - \ell_3 \mu_s F_n = 0$$

Solve for F_n:

$$F_n = \frac{\ell_2 mg}{\ell_1 + \ell_3 \mu_s}$$

Substitute numerical values and evaluate F_n:

$$F_n = \frac{1.838(100\,\text{kg})(9.81\,\text{m/s}^2)}{3.676 + 1.594(0.6)} = 389\,\text{N}$$

Substitute in equation (3) and evaluate θ:

$$\theta = \tan^{-1}\frac{0.6}{\dfrac{(100\,\text{kg})(9.81\,\text{m/s}^2)}{389\,\text{N}} - 1}$$

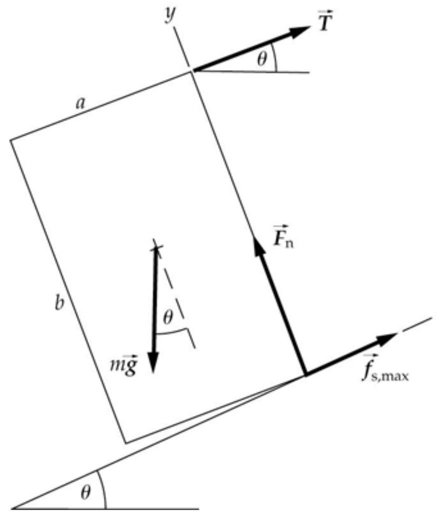
$$= \boxed{21.5^\circ}$$

Substitute numerical values in equation (1) and evaluate T:

$$T = \frac{(0.6)(389\,\text{N})}{\sin 21.5^\circ} = \boxed{636\,\text{N}}$$

40 •••

Picture the Problem Consider what happens just as θ increases beyond θ_{max}. Because the top of the block is fixed by the cord, the block will in fact rotate with only the lower right edge of the block remaining in contact with the plane. It follows that just prior to this slipping, F_n and $f_s = \mu_s F_n$ act at the lower right edge of the block. Choose a coordinate system in which up the incline is the positive x direction and the direction of $\vec{F}_n$ is the positive y direction. Because the block is in equilibrium, we can apply the conditions for translational and rotational equilibrium.



Apply $\sum F_x = 0$ to the block:

$$T + \mu_s F_n - mg\sin\theta = 0 \qquad (1)$$

Apply $\sum F_y = 0$ to the block:

$$F_n - mg\cos\theta = 0 \qquad (2)$$

Apply $\sum \vec{\tau} = 0$ about an axis through the lower right edge of the block:

$$\tfrac{1}{2}a(mg\cos\theta) + \tfrac{1}{2}b(mg\sin\theta) - bT = 0 \qquad (3)$$

Eliminate F_n between equations (1) and (2) and solve for T:

$$T = mg(\sin\theta - \mu_s\cos\theta)$$

Substitute for T in equation (3):

$$\tfrac{1}{2}a(mg\cos\theta)+\tfrac{1}{2}b(mg\sin\theta)-b[mg(\sin\theta-\mu_s\cos\theta)]=0$$

Substitute $4a$ for b:

$$\tfrac{1}{2}a(mg\cos\theta)+\tfrac{1}{2}(4a)(mg\sin\theta)-(4a)[mg(\sin\theta-\mu_s\cos\theta)]=0$$

Simplify to obtain:

$$(1+8\mu_s)\cos\theta-4\sin\theta=0$$

Solve for θ:

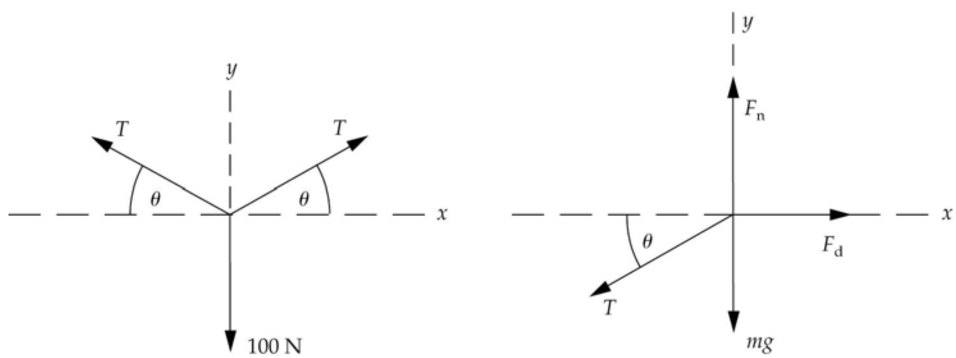
$$\theta=\tan^{-1}\frac{1+8\mu_s}{4}$$

Substitute numerical values and evaluate θ:

$$\theta=\tan^{-1}\frac{1+8(0.8)}{4}=\boxed{61.6°}$$

***41 ••**

Picture the Problem The free-body diagram shown to the left below is for the weight and the diagram to the right is for the boat. Because both are in equilibrium under the influences of the forces acting on them, we can apply a condition for translational equilibrium to find the tension in the chain.



(*a*) Apply $\sum F_x=0$ to the boat:

$$F_d-T\cos\theta=0$$

Solve for T:

$$T=\frac{F_d}{\cos\theta}$$

Apply $\sum F_y=0$ to the weight:

$$2T\sin\theta-100\text{ N}=0 \qquad (1)$$

Substitute for T to obtain:

$$2F_d\tan\theta-100\text{ N}=0$$

Solve for θ:

$$\theta=\tan^{-1}\frac{100\text{ N}}{2F_d}$$

Substitute for F_d and evaluate θ:

$$\theta = \tan^{-1}\frac{100\text{ N}}{2(50\text{ N})} = 45°$$

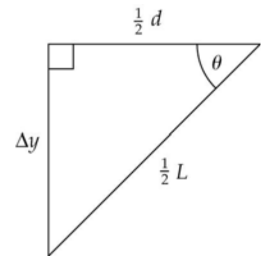
Solve equation (1) for T:

$$T = \frac{100\text{ N}}{2\sin\theta}$$

Substitute for θ and evaluate T:

$$T = \frac{100\text{ N}}{2\sin 45°} = \boxed{70.7\text{ N}}$$

(*b*) Use the diagram to the right to relate the sag Δy in the chain to the angle θ the chain makes with the horizontal:



$$\sin\theta = \frac{\Delta y}{\frac{1}{2}L}$$

where L is the length of the chain.

Solve for Δy:

$$\Delta y = \tfrac{1}{2}L\sin\theta$$

Because the horizontal and vertical forces in the chain are equal, $\theta =$ 45° and:

$$\Delta y = \tfrac{1}{2}(5\text{ m})\sin 45° = \boxed{1.77\text{ m}}$$

(*c*) Relate the distance d of the boat from the dock to the angle θ the chain makes with the horizontal:

$$\cos\theta = \frac{\frac{1}{2}d}{\frac{1}{2}L} = \frac{d}{L}$$

Solve for and evaluate d:

$$d = L\cos\theta = (5\text{ m})\cos 45° = \boxed{3.54\text{ m}}$$

(*d*) Relate the resultant tension in the chain to the vertical component of the tension F_v and the maximum drag force exerted on the boat by the water $F_{d,max}$:

$$F_v^2 + F_{d,max}^2 = (500\text{ N})^2$$

Solve for $F_{d,max}$:

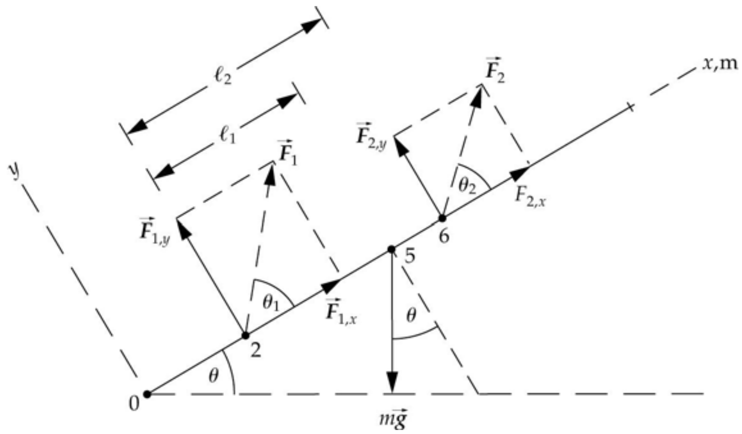
$$F_{d,max} = \sqrt{(500\text{ N})^2 - F_v^2}$$

Because the vertical component of the tension is 50 N:

$$F_{d,max} = \sqrt{(500\text{ N})^2 - (50\text{ N})^2} = \boxed{497\text{ N}}$$

42 ••

Picture the Problem Choose a coordinate system in which the positive x axis is along the rod and the positive y direction is normal to the rod. The rod and the forces acting on it are shown in the free-body diagram. The forces acting at the supports are denoted by the numerals 1 and 2. The resultant forces at the supports are shown as dashed lines. We'll assume that the rod is on the verge of sliding. Because the *x* components of the forces at the supports are friction forces, they are proportional to the normal, i.e., *y*, components of the forces at the supports. Because the rod is in equilibrium, we can apply the conditions for translational and rotational equilibrium.



Apply $\sum\vec{\tau}=0$ about an axis through the support at x = 2 m:

$$\ell_2 F_{2,y}-\ell_1 mg\cos\theta=0$$

Solve for $F_{2,y}$:

$$F_{2,y}=\frac{\ell_1 mg\cos\theta}{\ell_2}$$

Substitute numerical values and evaluate $F_{2,y}$:

$$F_{2,y}=\frac{(3\,\text{m})(20\,\text{kg})(9.81\,\text{m/s}^2)\cos 30°}{4\,\text{m}}=127.4\,\text{N}$$

Apply $\sum\vec{\tau}=0$ about an axis through the support at x = 6 m:

$$(\ell_2-\ell_1)mg\cos\theta-\ell_2 F_{1,y}=0$$

Solve for $F_{1,y}$:

$$F_{1,y}=\frac{(\ell_2-\ell_1)mg\cos\theta}{\ell_2}$$

Substitute numerical values and evaluate $F_{1,y}$:

$$F_{1,y}=\frac{(4\,\text{m}-3\,\text{m})(20\,\text{kg})(9.81\,\text{m/s}^2)}{4\,\text{m}}\times\cos 30°=42.48\,\text{N}$$

Apply $\sum F_x = 0$ to the rail: $F_{1,x} + F_{2,x} - mg\sin 30° = 0$ (1)

Assuming that the rod is on the verge of sliding and that the coefficient of static friction is the same for both supports:

$$F_{1,\mathrm{x}} = \mu_{\mathrm{s}} F_{1,y}$$
and
$$F_{2,\mathrm{x}} = \mu_{\mathrm{s}} F_{2,y}$$

Divide the first of these equations by the second and evaluate this ratio to obtain:

$$\frac{F_{1,x}}{F_{2,x}} = \frac{F_{1,y}}{F_{2,y}} = \frac{42.48\,\mathrm{N}}{127.4\,\mathrm{N}} = \frac{1}{3}$$

Solve for $F_{2,x}$:

$$F_{2,x} = 3F_{1,x}$$

Substitute in equation (1):

$$F_{1,x} + 3F_{1,x} - mg\sin\theta = 0$$

Solve for $F_{1,x}$:

$$F_{1,x} = \tfrac{1}{4} mg\sin\theta$$

Substitute numerical values and evaluate $F_{1,x}$:

$$F_{1,x} = \tfrac{1}{4}(20\,\mathrm{kg})(9.81\,\mathrm{m/s^2})\sin 30° = 24.53\,\mathrm{N}$$

Evaluate $F_{2,x}$:

$$F_{2,x} = 3(24.53\,\mathrm{N}) = 73.58\,\mathrm{N}$$

Find the angle θ_1 the force at support 1 (x = 2 m) makes with the rod:

$$\theta_1 = \tan^{-1}\frac{F_{1,y}}{F_{1,x}} = \tan^{-1}\frac{42.48\,\mathrm{N}}{24.53\,\mathrm{N}} = \boxed{60.0°}$$

Find the angle θ_2 the force at support 2 makes with the rod:

$$\theta_2 = \tan^{-1}\frac{F_{2,y}}{F_{2,x}} = \tan^{-1}\frac{127.4\,\mathrm{N}}{73.58\,\mathrm{N}} = \boxed{60.0°}$$

Find the magnitude of $\vec{F}_1$:

$$F_1 = \sqrt{F_{1,x}^2 + F_{1,y}^2} = \sqrt{(24.53\,\mathrm{N})^2 + (42.48\,\mathrm{N})^2} = \boxed{49.1\,\mathrm{N}}$$

Find the magnitude of $\vec{F}_2$:

$$F_2 = \sqrt{F_{2,x}^2 + F_{2,y}^2}$$
$$= \sqrt{(73.58\,\text{N})^2 + (127.4\,\text{N})^2}$$
$$= \boxed{147\,\text{N}}$$

43 •

Picture the Problem The forces shown in the figure constitute a couple and will cause the plate to experience a counterclockwise angular acceleration. We can find this net torque by expressing the torque about either of the corners of the plate.

Sum the torques about an axis through the upper left corner of the plate to obtain:

$$\tau_{\text{net}} = b[(80\,\text{N})\cos 30°] - a[(80\,\text{N})\sin 30°]$$
$$= \boxed{(69.3\,\text{N})b - (40.0\,\text{N})a}$$

44 •

Picture the Problem We can use the condition for translational equilibrium and the definition of a couple to show that the force of static friction exerted by the surface and the applied force constitute a couple. We can use the definition of torque to find the torque exerted by the couple. We can use our result from (*b*) to find the effective point of application of the normal force when $F = Mg/3$ and the condition for rotational equilibrium to find the greatest magnitude of $\vec{F}$ for which the cube will not tip.

(*a*) Apply $\sum \vec{F}_x = 0$ to the stationary cube:

$$\vec{F} + \vec{f}_s = 0$$

$$\boxed{\therefore \vec{F} = -\vec{f}_s \text{ and this pair of equal, parallel, and oppositely directed forces constitute a couple.}}$$

The torque of the couple is:

$$\tau_{\text{couple}} = \boxed{Fa}$$

(*b*) Let x = the distance from the point of application of F_n to the center of the cube. Now, $F_n = Mg$, so applying $\sum \vec{\tau} = 0$ to the cube yields:

$$Mgx - Fa = 0 \qquad (1)$$

or

$$x = \frac{Fa}{Mg}$$

Substitute for $F = Mg/3$ to obtain:

$$x = \frac{\frac{Mg}{3}a}{Mg} = \boxed{\frac{a}{3}}$$

(*c*) Solve equation (1) for F:

$$F = \frac{Mgx}{a}$$

Noting that $x_{max} = a/2$, substitute to express the condition that the cube will tip:

$$F > \frac{Mgx_{max}}{a} = \frac{Mg\frac{a}{2}}{a} = \boxed{\frac{Mg}{2}}$$

45 ••

Picture the Problem We can find the perpendicular distance between the lines of action of the two forces by following the outline given in the problem statement.

Express the vertical components of the forces:

$$F\cos 30° = \frac{\sqrt{3}}{2}F$$

Express the horizontal components of the forces:

$$F\sin 30° = \frac{F}{2}$$

Express the net torque acting on the plate:

$$\tau_{net} = \frac{\sqrt{3}}{2}Fb - \frac{1}{2}Fa = \frac{1}{2}F\left(\sqrt{3}b - a\right)$$

Letting D be the moment arm of the couple, express the net torque acting on the plate:

$$\tau_{net} = FD$$

Equate these two expressions for τ_{net}:

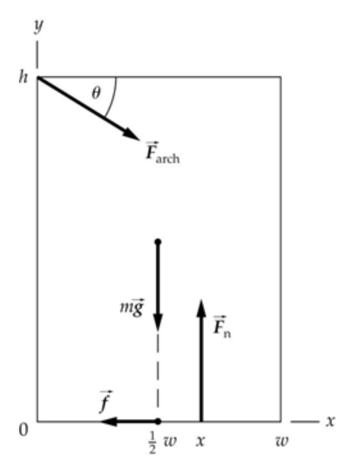
$$FD = \tfrac{1}{2}F\left(\sqrt{3}b - a\right)$$

Solve for D:

$$D = \boxed{\tfrac{1}{2}\left(\sqrt{3}b - a\right)}$$

***46 ••**

Picture the Problem Choose the coordinate system shown in the diagram and let x be the coordinate of the thrust point. The diagram to the right shows the forces acting on the wall. The normal force must balance out the weight of the wall and the vertical component of the thrust from the arch and the frictional force must balance out the horizontal component of the thrust. We can apply the conditions for translational equilibrium to find f and F_n and the condition for rotational equilibrium to find the distance x from the origin of our coordinate system at which F_n acts.



(*a*) Apply the conditions for translational equilibrium to the wall to obtain:

$$\sum F_x = -f + F_{\text{arch}}\cos\theta = 0 \qquad (1)$$

and

$$\sum F_y = F_{\text{n}} - mg - F_{\text{arch}}\sin\theta = 0 \qquad (2)$$

Solve equation (1) for and evaluate *f*:

$$f = F_{\text{arch}}\cos\theta = \left(2\times10^4\ \text{N}\right)\cos 30° = \boxed{17.3\,\text{kN}}$$

Solve equation (2) for F_{n}:

$$F_{\text{n}} = mg + F_{\text{arch}}\sin\theta$$

Substitute numerical values and evaluate F_{n}:

$$F_{\text{n}} = \left(3\times10^4\ \text{kg}\right)\left(9.81\,\text{m/s}^2\right) + \left(2\times10^4\ \text{N}\right)\sin 30° = \boxed{304\,\text{kN}}$$

Apply $\sum \tau_{z\,\text{axis}} = 0$ to the to the wall:

$$xF_{\text{n}} - \tfrac{1}{2}wmg - hF_{\text{arch}}\cos\theta = 0$$

Solve for *x*:

$$x = \frac{\tfrac{1}{2}wmg + hF_{\text{arch}}\cos\theta}{F_{\text{n}}}$$

Substitute numerical values and evaluate *x*:

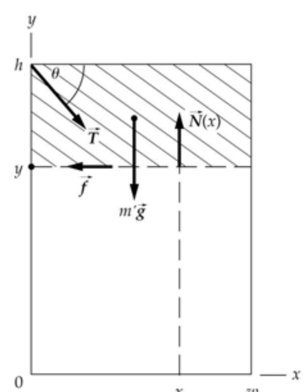
$$x = \frac{\tfrac{1}{2}(1.25\,\text{m})\left(3\times10^4\ \text{kg}\right)\left(9.81\,\text{m/s}^2\right) + (10\,\text{m})\left(2\times10^4\ \text{N}\right)\cos 30°}{304\,\text{kN}} = \boxed{0.570\,\text{m}}$$

(*b*)

If there were no thrust on the side of the wall, the normal force would act through the center of mass, so making the weight larger compared to the thrust must move the point of action of the normal force closer to the center.

47 ••

Picture the Problem Let *h* be the height of the structure, *T* be the thrust, θ the angle from the horizontal of the thrust, $m'g$ the weight of the wall above height *y*, *N*(*x*) the normal force, *f* the friction force the lower part of the wall exerts on the upper part, and *w* the width of the structure. We can apply the conditions for translational and rotational equilibrium to the portion of the wall above the point at which the thrust is applied to obtain two equations that we can solve simultaneously for *x*.



Apply $\sum F_y = 0$ to that fraction of the wall above height *y*:

$$N(x) - T\sin\theta - m'g = 0$$

Assuming the wall is of uniform density, express $m'g$ in terms of *mg*:

$$\frac{m'g}{h-y} = \frac{mg}{h}$$

and

$$m'g = mg\left(1 - \frac{y}{h}\right)$$

Substitute to obtain:

$$N(x) - T\sin\theta - mg\left(1 - \frac{y}{h}\right) = 0$$

Solve for *N*(*x*):

$$N(x) = T\sin\theta + mg\left(1 - \frac{y}{h}\right)$$

Apply $\sum \vec{\tau} = 0$ about an axis through (0,*y*) and perpendicular to the *xy* plane to obtain:

$$xN(x) - (h-y)T\cos\theta - \tfrac{1}{2}mgw\left(1 - \frac{y}{h}\right) = 0$$

Solve for *x* to obtain:

$$x = \frac{\tfrac{1}{2}mgw + hT\cos\theta}{N(x)}\left(1 - \frac{y}{h}\right)$$

Substitute for *N*(*x*) to obtain:

$$x = \frac{\left(\tfrac{1}{2}mgw + hT\cos\theta\right)\left(1 - \frac{y}{h}\right)}{T\sin\theta + mg\left(1 - \frac{y}{h}\right)}$$

Substitute numerical values and simplify to obtain:

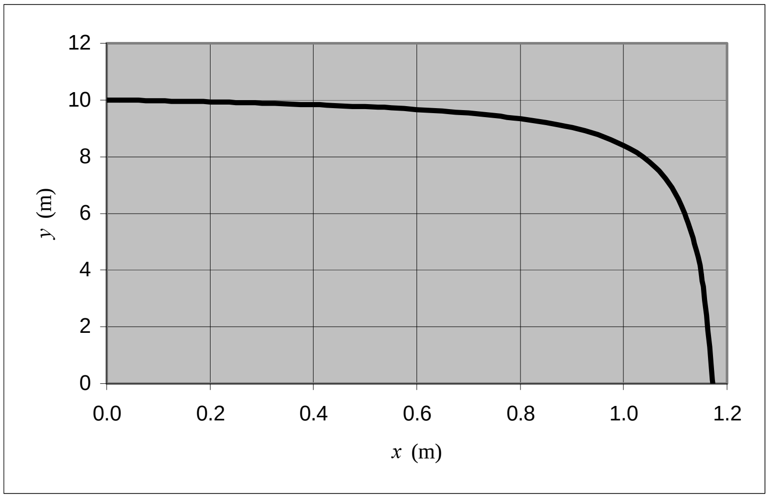
$$x = \frac{\left[\tfrac{1}{2}\left(3\times10^4\text{ kg}\right)\left(9.81\text{m/s}^2\right)\left(1.25\text{m}\right) + \left(10\text{m}\right)\left(2\times10^4\text{ N}\right)\cos 30°\right]\left(1 - \frac{y}{10\text{m}}\right)}{\left(2\times10^4\text{ N}\right)\sin 30° + \left(3\times10^4\text{ kg}\right)\left(9.81\text{m/s}^2\right)\left(1 - \frac{y}{10\text{m}}\right)}$$

$$= \frac{35.71\text{m} - 3.571y}{30.43 - \left(2.943\text{m}^{-1}\right)y}$$

Solve for *y*:

$$y = \boxed{\frac{35.71\text{m} - 30.43x}{3.571 - \left(2.943\text{m}^{-1}\right)x}}$$

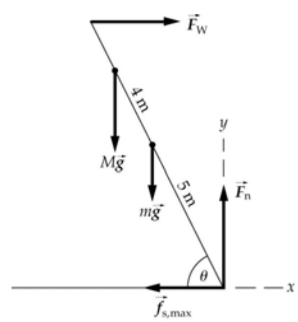
The graph shown below was plotted using a spreadsheet program:



Ladder Problems

***48 ••**

Picture the Problem The ladder and the forces acting on it at the critical moment of slipping are shown in the diagram. Use the coordinate system shown. Because the ladder is in equilibrium, we can apply the conditions for translational and rotational equilibrium.



Using its definition, express μ_s:

$$\mu_s = \frac{f_{s,max}}{F_n} \qquad (1)$$

Apply $\sum \vec{\tau} = 0$ about the bottom of the ladder:

$$[(9\,\text{m})\cos\theta\,]Mg + [(5\,\text{m})\cos\theta]mg - [(10\,\text{m})\sin\theta]F_W = 0$$

Solve for F_W:

$$F_W = \frac{(9\,\text{m})M + (5\,\text{m})m}{(10\,\text{m})\sin\theta} g\cos\theta$$

Find the angle θ:

$$\theta = \cos^{-1}\frac{2.8\,\text{m}}{10\,\text{m}} = 73.74°$$

Evaluate F_W:

$$F_W = \frac{(9\,\text{m})(70\,\text{kg}) + (5\,\text{m})(22\,\text{kg})}{(10\,\text{m})\sin 73.74°} \times (9.81\,\text{m/s}^2)\cos 73.74° = 211.7\,\text{N}$$

Apply $\sum F_x = 0$ to the ladder and solve for $f_{s,max}$:

$$F_W - f_{s,max} = 0$$

and

$$f_{s,max} = F_W = 211.7\,\text{N}$$

Apply $\sum F_y = 0$ to the ladder:

$$F_n - Mg - mg = 0$$

Solve for F_n:

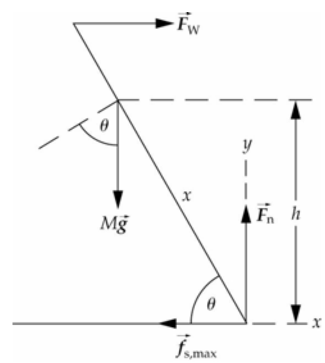
$$F_n = (M + m)g = (70\,\text{kg} + 22\,\text{kg})(9.81\,\text{m/s}^2) = 902.5\,\text{N}$$

Substitute numerical values in equation (1) and evaluate μ_s:

$$\mu_s = \frac{211.7\,\text{N}}{902.5\,\text{N}} = \boxed{0.235}$$

49 ••

Picture the Problem The ladder and the forces acting on it are shown in the diagram. Because the wall is smooth, the force the wall exerts on the ladder must be horizontal. Because the ladder is in equilibrium, we can apply the conditions for translational and rotational equilibrium to it.



Apply $\sum F_y = 0$ to the ladder and solve for F_n:

$$F_n - Mg = 0 \Rightarrow F_n = Mg$$

Apply $\sum F_x = 0$ to the ladder and solve for $f_{s,max}$:

$$F_W - f_{s,max} = 0 \Rightarrow f_{s,max} = F_W$$

Apply $\sum \vec{\tau} = 0$ about the bottom of the ladder:

$$Mgx\cos\theta - F_W L\sin\theta = 0$$

Solve for x:

$$x = \frac{F_W L\sin\theta}{Mg\cos\theta} = \frac{f_{s,max}L}{Mg}\tan\theta$$
$$= \frac{\mu_s F_n L}{Mg}\tan\theta = \mu_s L\tan\theta$$

Referring to the figure, relate x to h and solve for h:

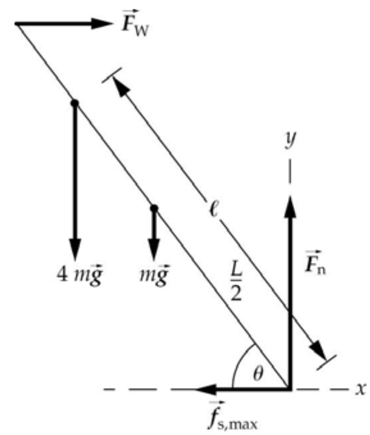
$$\sin\theta = \frac{h}{x}$$

and

$$h = x\sin\theta = \boxed{\mu_s L\tan\theta\sin\theta}$$

50 ••

Picture the Problem The ladder and the forces acting on it are shown in the drawing. Choose a coordinate system in which the positive x direction is to the right and the positive y direction is upward. Because the wall is smooth, the force the wall exerts on the ladder must be horizontal. Because the ladder is in equilibrium, we can apply the conditions for translational and rotational equilibrium.



Apply $\sum F_y = 0$ to the ladder and solve for F_n:

$$F_n - mg - 4mg = 0$$

and

$$F_n = 5mg$$

Apply $\sum F_x = 0$ to the ladder and solve for $f_{s,max}$:

$$F_W - f_{s,max} = 0$$

and

$$f_{s,max} = F_W$$

Apply $\sum \vec{\tau} = 0$ about an axis through the bottom of the ladder:

$$mg\frac{L}{2}\cos\theta + 4mg\ell\cos\theta - F_W L\sin\theta = 0$$

Substitute for F_W and then $f_{s,max}$ and solve for ℓ:

$$\ell = \frac{5\mu_s mgL\sin\theta - \frac{1}{2}mgL\cos\theta}{4mg\cos\theta}$$

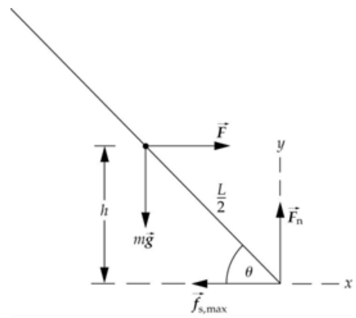
Simplify to obtain:

$$\ell = \left(\frac{5\mu_s}{4}\tan\theta - \frac{1}{8}\right)L = \left(\frac{5(0.45)}{4}\tan 60° - \frac{1}{8}\right)L = \boxed{0.849L}$$

i.e., you can climb about 85% of the way to the top of the ladder.

51 ••

Picture the Problem The ladder and the forces acting on it are shown in the figure. Because the ladder is separating from the wall, the force the wall exerts on the ladder is zero. Because the ladder is in equilibrium, we can apply the conditions for translational and rotational equilibrium.



To find the force required to pull the ladder away from the wall, apply $\sum \vec{\tau} = 0$ about an axis through the bottom of the ladder:

$$mg\frac{L}{2}\cos\theta - \frac{L}{2}F\sin\theta = 0$$

or, because $\frac{L}{2}\cos\theta = \frac{h}{\tan\theta}$,

$$\frac{mgh}{\tan\theta} - \frac{L}{2}F\sin\theta = 0$$

Solve for F:

$$F = \frac{2mgh}{L\tan\theta\sin\theta} \quad (1)$$

Apply $\sum F_x = 0$ to the ladder:

$$F - f_{s,max} = 0 \Rightarrow F = f_{s,max} = \mu_s F_n \quad (2)$$

Apply $\sum F_y = 0$ to the ladder:

$$F_n - mg = 0 \Rightarrow F_n = mg$$

Equate equations (1) and (2) and substitute for F_n to obtain:

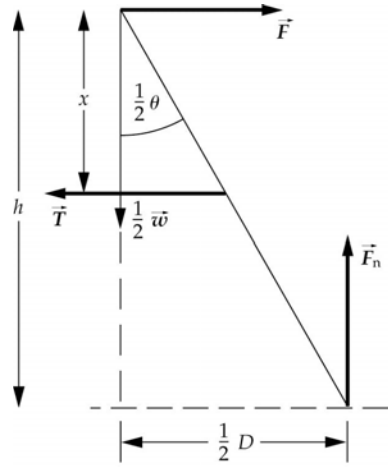
$$\mu_s mg = \frac{2mgh}{L\tan\theta\sin\theta}$$

Solve for μ_s:

$$\mu_s = \boxed{\frac{2h}{L\tan\theta\sin\theta}}$$

52 ••

Picture the Problem Assume that half the man's weight acts on each side of the ladder. The force exerted by the frictionless floor must be vertical. D is the separation between the legs at the bottom and x is the distance of the cross brace from the apex. Because each leg of the ladder is in equilibrium, we can apply the condition for rotational equilibrium the right leg to relate the tension in the cross brace to its distance from the apex.



(*a*) By symmetry, each leg carries half the total weight. So the force on each leg is:

$$\boxed{450\text{ N}}$$

(*b*) Consider one of the ladder's legs and apply $\sum\vec{\tau} = 0$ about the apex:

$$F_n\frac{D}{2} - Tx = 0$$

Solve for T:

$$T = \frac{F_n D}{2x}$$

Using trigonometry, relate h and θ through the tangent function:

$$\tan\tfrac{1}{2}\theta = \frac{D/2}{h}$$

Solve for D to obtain:

$$D = 2h\tan\tfrac{1}{2}\theta$$

Substitute and simplify to obtain:

$$T = \frac{2F_n h\tan\frac{1}{2}\theta}{2x} = \frac{F_n h\tan\frac{1}{2}\theta}{x}$$

Substitute numerical values and evaluate T:

$$T = \frac{F_n h\tan\frac{1}{2}\theta}{x}$$

Apply $\sum F_y = 0$ to the ladder and solve for F_n:

$$F_n - \tfrac{1}{2}w = 0 \text{ and } F_n = \tfrac{1}{2}w$$

Substitute to obtain:

$$T = \frac{wh\tan\frac{1}{2}\theta}{2x} \qquad (1)$$

Substitute numerical values and evaluate T:

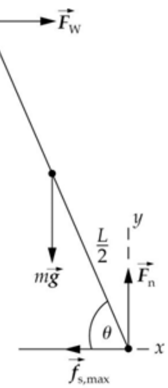
$$T = \frac{(900\,\text{N})(4\,\text{m})\tan 15°}{2(2\,\text{m})} = \boxed{241\,\text{N}}$$

(c) From equation (1) we can see that, if x is increased, i.e., the brace moved lower:

$$\boxed{T \text{ will decrease.}}$$

53 ••

Picture the Problem The figure shows the forces acting on the ladder. Because the wall is frictionless, the force the wall exerts on the ladder is perpendicular to the wall. Because the ladder is on the verge of slipping, the static friction force is $f_{s,max}$. Because the ladder is in equilibrium, we can apply the conditions for translational and rotational equilibrium.



Apply $\sum F_x = 0$ to the ladder:

$$F_W - f_{s,max} = 0 \Rightarrow F_W = f_{s,max} = \mu_s F_n$$

Apply $\sum F_y = 0$ to the ladder:

$$F_n - mg = 0 \Rightarrow F_n = mg$$

Apply $\sum \vec{\tau} = 0$ about an axis through the bottom of the ladder:

$$mg\frac{L}{2}\cos\theta - LF_W \sin\theta = 0$$

Substitute for F_W and F_n and simplify to obtain:

$$\tfrac{1}{2}\cos\theta - \mu_s \sin\theta = 0$$

Solve for and evaluate θ:

$$\theta = \tan^{-1}\frac{1}{2\mu_s} = \tan^{-1}\frac{1}{2(0.3)} = \boxed{59.0°}$$

Stress and Strain

***54** •

Picture the Problem L is the unstretched length of the wire, F is the force acting on it, and A is its cross-sectional area. The stretch in the wire ΔL is related to Young's modulus by $Y = (F/A)/(\Delta L/L)$. We can use Table 12-1 to find the numerical value of Young's modulus for steel.

Find the amount the wire is stretched from Young's modulus:

$$Y = \frac{F/A}{\Delta L/L}$$

Solve for ΔL:

$$\Delta L = \frac{FL}{YA}$$

Substitute for F and A to obtain:

$$\Delta L = \frac{mgL}{Y\pi r^2}$$

Substitute numerical values and evaluate ΔL:

$$\Delta L = \frac{(50\,\text{kg})(9.81\,\text{m/s}^2)(5\,\text{m})}{2\pi\times10^{11}\,\text{N/m}^2(2\times10^{-3}\,\text{m})^2} = \boxed{0.976\,\text{mm}}$$

55 •

Picture the Problem L is the unstretched length of the wire, F is the force acting on it, and A is its cross-sectional area. The stretch in the wire ΔL is related to Young's modulus by $Y = \text{stress/strain} = (F/A)/(\Delta L/L)$.

(*a*) Express the maximum load in terms of the wire's breaking stress:

$$F_{\text{max}} = \text{breaking stress} \times A = \text{breaking stress} \times \pi r^2$$

Substitute numerical values and evaluate F_{max}:

$$F_{\text{max}} = (3\times10^8\,\text{N/m}^2)\pi(0.21\times10^{-3}\,\text{m})^2 = \boxed{41.6\,\text{N}}$$

(*b*) Using the definition of Young's modulus, express the fractional change in length of the copper wire:

$$\Delta L/L = \frac{F/A}{Y} = \frac{1.5\times10^8\,\text{N/m}^2}{1.1\times10^{11}\,\text{N/m}^2} = 1.36\times10^{-3} = \boxed{0.136\%}$$

56 •

Picture the Problem L is the unstretched length of the wire, F is the force acting on it, and A is its cross-sectional area. The stretch in the wire ΔL is related to Young's modulus by $Y = (F/A)/(\Delta L/L)$. We can use Table 12-1 to find the numerical value of Young's modulus for steel.

Find the amount the wire is stretched from Young's modulus:

$$Y = \frac{F/A}{\Delta L/L}$$

Solve for ΔL:

$$\Delta L = \frac{FL}{YA}$$

Substitute for F and A to obtain:

$$\Delta L = \frac{mgL}{Y\pi r^2}$$

Substitute numerical values and evaluate ΔL:

$$\Delta L = \frac{(4\,\text{kg})(9.81\,\text{m/s}^2)(1.2\,\text{m})}{2\pi \times 10^{11}\,\text{N/m}^2\,(0.3\times 10^{-3}\,\text{m})^2} = \boxed{0.833\,\text{mm}}$$

***57** •

Picture the Problem The shear stress, defined as the ratio of the shearing force to the area over which it is applied, is related to the shear strain through the definition of the shear modulus; $M_s = \dfrac{\text{shear stress}}{\text{shear strain}} = \dfrac{F_s/A}{\tan\theta}$.

Using the definition of shear modulus, relate the angle of shear, θ to the shear force and shear modulus:

$$\tan\theta = \frac{F_s}{M_s A}$$

Solve for θ:

$$\theta = \tan^{-1}\frac{F_s}{M_s A}$$

Substitute numerical values and evaluate θ:

$$\theta = \tan^{-1}\frac{25\,\text{N}}{(1.9\times 10^5\,\text{N/m}^2)(15\times 10^{-4}\,\text{m}^2)} = \boxed{5.01°}$$

58 ••

Picture the Problem The stretch in the wire ΔL is related to Young's modulus by $Y = (F/A)/(\Delta L/L)$, where L is the unstretched length of the wire, F is the force acting on it, and A is its cross-sectional area. For a composite wire, the length under stress is the unstressed length plus the sum of the elongations of the components of the wire.

Express the length of the composite wire when it is supporting a mass of 5 kg:

$$L = 3.00\,\text{m} + \Delta L \qquad (1)$$

Express the change in length of the composite wire:

$$\Delta L = \Delta L_{\text{steel}} + \Delta L_{\text{Al}} = \frac{F}{A}\frac{L_{\text{steel}}}{Y_{\text{steel}}} + \frac{F}{A}\frac{L_{\text{Al}}}{Y_{\text{Al}}} = \frac{F}{A}\left(\frac{L_{\text{steel}}}{Y_{\text{steel}}} + \frac{L_{\text{Al}}}{Y_{\text{Al}}}\right)$$

Find the stress in each wire:

$$\frac{F}{A}=\frac{(5\,\text{kg})(9.81\,\text{m/s}^2)}{\pi(0.5\times10^{-3}\,\text{m})^2}=6.245\times10^{7}\ \text{N/m}^2$$

Substitute numerical values and evaluate ΔL:

$$\Delta L=(6.245\times10^{7}\ \text{N/m}^2)\left(\frac{1.5\,\text{m}}{2\times10^{11}\ \text{N/m}^2}+\frac{1.5\,\text{m}}{0.7\times10^{11}\ \text{N/m}^2}\right)=1.81\times10^{-3}\ \text{m}$$

Substitute in equation (1) and evaluate L:

$$L=3.00\,\text{m}+1.81\times10^{-3}\ \text{m}=\boxed{3.0018\,\text{m}}$$

59 ••

Picture the Problem We can use Hooke's law and Young's modulus to show that, if the wire is considered to be a spring, the force constant k is given by $k = AY/L$. By treating the wire as a spring we can show the energy stored in the wire is $U = ½F\Delta L$.

Express the relationship between the stretching force, the stiffness constant, and the elongation of a spring:

$$F=k\Delta L$$

or

$$k=\frac{F}{\Delta L}$$

Using the definition of Young's modulus, express the ratio of the stretching force to the elongation of the wire:

$$\frac{F}{\Delta L}=\frac{AY}{L}\qquad(1)$$

Equate these two expressions for $F/\Delta L$ to obtain:

$$k=\boxed{\frac{AY}{L}}$$

Treating the wire as a spring, express its stored energy:

$$U=\tfrac{1}{2}k(\Delta L)^2=\tfrac{1}{2}\frac{AY}{L}(\Delta L)^2$$

Solve equation (1) for F:

$$F=\frac{AY\Delta L}{L}$$

Substitute in our expression for U to obtain:

$$U=\tfrac{1}{2}\frac{AY\Delta L}{L}\Delta L=\boxed{\tfrac{1}{2}F\Delta L}$$

60 ••

Picture the Problem Let L' represent the stretched and L the unstretched length of the wire. The stretch in the wire ΔL is related to Young's modulus by $Y = (F/A)/(\Delta L/L)$, where F is the force acting on it, and A is its cross-sectional area. In problem 58 we showed that the energy stored in the wire is $U = \frac{1}{2}F\Delta L$, where Y is Young's modulus and ΔL is the amount the wire has stretched.

(*a*) Express the stretched length of the wire:

$$L' = L + \Delta L$$

Using the definition of Young's modulus, express ΔL:

$$\Delta L = \frac{LF}{AY}$$

Substitute and simplify:

$$L' = L + \frac{LF}{AY} = L\left(1 + \frac{F}{AY}\right)$$

Solve for L:

$$L = \frac{L'}{1 + \frac{F}{AY}}$$

Substitute numerical values and evaluate L:

$$L = \frac{0.35\,\text{m}}{1 + \frac{53\,\text{N}}{\pi\left(0.1\times10^{-3}\,\text{m}\right)^2\left(2\times10^{11}\,\text{N/m}^2\right)}} = \boxed{0.347\,\text{m}}$$

(*b*) Using the expression from Problem 59, express the work done in stretching the wire:

$$W = \Delta U = \tfrac{1}{2}F\Delta L = \tfrac{1}{2}(53\,\text{N})(0.35\,\text{m} - 0.347\,\text{m}) = \boxed{0.0795\,\text{J}}$$

***61** ••

Picture the Problem The table to the right summarizes the ratios $\Delta L/F$ for the student's data. Note that this ratio is constant, to three significant figures, for loads less than or equal to 200 g. We can use this ratio to calculate Young's modulus for the rubber strip.

Load (g)	F (N)	ΔL (m)	$\Delta L/F$ (m/N
100	0.981	0.006	6.12×10^{-3}
200	1.962	0.012	6.12×10^{-3}
300	2.943	0.019	6.46×10^{-3}
400	3.924	0.028	7.14×10^{-3}
500	4.905	0.05	10.2×10^{-3}

(*a*) Referring to the table, we see that for loads ≤ 200 g:

$$\frac{\Delta L}{F}=6.12\times10^{-3}\ \text{m/N}$$

Use the definition of Young's modulus to express *Y*:

$$Y=\frac{FL}{A\Delta L}=\frac{L}{A\frac{\Delta L}{F}}$$

Substitute numerical values and evaluate *Y*:

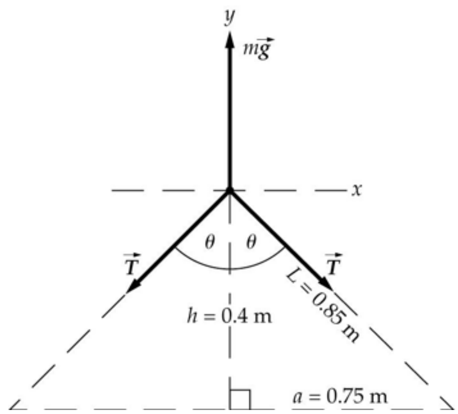
$$Y=\frac{5\times10^{-2}\ \text{m}}{\left(3\times10^{-3}\ \text{m}\right)\left(1.5\times10^{-3}\ \text{m}\right)\left(6.12\times10^{-3}\ \text{m/N}\right)}=\boxed{1.82\times10^{6}\ \text{N/m}^2}$$

(*b*) Interpolate to determine the stretch when the load is 150 g, and use the expression from Problem 58, to express the energy stored in the strip:

$$U=\tfrac{1}{2}F\Delta L$$
$$=\tfrac{1}{2}(0.15\,\text{kg})\left(9.81\,\text{m/s}^2\right)\left(9\times10^{-3}\ \text{m}\right)$$
$$=\boxed{6.62\,\text{mJ}}$$

62 ••

Picture the Problem The figure shows the forces acting on the wire where it passes over the nail. *m* represents the mass of the mirror and *T* is the tension in the supporting wires. The figure also shows the geometry of the right triangle defined by the support wires and the top of the mirror frame. The distance *a* is fixed by the geometry while *h* and *L* will change as the mirror is suspended from the nail.



Express the distance between the nail and the top of the frame when the wire is under tension:

$$h'=h+\Delta h$$
$$=0.4\,\text{m}+\Delta h \qquad (1)$$

Apply $\sum F_y=0$ to the wire where it passes over the supporting nail:

$$mg-2T\cos\theta=0$$

Solve for the tension in the wire:

$$T=\frac{mg}{2\cos\theta}$$

Substitute numerical values and evaluate T:

$$T = \frac{(2.4\,\text{kg})(9.81\,\text{m/s}^2)}{2\left(\dfrac{0.4\,\text{m}}{0.85\,\text{m}}\right)} = 25.0\,\text{N}$$

Using its definition, find the stress in the wire:

$$\text{stress} = \frac{T}{A} = \frac{25.0\,\text{N}}{\pi(0.1\times10^{-3}\,\text{m})^2} = 7.96\times10^{8}\ \text{N/m}^2$$

Using the definition of Young's modulus, find the strain in the hypotenuse of the right triangle shown in the figure:

$$\text{strain} = \frac{\Delta L}{L} = \frac{\text{stress}}{Y} = \frac{7.96\times10^{8}\ \text{N/m}^2}{2\times10^{11}\ \text{N/m}^2} = 3.98\times10^{-3}$$

Using the Pythagorean theorem, express the relationship between the sides of the right triangle in the figure:

$$a^2 + h^2 = L^2$$

Express the differential of this equation:

$$2a\Delta a + 2h\Delta h = 2L\Delta L$$

or, because $\Delta a = 0$,

$$h\Delta h = L\Delta L$$

Solve for and evaluate Δh:

$$\Delta h = \frac{L\Delta L}{h} = \frac{L^2}{h}\cdot\frac{\Delta L}{L}$$

Substitute numerical values and evaluate Δh:

$$\Delta h = \frac{(0.85\,\text{m})^2}{0.4\,\text{m}}(3.98\times10^{-3}) = 7.19\,\text{mm}$$

Substitute in equation (1) to obtain:

$$h' = 0.4\,\text{m} + 7.19\,\text{mm} = \boxed{40.72\,\text{cm}}$$

63 ••

Picture the Problem Let the numeral 1 denote the aluminum wire and the numeral 2 the steel wire. Because their initial lengths and amount they stretch are the same, we can use the definition of Young's modulus to express the change in the lengths of each wire and then equate these expressions to obtain an equation solvable for the ratio M_1/M_2.

Using the definition of Young's modulus, express the change in

$$\Delta L_1 = \frac{M_1 g L_1}{A_1 Y_{\text{Al}}}$$

length of the aluminum wire:

Using the definition of Young's modulus, express the change in length of the steel wire:

$$\Delta L_2 = \frac{M_2 g L_2}{A_2 Y_{\text{steel}}}$$

Because the two wires stretch by the same amount, equate ΔL_1 and ΔL_2 and simplify:

$$\frac{M_1}{A_1 Y_{\text{Al}}} = \frac{M_2}{A_2 Y_{\text{steel}}}$$

Solve for the ratio M_1/M_2:

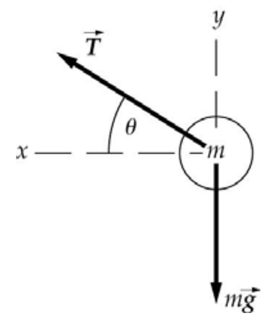
$$\frac{M_1}{M_2} = \frac{A_1 Y_{\text{Al}}}{A_2 Y_{\text{steel}}}$$

Substitute numerical values and evaluate M_1/M_2:

$$\frac{M_1}{M_2} = \frac{\frac{\pi}{4}(0.7\,\text{mm})^2(0.7\times10^{11}\ \text{N/m}^2)}{\frac{\pi}{4}(0.5\,\text{mm})^2(2\times10^{11}\ \text{N/m}^2)} = \frac{(0.7\,\text{mm})^2(0.7\times10^{11}\ \text{N/m}^2)}{(0.5\,\text{mm})^2(2\times10^{11}\ \text{N/m}^2)} = \boxed{0.686}$$

64 ••

Picture the Problem The free-body diagram shows the forces acting on the ball as it rotates around the post in a horizontal plane. We can apply Newton's 2nd law to find the tension in the wire and use the definition of Young's modulus to find the amount by which the aluminum wire stretches.



Express the length of the wire under tension to its unstretched length:

$$L = L_0 + \Delta L = 0.7\,\text{m} + \Delta L \qquad (1)$$

Apply $\sum F_y = 0$ to the ball:

$$T\sin\theta - mg = 0$$

Solve for the tension in the wire:

$$T = \frac{mg}{\sin\theta}$$

Substitute numerical values and evaluate T:

$$T = \frac{(0.5\,\text{kg})(9.81\,\text{m/s}^2)}{\sin 5°} = \boxed{56.3\,\text{N}}$$

Using the definition of Young's modulus, express ΔL:

$$\Delta L = \frac{FL}{AY}$$

Substitute numerical values and evaluate ΔL:

$$\Delta L = \frac{(56.3\,\text{N})(0.7\,\text{m})}{\frac{\pi}{4}(1.6\times10^{-3}\,\text{m})^2(0.7\times10^{11}\,\text{N/m}^2)} = 0.280\,\text{mm}$$

Substitute in equation (1) to obtain:

$$L = 0.7\,\text{m} + 0.280\,\text{mm} = \boxed{70.03\,\text{cm}}$$

***65 ••**

Picture the Problem We can use the definition of stress to calculate the failing stress of the cable and the stress on the elevator cable. Note that the failing stress of the composite cable is the same as the failing stress of the test sample.

Express the stress on the elevator cable:

$$\text{Stress}_{\text{cable}} = \frac{F}{A} = \frac{20\,\text{kN}}{1.2\times10^{-6}\,\text{m}^2} = 1.67\times10^{10}\,\text{N/m}^2$$

Express the failing stress of the sample:

$$\text{Stress}_{\text{failing}} = \frac{F}{A} = \frac{1\text{kN}}{0.2\times10^{-6}\,\text{m}^2} = 0.500\times10^{10}\,\text{N/m}^2$$

$$\boxed{\text{Because Stress}_{\text{failing}} < \text{Stress}_{\text{cable}}\text{, it will not support the elevator.}}$$

***66 •••**

Picture the Problem Let the length of the sides of the rectangle be x, y and z. Then the volume of the rectangle will be $V = xyz$ and we can express the new volume V' resulting from the pulling in the x direction and the change in volume ΔV in terms of Δx, Δy, and Δz. Discarding the higher order terms in ΔV and dividing our equation by V and using the given condition that $\Delta y/y = \Delta z/z$ will lead us to the given expression for $\Delta y/y$.

Express the new volume of the rectangular box when its sides change in length by Δx, Δy, and Δz:

$$V' = (x+\Delta x)(y+\Delta y)(z+\Delta z) = xyz + \Delta x(yz) + \Delta y(xz) + \Delta z(xy) + \{z\Delta x\Delta y + y\Delta x\Delta z + x\Delta y\Delta z + \Delta x\Delta y\Delta z\}$$

where the terms in brackets are very small (i.e., second order or higher).

Discard the second order and higher terms to obtain:

$$V' = V + \Delta x(yz) + \Delta y(xz) + \Delta z(xy)$$

or

$$\Delta V = V' - V = \Delta x(yz) + \Delta y(xz) + \Delta z(xy)$$

Because $\Delta V = 0$:

$$\Delta x(yz) = -[\Delta y(xz) + \Delta z(xy)]$$

Divide both sides of this equation by $V = xyz$ to obtain:

$$\frac{\Delta x}{x} = -\left[\frac{\Delta y}{y} + \frac{\Delta z}{z}\right]$$

Because $\Delta y/y = \Delta z/z$, our equation becomes:

$$\frac{\Delta x}{x} = -2\frac{\Delta y}{y} \text{ or } \frac{\Delta y}{y} = \boxed{-\frac{1}{2}\frac{\Delta x}{x}}$$

67 ••

Picture the Problem We can evaluate the differential of the volume of the wire and, using the assumptions that the volume of the wire does not change under stretching and that the change in its length is small compared to its length, show that $\Delta r/r = -(1/2)\,\Delta L/L$.

Express the volume of the wire:

$$V = \pi r^2 L$$

Evaluate the differential of V to obtain:

$$dV = \pi r^2 dL + 2\pi rLdr$$

Because $dV = 0$:

$$0 = rdL + 2Ldr \Rightarrow \frac{dr}{r} = -\frac{1}{2}\frac{dL}{L}$$

Because $\Delta L << L$, we can approximate the differential changes dr and dL with small changes Δr and ΔL to obtain:

$$\frac{\Delta r}{r} = \boxed{-\frac{1}{2}\frac{\Delta L}{L}}$$

***68** •••

Picture the Problem Because the volume of the thread remains constant during the stretching process, we can equate the initial and final volumes to express r_0 in terms of r. We can also use Young's modulus to express the tension needed to break the thread in terms of Y and r_0.

(*a*) Express the conservation of volume during the stretching of the spider's silk:

$$\pi r^2 L = \pi r_0^2 L_0$$

Solve for r:

$$r = r_0\sqrt{\frac{L_0}{L}}$$

Substitute for L to obtain:

$$r = r_0\sqrt{\frac{L_0}{10L_0}} = \boxed{0.316 r_0}$$

(*b*) Express Young's modulus in terms of the breaking tension T:

$$Y = \frac{T/A}{\Delta L/L} = \frac{T/\pi r^2}{\Delta L/L} = \frac{10T/\pi r_0^2}{\Delta L/L}$$

Solve for T to obtain:

$$T = \frac{1}{10}\pi r_0^2 Y \frac{\Delta L}{L}$$

Because $\Delta L/L = 9$:

$$T = \boxed{\frac{9\pi r_0^2 Y}{10}}$$

General Problems

69 •

Picture the Problem Because the board is in equilibrium, we can apply the conditions for translational and rotational equilibrium to determine the forces exerted by the supports.

Apply $\sum_i \vec{\tau}_i = 0$ about the right support:

$$(2\,\text{m})(360\,\text{N}) + (5\,\text{m})(90\,\text{N}) - (10\,\text{m})F_\text{L} = 0$$

Solve for and evaluate F_L:

$$F_\text{L} = \frac{(2\,\text{m})(360\,\text{N}) + (5\,\text{m})(90\,\text{N})}{10\,\text{m}} = \boxed{117\,\text{N}}$$

Apply $\sum F_y = 0$ to the board:

$$F_\text{L} + F_\text{R} - 90\,\text{N} - 360\,\text{N} = 0$$

Solve for and evaluate F_R:

$$F_\text{R} = -F_\text{L} + 90\,\text{N} + 360\,\text{N} = -117\,\text{N} + 90\,\text{N} + 360\,\text{N} = \boxed{333\,\text{N}}$$

Remarks: **We could just as easily found F_R by applying $\sum \vec{\tau} = 0$ about the left support.**

70 •

Picture the Problem Because the man-and-board system is in equilibrium, we can apply the conditions for translational and rotational equilibrium to determine the forces exerted by the supports. Let d represent the distance from the man's feet to his center of gravity.

Apply $\sum \vec{\tau} = 0$ about an axis through the man's feet and perpendicular to the page:

$$(845\,\text{N})d - (1.88\,\text{m})(445\,\text{N}) = 0$$

Solve for and evaluate d:

$$d = \frac{(1.88\,\text{m})(445\,\text{N})}{845\,\text{N}} = 0.990\,\text{m}$$

$$= \boxed{99.0\,\text{cm}}$$

No. Holding his head slightly above the board would not change the location of his center of mass and so the scale readings would not change.

***71** •

Picture the Problem We can apply the balance condition $\sum \vec{\tau} = 0$ successively, starting with the lowest part of the mobile, to find the value of each of the unknown weights.

Apply $\sum \vec{\tau} = 0$ about an axis through the point of suspension of the lowest part of the mobile:

$$(3\,\text{cm})(2\,\text{N}) - (4\,\text{cm})w_1 = 0$$

Solve for and evaluate w_1:

$$w_1 = \frac{(3\,\text{cm})(2\,\text{N})}{4\,\text{cm}} = \boxed{1.50\,\text{N}}$$

Apply $\sum \vec{\tau} = 0$ about an axis through the point of suspension of the middle part of the mobile:

$$(2\,\text{cm})w_2 - (4\,\text{cm})(2\,\text{N} + 1.5\,\text{N}) = 0$$

Solve for and evaluate w_2:

$$w_2 = \frac{(4\,\text{cm})(2\,\text{N} + 1.5\,\text{N})}{2\,\text{cm}} = \boxed{7.00\,\text{N}}$$

Apply $\sum \vec{\tau} = 0$ about an axis through the point of suspension of the top part of the mobile:

$$(2\,\text{cm})(10.5\,\text{N}) - (6\,\text{cm})w_3 = 0$$

Solve for and evaluate w_3:

$$w_3 = \frac{(2\,\text{cm})(10.5\,\text{N})}{6\,\text{cm}} = \boxed{3.50\,\text{N}}$$

72 •

Picture the Problem We can determine the ratio of L to h by noting the number of ropes supporting the load whose mass is M.

(*a*) Noting that three ropes support the pulley to which the object whose mass is M is fastened we can

$$\frac{L}{h} = \boxed{3}$$

conclude that:

(*b*) Apply the work-energy principle to the block-tackle object to obtain:

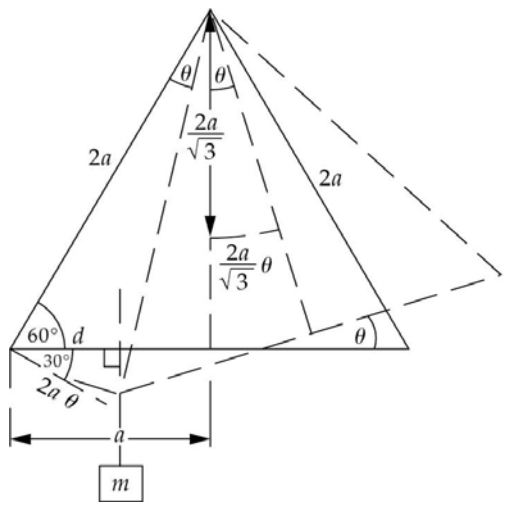
$$W_{ext} = \Delta E_{system} = \Delta U_{block\text{-}tackle}$$

or

$$\boxed{FL = Mgh}$$

73 ••

Picture the Problem The figure shows the equilateral triangle without the mass *m*, and then the same triangle with the mass *m* and rotated through an angle θ. Let the side length of the triangle to be $2a$. Then the center of mass of the triangle is at a distance of $\dfrac{2a}{\sqrt{3}}$ from each vertex. As the triangle rotates, its center of mass shifts by $\dfrac{2a}{\sqrt{3}}\theta$, for $\theta << 1$. Also, the vertex to which *m* is attached moves toward the plumb line by the distance $d = 2a\theta\cos 30° = \sqrt{3}a\theta$ (see the drawing).



Apply $\sum \vec{\tau} = 0$ about an axis through the point of suspension:

$$mg\left(a - \sqrt{3}a\theta\right) - Mg\frac{2a}{\sqrt{3}}\theta = 0$$

Solve for m/M:

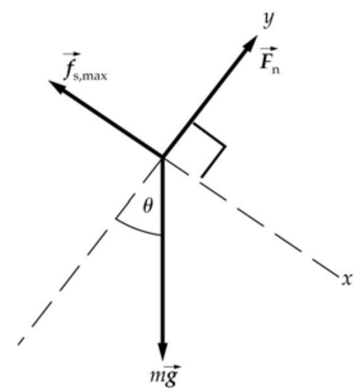
$$\frac{m}{M} = \frac{2\theta}{\sqrt{3}\left(1 - \sqrt{3}\theta\right)}$$

Substitute numerical values and evaluate m/M:

$$\frac{m}{M} = \frac{2(6°)\left(\dfrac{\pi\text{ rad}}{180°}\right)}{\sqrt{3}\left[1 - \sqrt{3}(6°)\left(\dfrac{\pi\text{ rad}}{180°}\right)\right]} = \boxed{0.148}$$

74 ••

Picture the Problem If the hexagon is to roll rather than slide, the incline's angle must be such that the center of mass falls just beyond the support base. From the geometry of the hexagon, one can see that the critical angle is 30°. The free-body diagram shows the forces acting on the hexagonal pencil when it is on the verge of sliding. We can use Newton's 2nd law to relate the coefficient of static friction to the angle of the incline for which rolling rather than sliding occurs.



Apply $\sum \vec{F} = 0$ to the pencil:

$$\sum F_x = mg\sin\theta - f_{s,max} = 0 \quad (1)$$

and

$$\sum F_y = F_n - mg\cos\theta = 0 \quad (2)$$

Substitute $f_{s,max} = \mu_s F_n$ in equation (1):

$$mg\sin\theta - \mu_s F_n = 0 \quad (3)$$

Divide equation (3) by equation (2) to obtain:

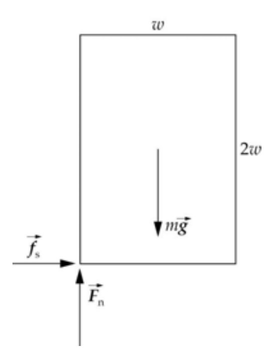
$$\tan\theta = \mu_s$$

Thus, if the pencil is to roll rather than slide when the pad is inclined:

$$\mu_s \geq \tan 30° = \boxed{0.577}$$

75 ••

Picture the Problem The box and the forces acting on it are shown in the figure. When the box is about to tip, F_n acts at its edge, as indicated in the drawing. We can use the definition of μ_s and apply the condition for rotational equilibrium in an accelerated frame to relate f_s to the weight of the box and, hence, to the normal force.



Using its definition, express μ_s:

$$\mu_s \geq \frac{f_s}{F_n}$$

Apply $\sum \vec{\tau} = 0$ about an axis through the box's center of mass:

$$wf_s - \tfrac{1}{2} wF_n = 0$$

Solve for the ratio $\frac{f_s}{F_n}$:

$$\frac{f_s}{F_n} = \frac{1}{2}$$

Substitute to obtain the condition for tipping:

$$\mu_s \geq 0.500$$

Therefore, if the box is to slide:

$$\mu_s < \boxed{0.500}$$

76 ••

Picture the Problem Because the balance is in equilibrium, we can use the condition for rotational equilibrium to relate the masses of the blocks to the lever arms of the balance in the two configurations described in the problem statement.

Apply $\sum \vec{\tau} = 0$ about an axis through the fulcrum:

$$(1.5\,\text{kg})L_1 = (1.95\,\text{kg})L_2$$

Solve for the ratio L_1/L_2:

$$\frac{L_1}{L_2} = \frac{1.95\,\text{kg}}{1.5\,\text{kg}} = 1.30$$

Apply $\sum \vec{\tau} = 0$ about an axis through the fulcrum with 1.5 kg at L_2:

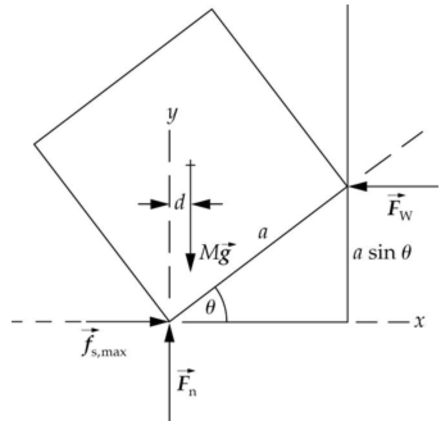
$$(1.5\,\text{kg})L_2 = ML_1$$

Solve for and evaluate M:

$$M = \frac{(1.5\,\text{kg})L_2}{L_1} = \frac{1.5\,\text{kg}}{L_1/L_2} = \frac{1.5\,\text{kg}}{1.30} = \boxed{1.15\,\text{kg}}$$

***77 ••**

Picture the Problem The figure shows the location of the cube's center of mass and the forces acting on the cube. The opposing couple is formed by the friction force $f_{s,max}$ and the force exerted by the wall. Because the cube is in equilibrium, we can use the condition for translational equilibrium to establish that $f_{s,max} = F_W$ and $F_n = Mg$ and the condition for rotational equilibrium to relate the opposing couples.



Apply $\sum \vec{F} = 0$ to the cube:

$$\sum F_y = F_n - Mg = 0 \Rightarrow F_n = Mg$$

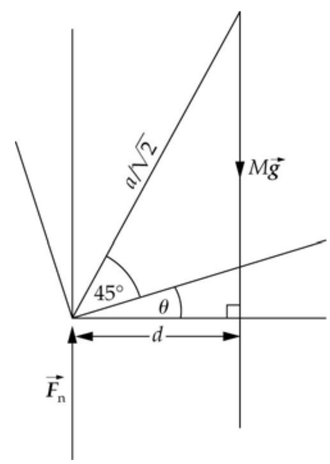
and

$$\sum F_x = f_s - F_W = 0 \Rightarrow F_W = f_s$$

Noting that $\vec{f}_{s,max}$ and $\vec{F}_W$ form a couple, as do $\vec{F}_n$ and $M\vec{g}$, apply $\sum \vec{\tau} = 0$ about an axis though the center of mass of the cube:

$$f_{s,max} a \sin\theta - Mgd = 0$$

Referring to the diagram to the right, note that $d = \dfrac{a}{\sqrt{2}} \sin(45° + \theta)$.



Substitute for d and $f_{s,max}$ to obtain:

$$\mu_s Mga \sin\theta - Mg \frac{a}{\sqrt{2}} \sin(45° + \theta) = 0$$

or

$$\mu_s \sin\theta - \frac{1}{\sqrt{2}} \sin(45° + \theta) = 0$$

Solve for μ_s and simplify to obtain:

$$\mu_s = \frac{1}{\sqrt{2}\sin\theta}\sin(45° + \theta) = \frac{1}{\sqrt{2}\sin\theta}(\sin 45° \cos\theta + \cos 45° \sin\theta)$$

$$= \frac{1}{\sqrt{2}\sin\theta}\left(\frac{1}{\sqrt{2}}\cos\theta + \frac{1}{\sqrt{2}}\sin\theta\right) = \boxed{\frac{1}{2}(\cot\theta + 1)}$$

78 ••

Picture the Problem Because the meter stick is in equilibrium, we can apply the condition for rotational equilibrium to find the maximum distance from the hinge at which the block can be suspended.

Apply $\sum \vec{\tau} = 0$ about an axis through the hinge to obtain:

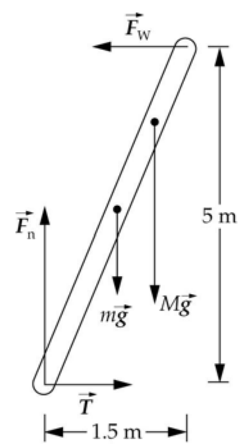
$$(1\,\text{m})(75\,\text{N}) - (0.5\,\text{m})(5\,\text{kg})(9.81\,\text{m/s}^2)\cos 45° - d(10\,\text{kg})(9.81\,\text{m/s}^2)\cos 45° = 0$$

Solve for and evaluate d:

$$d = \frac{(1\,\text{m})(75\,\text{N}) - (0.5\,\text{m})(5\,\text{kg})(9.81\,\text{m/s}^2)}{(10\,\text{kg})(9.81\,\text{m/s}^2)\cos 45°}\cos 45° = \boxed{0.831\,\text{m}}$$

79 ••

Picture the Problem Let m represent the mass of the ladder and M the mass of the person. The force diagram shows the forces acting on the ladder for part (b). From the condition for translational equilibrium, we can conclude that $T = F_W$, a result we'll need in part (b). Because the ladder is also in rotational equilibrium, summing the torques about the bottom of the ladder will eliminate both F_n and T.



(a) Apply $\sum_i \vec{\tau}_i = 0$ about an axis through the bottom of the ladder:

$$(5\,\text{m})F_W - (0.75\,\text{m})(20\,\text{kg})(9.81\,\text{m/s}^2) - (0.75\,\text{m})(80\,\text{kg})(9.81\,\text{m/s}^2) = 0$$

Solve for and evaluate F_W:

$$F_W = \frac{(0.75\,\text{m})(20\,\text{kg})(9.81\,\text{m/s}^2)}{5\,\text{m}} + \frac{(0.75\,\text{m})(80\,\text{kg})(9.81\,\text{m/s}^2)}{5\,\text{m}} = \boxed{147\,\text{N}}$$

(*b*) Solve for and evaluate f:

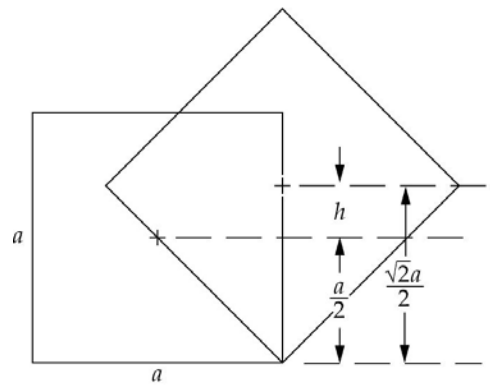
$$f = \frac{(5\,\text{m})(200\,\text{N}) - (0.75\,\text{m})(20\,\text{kg})(9.81\,\text{m/s}^2)}{(1.5\,\text{m})(80\,\text{kg})(9.81\,\text{m/s}^2)} = 0.724$$

Find the distance the 80-kg person can climb the ladder:

$$d = f(5\,\text{m}) = (0.724)(5\,\text{m}) = \boxed{3.62\,\text{m}}$$

***80 ••**

Picture the Problem To ″roll″ the cube one must raise its center of mass from $y = a/2$ to $y = \sqrt{2}a/2$, where a is the cube length. During this process the work done is the change in the gravitational potential energy of the cube. No additional work is done on the cube as it ″flops″ down. We can also use the definition of work to express the work done in sliding the cube a distance a along a horizontal surface and then equate the two expressions to determine μ_k.



Express the work done in moving the cube a distance a by raising its center of mass from $y = a/2$ to $y = \sqrt{2}a/2$ and then letting the cube flop down:

$$W = mg\left(\frac{\sqrt{2}a}{2} - \frac{a}{2}\right) = \frac{mga}{2}\left(\sqrt{2} - 1\right)$$
$$= 0.207mga$$

Letting f_k represent the kinetic friction force, express the work done in dragging the cube a distance a along the surface at constant speed:

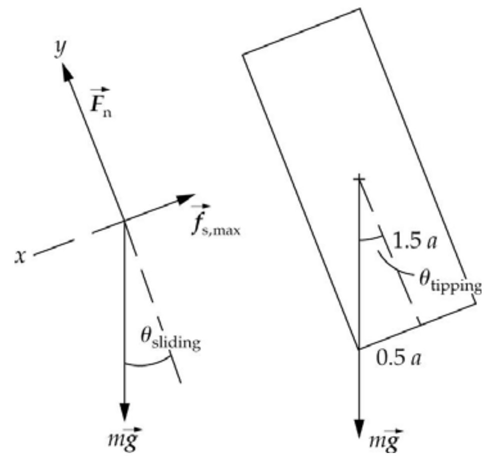
$$W = f_k a = \mu_k mga$$

Equate these two expressions to obtain:

$$\mu_k = \boxed{0.207}$$

81 ••

Picture the Problem The free-body diagram shows the forces acting on the block when it is on the verge of sliding. Because the block is in equilibrium, we can use the conditions for translational equilibrium to determine the minimum angle for which the block will slide. The diagram to the right of the FBD shows that the condition for tipping is that the plumb line from the center of mass pass outside of the base. We can determine the tipping angle from the geometry of the block under this condition.



Apply $\sum \vec{F} = 0$ to the block:

$$\sum F_x = mg\sin\theta_{sliding} - f_{s,max} \geq 0$$

if the block is to slide, and

$$\sum F_y = F_n - mg\cos\theta_{sliding} = 0$$

Substitute for $f_{s,max}$ and eliminate F_n between these equations to obtain:

$$\mu_s \leq \tan\theta_{sliding}$$

Solve for the condition for sliding:

$$\theta_{sliding} \geq \tan^{-1}(\mu_s) = \tan^{-1}(0.4) = 21.8°$$

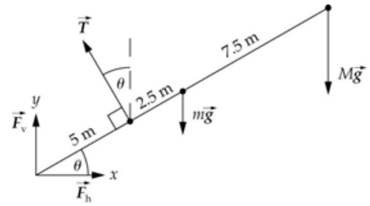
Using the geometry of the block, express the condition on θ that must be satisfied if the block is to tip:

$$\theta_{tipping} \geq \tan^{-1}\left(\frac{0.5a}{1.5a}\right) = \tan^{-1}\left(\frac{1}{3}\right) = 18.4°$$

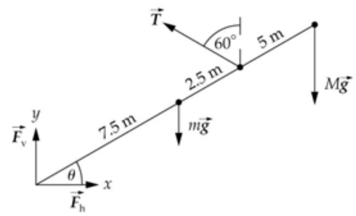
$$\boxed{\text{Because } \theta_{tipping} < \theta_{sliding}\text{, the block will tip before it slides.}}$$

82 ••

Picture the Problem Let m represent the mass of the bar, M the mass of the suspended object, F_v the vertical component of the force the wall exerts on the bar, F_h the horizontal component of the force exerted the wall exerts on the bar, and T the tension in the cable. The free-body diagrams show these forces and their points of application on the bar for parts (a) and (b) of the problem. Because the bar is in equilibrium, we can apply the conditions for translational and rotational equilibrium to relate the various forces and distances.



(a)



(b)

(a) Apply $\sum_i \vec{\tau}_i = 0$ about an axis through the hinge:

$$(5\,\text{m})T - (7.5\,\text{m})mg\cos 30° - (15\,\text{m})Mg\cos 30° = 0$$

Solve for T:

$$T = \frac{[(7.5\,\text{m})m + (15\,\text{m})M]g\cos 30°}{5\,\text{m}}$$

Substitute numerical values and evaluate T:

$$T = \frac{(7.5\,\text{m})(85\,\text{kg}) + (15\,\text{m})(360\,\text{kg})}{5\,\text{m}} \times (9.81\,\text{m/s}^2)\cos 30° = \boxed{10.3\,\text{kN}}$$

Apply $\sum_i \vec{F}_i = 0$ to the bar:

$$\sum F_y = F_\text{v} + T\sin 60° - mg - Mg = 0$$

and

$$\sum F_x = F_\text{h} - T\cos 60° = 0$$

Solve the y equation for F_v:

$$F_\text{v} = -T\sin 60° + (m+M)g = -(10.3\,\text{kN})\sin 60° + (85\,\text{kg} + 360\,\text{kg})(9.81\,\text{m/s}^2) = -4.55\,\text{kN}$$

Solve the x equation for F_h:

$$F_\text{h} = T\cos 60° = (10.3\,\text{kN})\cos 60° = 5.15\,\text{kN}$$

Find the magnitude of the force exerted by the wall on the bar:

$$F = \sqrt{F_{\mathrm{v}}^2 + F_{\mathrm{h}}^2} = \sqrt{(-4.55\,\mathrm{kN})^2 + (5.15\,\mathrm{kN})^2} = \boxed{6.87\,\mathrm{kN}}$$

Find the direction of the force exerted by the wall on the bar:

$$\theta = \tan^{-1}\left(\frac{F_{\mathrm{v}}}{F_{\mathrm{h}}}\right) = \tan^{-1}\left(\frac{-4.55\,\mathrm{kN}}{5.15\,\mathrm{kN}}\right) = \boxed{-41.5°}$$

i.e., 41.5° below the horizontal.

(*b*) Apply $\sum \vec{\tau} = 0$ about the hinge:

$$[(10\,\mathrm{m})\sin 60°]T - (7.5\,\mathrm{m})mg\cos 30° - (15\,\mathrm{m})Mg\cos 30° = 0$$

Solve for *T*:

$$T = \frac{(7.5\,\mathrm{m})m + (15\,\mathrm{m})M}{(10\,\mathrm{m})\sin 60°}g\cos 30°$$

Substitute numerical values and evaluate *T*:

$$T = \frac{(7.5\,\mathrm{m})(85\,\mathrm{kg}) + (15\,\mathrm{m})(360\,\mathrm{kg})}{(10\,\mathrm{m})\sin 60°} \times (9.81\,\mathrm{m/s^2})\cos 30° = \boxed{5.92\,\mathrm{kN}}$$

Apply $\sum \vec{F} = 0$ to the bar:

$$\sum F_y = F_{\mathrm{v}} + T\cos 60° - (85\,\mathrm{kg})g - (360\,\mathrm{kg})g = 0$$

and

$$\sum F_x = F_{\mathrm{h}} - T\sin 60° = 0$$

Solve the *y* equation for F_{v}:

$$F_{\mathrm{v}} = -(5.92\,\mathrm{kN})\cos 60° + (85\,\mathrm{kg} + 360\,\mathrm{kg})(9.81\,\mathrm{m/s^2}) = 1.41\,\mathrm{kN}$$

Solve the *x* equation for F_{h}:

$$F_{\mathrm{h}} = T\sin 60° = (5.92\,\mathrm{kN})\sin 60° = 5.13\,\mathrm{kN}$$

Find the magnitude of the force exerted by the wall on the bar:

$$F = \sqrt{F_{\mathrm{v}}^2 + F_{\mathrm{h}}^2} = \sqrt{(1.41\,\mathrm{kN})^2 + (5.13\,\mathrm{kN})^2} = \boxed{5.32\,\mathrm{kN}}$$

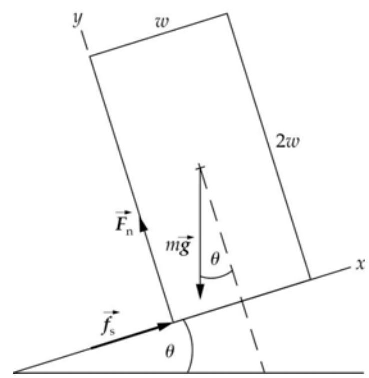
Find the direction of the force exerted by the wall on the bar:

$$\theta = \tan^{-1}\left(\frac{F_v}{F_h}\right) = \tan^{-1}\left(\frac{1.41\,\text{kN}}{5.13\,\text{kN}}\right)$$
$$= \boxed{15.4°}$$

i.e., 15.4° above the horizontal.

83 ••

Picture the Problem The box and the forces acting on it are shown in the figure. When the box is about to tip, F_n acts at its edge, as indicated in the drawing. We can use the definition of μ_s and apply the condition for rotational equilibrium in an accelerated frame to relate f_s to the weight of the box and, hence, to the normal force.



Using its definition, express μ_s:

$$\mu_s \geq \frac{f_s}{F_n}$$

Apply $\sum \vec{\tau} = 0$ about an axis through the box's center of mass:

$$wf_s - \tfrac{1}{2}wF_n = 0$$

Solve for the ratio $\frac{f_s}{F_n}$:

$$\frac{f_s}{F_n} = \frac{1}{2}$$

Substitute to obtain the condition for tipping:

$$\mu_s \geq 0.500$$

Therefore, if the box is to slide:

$\mu_s < \boxed{0.500}$, as in Problem 75.

Remarks: The difference between problems 75 and 83 is that in 75 the maximum acceleration before slipping is 0.5g, whereas in 88 it is (0.5 cos9°– sin9°) = 0.337g.

***84** ••

Picture the Problem Let the mass of the rod be represented by M. Because the rod is in equilibrium, we can apply the condition for rotational equilibrium to relate the masses of the objects placed on it to its mass.

Apply $\sum\vec{\tau}=0$ about an axis through the pivot for the initial condition:

$$(20\,\text{cm})(2m+2\,\text{g})-(40\,\text{cm})m-(10\,\text{cm})M=0$$

Solve for and evaluate M:

$$M=\frac{(20\,\text{cm})(2m+2\,\text{g})-(40\,\text{cm})m}{10\,\text{cm}}=\boxed{4.00\,\text{g}}$$

Apply $\sum\vec{\tau}=0$ about an axis through the pivot for the second condition:

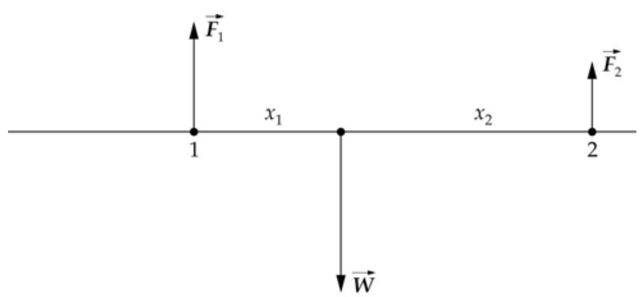
$$(20\,\text{cm})m-(10\,\text{cm})M=0$$

Solve for and evaluate m:

$$m=\frac{(10\,\text{cm})M}{20\,\text{cm}}=\tfrac{1}{2}M=\boxed{2.00\,\text{g}}$$

***85 ••**

Picture the Problem Let the distance from the center of the meterstick of either finger be x_1 and x_2 and W the weight of the stick. Because the meterstick is in equilibrium, we can apply the condition for rotational equilibrium to obtain expressions for the forces one's fingers exert on the meterstick as functions of the distances x_1 and x_2 and the weight of the meterstick W. We can then explain the stop-and-start motion of one's fingers as they are brought closer together by considering the magnitudes of these forces in relationship the coefficients of static and kinetic friction.



(*a*) The stick remains balanced as long as the center of mass is between the two fingers. For a balanced stick the normal force exerted by the finger nearest the center of mass is greater than that exerted by the other finger. Consequently, a larger static-frictional force can be exerted by the finger closer to the center of mass, which means the slipping occurs at the other finger.

(*b*) Apply $\sum \vec{\tau} = 0$ about an axis through point 1 to obtain:

$$F_2(x_1 + x_2) - Wx_1 = 0$$

Solve for F_2 to obtain:

$$F_2 = W\frac{x_1}{x_1 + x_2}$$

Apply $\sum \vec{\tau} = 0$ about an axis through point 2 to obtain:

$$-F_1(x_1 + x_2) + Wx_2 = 0$$

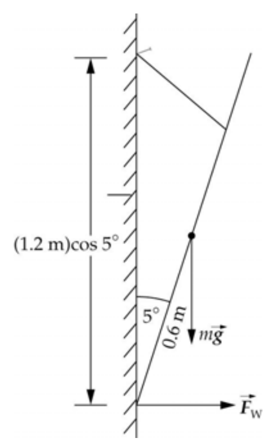
Solve for F_1 to obtain:

$$F_1 = W\frac{x_2}{x_1 + x_2}$$

The finger farthest from the center of mass will slide inward until the normal force it exerts on the stick is sufficiently large to produce a kinetic - frictional force exceeding the maximum static - frictional force exerted by the other finger. At that point the finger that was not sliding begins to slide, the finger that was sliding stops sliding, and the process is reversed. When one finger is is slipping the other is not.

86 ••

Picture the Problem The drawing shows a side view of the wall-and-picture system. Because the frame's width is not specified, we assume it to be negligible. Note that 0.75, 0.4, and 0.85 form a Pythagorean triad. Thus, the nail will be at the same level as the top of the frame. We can apply the condition for rotational equilibrium to determine the force exerted by the wall.



(*a*) Because the center of gravity of the picture is in front of the wall, the torque due to *mg* about the nail must be balanced by an opposing torque due to the force of the wall on the picture, acting horizontally. So that $\sum F_x = 0$, the tension in the wire must have a horizontal component, and the picture must therefore tilt forward.

(*b*) Apply $\sum \vec{\tau} = 0$ about an axis through the nail and parallel to the

$$-[(0.6\,\text{m})\sin 5°](8\,\text{kg})(9.81\,\text{m/s}^2) + [(1.2\,\text{m})\cos 5°]F_W = 0$$

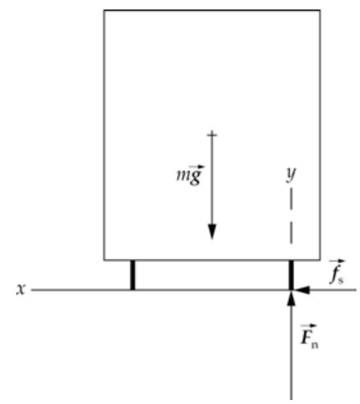
wall to obtain:

Solve for and evaluate F_W:

$$F_W = \frac{[(0.6\,\text{m})\sin 5°](8\,\text{kg})(9.81\,\text{m/s}^2)}{(1.2\,\text{m})\cos 5°} = \boxed{3.43\,\text{N}}$$

87 ••

Picture the Problem The box car and rail are shown in the drawing. At the critical speed, the normal force is entirely on the outside rail. The center of gravity is 0.775 m from that rail and 2.15 m above it. Choose the coordinate system shown in the figure. To find the speed at which this situation prevails, we can apply the conditions for static equilibrium in an accelerated frame.



Apply $\sum \vec{\tau} = 0$ about an axis through the center of gravity of the box car:

$$(0.775\,\text{m})F_n - (2.15\,\text{m})f_s = 0 \qquad (1)$$

Apply $\sum F_y = 0$ to the box car and solve for F_n:

$$F_n - mg = 0 \Rightarrow F_n = mg$$

Apply $\sum F_x = ma_{cm}$ to the box:

$$f_s = m\frac{v^2}{R}$$

Substitute in equation (1) to obtain:

$$(0.775\,\text{m})mg - (2.15\,\text{m})m\frac{v^2}{R} = 0$$

Solve for v:

$$v = \sqrt{0.360Rg}$$

(a) Evaluate v for R = 150 m:

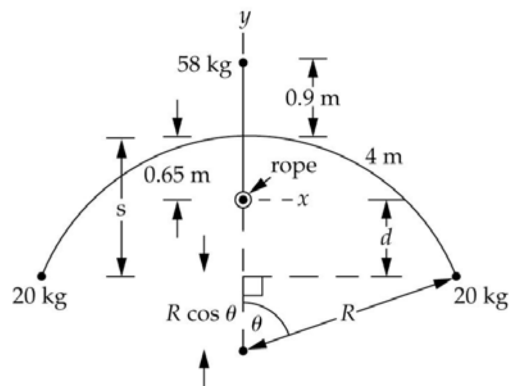
$$v = \sqrt{0.360(150\,\text{m})(9.81\,\text{m/s}^2)} = \boxed{23.0\,\text{m/s}}$$

(*b*) Evaluate v for R = 240 m:

$$v=\sqrt{0.360(240\,\text{m})(9.81\,\text{m/s}^2)}=\boxed{29.1\,\text{m/s}}$$

88 ••

Picture the Problem For neutral equilibrium, the center of mass of the system must be at the same height as the feet of the tightrope walker. The system is shown in the drawing. Let the origin of the coordinate system be at the rope. We'll determine the distance d such that y_{cm} = 0. We'll then determine the angle θ subtended by one half the long rod.



Express the y coordinate of the center of mass of the system:

$$y_{cm}=\frac{(58\,\text{kg})(0.9\,\text{m})-2(20\,\text{kg})d}{58\,\text{kg}+40\,\text{kg}}$$

Set y_{cm} = 0 and solve for d:

d = 1.305 m

Relate the distances s and d and solve for s:

s = 0.65 m + d = 1.955 m

Relate s to R and θ:

$$s=R(1-\cos\theta) \qquad (1)$$

Relate R and θ to the half-length of the rod:

$$R\theta=4\,\text{m} \qquad (2)$$

Substitute in equation (1) to obtain:

$$1.955\,\text{m}=(4\,\text{m})\frac{1-\cos\theta}{\theta}$$

or

$$\frac{1-\cos\theta}{\theta}=0.489$$

Use graphical or trial-and-error methods to solve for θ:

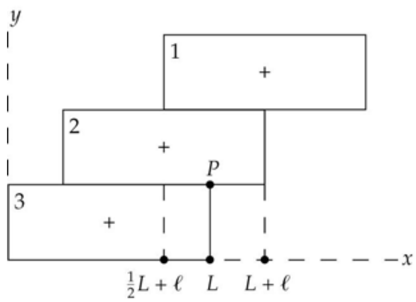
$$\theta=1.08\,\text{rad}$$

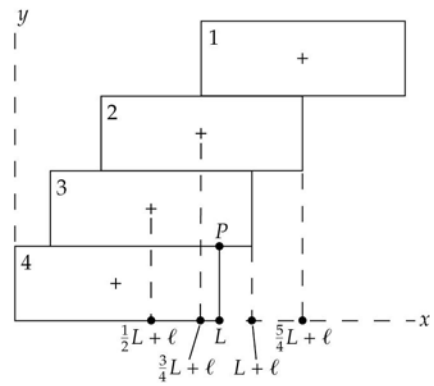
Substitute in equation (2) to obtain:

$$R=\frac{4\,\text{m}}{1.08\,\text{rad}}=\boxed{3.70\,\text{m}}$$

***89** •••

Picture the Problem Let the mass of each brick be m and number them as shown in the diagrams for 3 bricks and 4 bricks below. Let ℓ denote the maximum offset of the nth brick. Choose the coordinate system shown and apply the condition for rotational equilibrium about an axis parallel to the z axis and passing through the point P at the supporting edge of the nth brick.





(*a*) Apply $\sum\vec{\tau}=0$ about an axis through P and parallel to the z axis to bricks 1 and 2 for the 3-brick arrangement shown above on the left:

$$mg\left[L-\left(\tfrac{1}{2}L+\ell\right)\right]-mg\ell=0$$

Solve for ℓ to obtain:

$$\ell=\boxed{\tfrac{1}{4}L}$$

(*b*) Apply $\sum\vec{\tau}=0$ about an axis through P and parallel to the z axis to bricks 1 and 2 for the 4-brick arrangement shown above on the right:

$$mg\left[L-\left(\tfrac{1}{2}L+\ell\right)\right]+mg\left[L-\left(\tfrac{3}{4}L+\ell\right)\right]-mg\left(\tfrac{5}{4}L+\ell-L\right)=0$$

Solve for ℓ to obtain:

$$\ell=\tfrac{1}{6}L$$

Continuing in this manner we obtain, as the successive offsets, the sequence:

$$\boxed{\frac{L}{2},\frac{L}{4},\frac{L}{6},\frac{L}{8},\ldots\frac{L}{2n}}$$

where n = 1, 2, 3, … N.

(c) Express the offset of the (n +1)st brick in terms of the offset of the nth brick:

$$\ell_{n+1}=\ell_n+\frac{L}{2n}$$

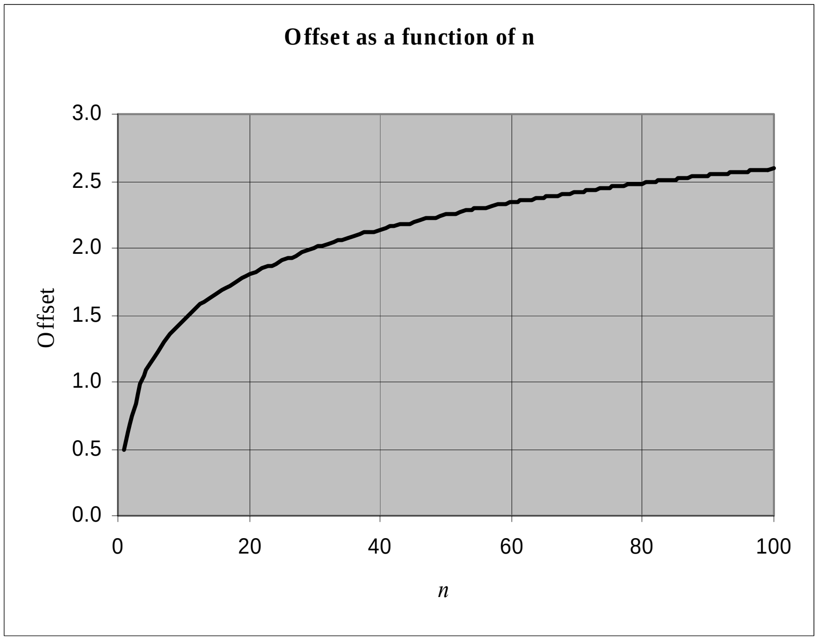
A spreadsheet program to calculate the sum of the offsets as a function of *n* is shown below. The formulas used to calculate the quantities in the columns are as follows:

Cell	Formula/Content	Algebraic Form
B5	B4+1	$n + 1$
C5	C4+$B$1/(2*B5)	$\ell_n + \frac{L}{2n}$

	A	B	C	D
1	L=	1	m	
2				
3		n	offset	
4		1	0.500	
5		2	0.750	
6		3	0.917	
7		4	1.042	
8		5	1.142	
9		6	1.225	
10		7	1.296	
11		8	1.359	
12		9	1.414	
13		10	1.464	
98		95	2.568	
99		96	2.573	
100		97	2.579	
101		98	2.584	
102		99	2.589	
103		100	2.594	

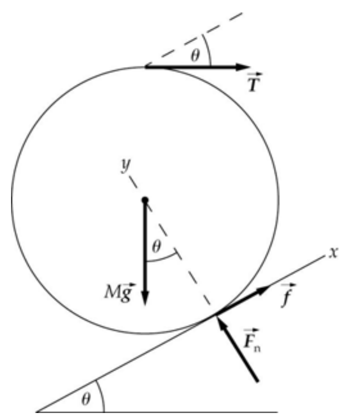
From the table we see that $\ell_5 = \boxed{1.142\text{ m,}}$ $\ell_{10} = \boxed{1.464\text{ m,}}$ and $\ell_{100} = \boxed{2.594\text{ m.}}$

(*d*) Increasing *N* in the spreadsheet solution suggests that the sum of the individual offsets continues to grow as *N* increases without bound. The series is, in fact, divergent and the stack of bricks has no maximum offset or length.



90 •••

Picture the Problem The four forces acting on the sphere: its weight, mg; the normal force of the plane, F_n; the frictional force, f, acting parallel to the plane; and the tension in the string, T, are shown in the figure. Choose the coordinate system shown. Because the sphere is in equilibrium, we can apply the conditions for translational and rotational equilibrium to find f, F_n, and T.



(*a*) Apply $\sum \vec{\tau} = 0$ about an axis through the center of the sphere:

$$fR - TR = 0 \Rightarrow T = f$$

Apply $\sum F_x = 0$ to the sphere:

$$f + T\cos\theta - Mg\sin\theta = 0$$

Substitute for f and solve for T:

$$T = \frac{Mg\sin\theta}{1+\cos\theta}$$

Substitute numerical values and evaluate T:

$$T = \frac{(3\text{ kg})(9.81\text{ m/s}^2)\sin 30°}{1+\cos 30°} = \boxed{7.89\text{ N}}$$

(*b*) Apply $\sum F_y = 0$ to the sphere:

$$F_n - T\sin\theta - Mg\cos\theta = 0$$

Solve for F_n:

$$F_n = T\sin\theta + Mg\cos\theta$$

Substitute numerical values and evaluate F_n:

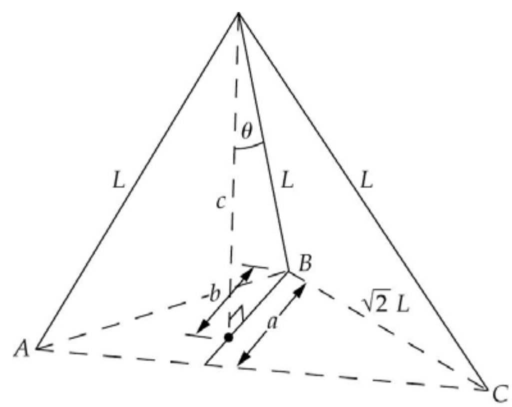
$$F_n = (7.89\,\text{N})\sin 30° + (3\,\text{kg})(9.81\,\text{m/s}^2)\cos 30° = \boxed{29.4\,\text{N}}$$

(*c*) In part (*a*) we showed that $f = T$:

$$f = \boxed{7.89\,\text{N}}$$

91 •••

Picture the Problem Let L be the length of each leg of the tripod. Applying the Pythagorean theorem leads us to conclude that the distance a shown in the figure is $\sqrt{\frac{3}{2}}L$ and the distance b, the distance to the centroid of the triangle ABC is $\frac{2}{3}\sqrt{\frac{3}{2}}L$, and the distance c is $\frac{L}{\sqrt{3}}$. These results allow us to conclude that $\cos\theta = \frac{L}{\sqrt{3}}$. Because the tripod is in equilibrium, we can apply the condition for translational equilibrium to find the compressional forces in each leg.



Letting F_C represent the compressional force in a leg of the tripod, apply $\sum \vec{F} = 0$ to the apex of the tripod:

$$3F_C\cos\theta - mg = 0$$

Solve for F_C:

$$F_C = \frac{mg}{3\cos\theta}$$

Solve for F_C:

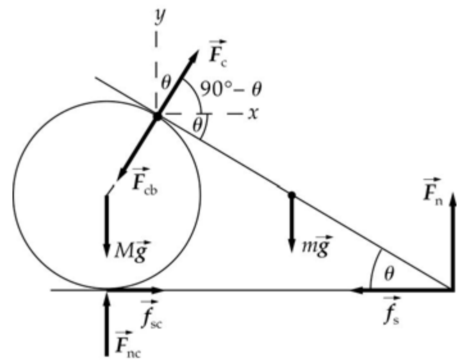
$$F_C = \frac{mg}{3\times\frac{1}{\sqrt{3}}} = \frac{\sqrt{3}}{3}mg$$

Substitute numerical values and evaluate F_C:

$$F_C = \frac{\sqrt{3}}{3}(100\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{566\,\text{N}}$$

92 ••

Picture the Problem The forces that act on the beam are its weight, mg; the force of the cylinder, F_c, acting along the radius of the cylinder; the normal force of the ground, F_n; and the friction force $f_s = \mu_s F_n$. The forces acting on the cylinder are its weight, Mg; the force of the beam on the cylinder, $F_{cb} = F_c$ in magnitude, acting radially inward; the normal force of the ground on the cylinder, F_{nc}; and the force of friction, $f_{sc} = \mu_{sc} F_{nc}$. Choose the coordinate system shown in the figure and apply the conditions for rotational and translational equilibrium.



Express $\mu_{s,\text{beam-floor}}$ in terms of f_s and F_n:

$$\mu_{s,\text{beam-floor}} = \frac{f_s}{F_n} \quad (1)$$

Express $\mu_{s,\text{cylinder-floor}}$ in terms of f_{sc} and F_{nc}:

$$\mu_{s,\text{cylinder-floor}} = \frac{f_{sc}}{F_{nc}} \quad (2)$$

Apply $\sum \vec{\tau} = 0$ about an axis through the right end of the beam:

$$[(10\,\text{cm})\cos\theta]mg - (15\,\text{cm})F_c = 0$$

Solve for and evaluate F_c:

$$F_c = \frac{[(10\,\text{cm})\cos\theta]mg}{15\,\text{cm}} = \frac{[10\cos 30°](5\,\text{kg})(9.81\,\text{m/s}^2)}{15} = 28.3\,\text{N}$$

Apply $\sum F_y = 0$ to the beam:

$$F_n + F_c\cos(90° - \theta) - mg = 0$$

Solve for F_n:

$$F_n = mg - F_c\cos\theta = (5\,\text{kg})(9.81\,\text{m/s}^2) - (28.3\,\text{N})\cos 30° = 24.5\,\text{N}$$

Apply $\sum F_x = 0$ to the beam:

$$-f_s + F_c\cos(90° - \theta) = 0$$

Solve for and evaluate f_s:

$$f_s = F_c\cos(90° - \theta) = (28.3\,\text{N})\cos 60° = 14.2\,\text{N}$$

$\vec{F}_{cb}$ is the reaction force to $\vec{F}_c$:

$F_{cb} = F_c = 28.3\,\text{N}$ radially inward.

Apply $\sum F_y = 0$ to the cylinder:

$$F_{nc} - F_{cb}\cos\theta - Mg = 0$$

Solve for and evaluate F_{nc}:

$$F_{nc} = F_{cb}\cos\theta + Mg = (28.3\,\text{N})\cos 30° + (8\,\text{kg})(9.81\,\text{m/s}^2) = 103\,\text{N}$$

Apply $\sum F_x = 0$ to the cylinder:

$$f_{sc} - F_{cb}\cos(90° - \theta) = 0$$

Solve for and evaluate f_{sc}:

$$f_{sc} = F_{cb}\cos(90° - \theta) = (28.3\,\text{N})\cos 60° = 14.2\,\text{N}$$

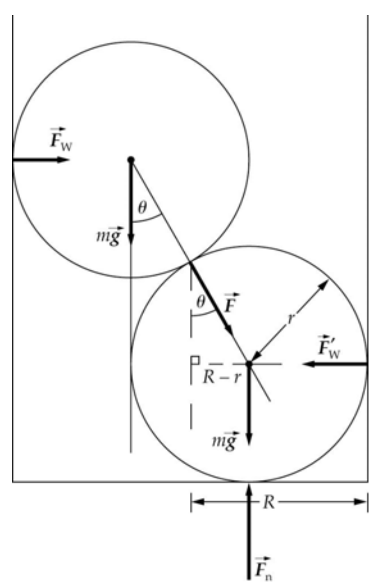
Substitute numerical values in equations (1) and (2) and evaluate $\mu_{s,\text{beam-floor}}$ and $\mu_{s,\text{cylinder-floor}}$:

$$\mu_{s,\text{beam-floor}} = \frac{14.2\,\text{N}}{24.5\,\text{N}} = \boxed{0.580}$$

and

$$\mu_{s,\text{cylinder-floor}} = \frac{14.2\,\text{N}}{103\,\text{N}} = \boxed{0.138}$$

93 •••



Picture the Problem The geometry of the system is shown in the drawing. Let upward be the positive y direction and to the right be the positive x direction. Let the angle between the vertical center line and the line joining the two centers be θ. Then $\sin\theta = \dfrac{R-r}{r}$ and $\tan\theta = \dfrac{R-r}{\sqrt{R(2r-R)}}$.

The force exerted by the bottom of the cylinder is just $2mg$. Let F be the force that the top sphere exerts on the lower sphere. Because the spheres are in equilibrium, we can apply the condition for translational equilibrium.

Apply $\sum F_y = 0$ to the spheres:

$$F_n - mg - mg = 0$$

Solve for F_n: $$F_n = \boxed{2mg}$$

Because the cylinder wall is smooth, $F\cos\theta = mg$, and: $$F = \boxed{\frac{mg}{\cos\theta}}$$

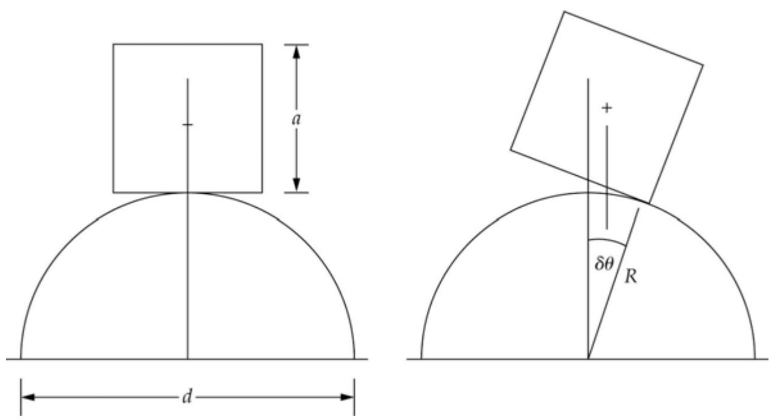
Express the x component of F: $$F_x = F\sin\theta = mg\tan\theta$$

Express the force that the wall of the cylinder exerts: $$F_W = \boxed{mg\frac{R-r}{\sqrt{R(2r-R)}}}$$

Remarks: Note that as r approaches $R/2$, $F_w \to \infty$.

***94 •••**

Picture the Problem Consider a small rotational displacement, $\delta\theta$ of the cube from equilibrium. This shifts the point of contact between cube and cylinder by $R\delta\theta$, where $R = d/2$. As a result of that motion, the cube itself is rotated through the same angle $\delta\theta$, and so its center is shifted in the same direction by the amount $(a/2)\delta\theta$, neglecting higher order terms in $\delta\theta$.



If the displacement of the cube's center of mass is less than that of the point of contact, the torque about the point of contact is a restoring torque, and the cube will return to its equilibrium position. If, on the other hand, $(a/2)\delta\theta > (d/2)\delta\theta$, then the torque about the point of contact due to mg is in the direction of $\delta\theta$, and will cause the displacement from equilibrium to increase. We see that the minimum value of d/a for stable equilibrium is $d/a = 1$.

Chapter 13
Fluids

Conceptual Problems

1 •

Determine the Concept The absolute pressure is related to the gauge pressure according to $P = P_{\text{gauge}} + P_{\text{at}}$. While doubling the gauge pressure will increase the absolute pressure, we do not have enough information to say what the resulting absolute pressure will be. $\boxed{(e)\text{ is correct.}}$

***2** •

Determine the Concept No. In an environment where $g_{\text{eff}} = F_{\text{g}} - m\dfrac{v^2}{r} = 0$, there is no buoyant force; there is no ″up″ or ″down.″

3 ••

Determine the Concept As you lower the rock into the water, the upward force you exert on the rock plus the upward buoyant force on the rock balance its weight. When the thread breaks, there will be an additional downward force on the scale equal to the buoyant force on the rock (the water exerts the upward buoyant force on the rock and the reaction force is the force the rock exerts on the water … and hence on the scale). Let ρ represent the density of the water, V the volume of the rock, and w_{f} the weight of the displaced water. Then the density of the rock is 3ρ. We can use Archimedes' principle to find the additional force on the scale.

Apply Archimedes' principle to the rock: $B = w_{\text{f}} = m_{\text{f}}g = \rho_{\text{f}}V_{\text{f}}g$

Because $V_{\text{f}} = V_{\text{rock}}$:

$$B = \rho\frac{M}{\rho_{\text{rock}}}g = \rho\frac{M}{3\rho}g = \tfrac{1}{3}Mg$$

and $\boxed{(d)\text{ is correct.}}$

4 ••

Determine the Concept The density of water increases with depth and the buoyant force on the rock equals the weight of the displaced water. Because the weight of the displaced water depends on the density of the water, it follows that the buoyant force on the rock increases as it sinks. $\boxed{(b)\text{ is correct.}}$

5 ••

Determine the Concept Nothing. The fish is in neutral buoyancy (that is, its density equals that water), so the upward acceleration of the fish is balanced by the downward acceleration of the displaced water.

***6 ••**

Determine the Concept Yes. Because the volumes of the two objects are equal, the downward force on each side is reduced by the same amount when they are submerged, not in proportion to their masses. That is, if $m_1L_1 = m_2L_2$ and $L_1 \neq L_2$, then $(m_1 - c)L_1 \neq (m_2 - c)L_2$.

7 ••

Determine the Concept The buoyant forces acting on these submerged objects are equal to the weight of the water each displaces. The weight of the displaced water, in turn, is directly proportional to the volume of the submerged object. Because $\rho_{Pb} > \rho_{Cu}$, the volume of the copper must be greater than that of the lead and, hence, the buoyant force on the copper is greater than that on the lead. $\boxed{(b)\text{ is correct.}}$

8 ••

Determine the Concept The buoyant forces acting on these submerged objects are equal to the weight of the water each displaces. The weight of the displaced water, in turn, is directly proportional to the volume of the submerged object. Because their volumes are the same, the buoyant forces on them must be the same. $\boxed{(c)\text{ is correct.}}$

9 •

Determine the Concept It blows over the ball, reducing the pressure above the ball to below atmospheric pressure.

10 •

Determine the Concept From the equation of continuity ($I_V = Av =$ constant), we can conclude that, as the pipe narrows, the velocity of the fluid must increase. Using Bernoulli's equation for constant elevation ($P + \frac{1}{2}\rho v^2 = \text{constant}$), we can conclude that as the velocity of the fluid increases, the pressure must decrease. $\boxed{(b)\text{ is correct.}}$

***11 •**

Determine the Concept False. The buoyant force on a submerged object depends on the weight of the displaced fluid which, in turn, depends on the volume of the displaced fluid.

12 •

Determine the Concept When the bottle is squeezed, the force is transmitted equally through the fluid, leading to a pressure increase on the air bubble in the diver. The air bubble shrinks, and the loss in buoyancy is enough to sink the diver.

13 •

Determine the Concept The buoyant force acting on the ice cubes equals the weight of the water they displace, i.e., $B = w_\mathrm{f} = \rho_\mathrm{f} V_\mathrm{f} g$. When the ice melts the volume of water displaced by the ice cubes will occupy the space previously occupied by the submerged part of the ice cubes. Therefore, the water level remains constant.

14 •

Determine the Concept The density of salt water is greater than that of fresh water and so the buoyant force exerted on one in salt water is greater than in fresh water.

15 ••

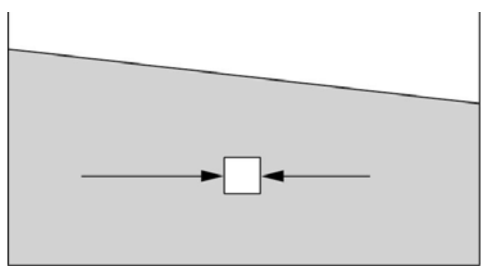
Determine the Concept Because the pressure increases with depth, the object will be compressed and its density will increase. Its volume will decrease. Thus, it will sink to the bottom.

16 ••

Determine the Concept The force acting on the fluid is the difference in pressure between the wide and narrow parts times the area of the narrow part.

17 ••

Determine the Concept The drawing shows the beaker and a strip within the water. As is readily established by a simple demonstration, the surface of the water is not level while the beaker is accelerated, showing that there is a pressure gradient. That pressure gradient results in a net force on the small element shown in the figure.



***18** ••

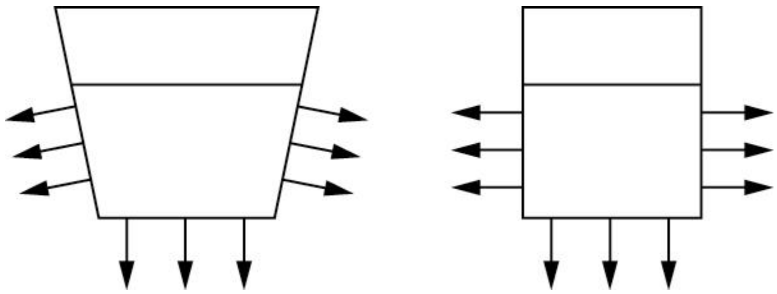
Determine the Concept The water level in the pond will drop slightly. When the anchor is in the boat, the boat displaces enough water so that the buoyant force on it equals the sum of the weight of the boat, your weight, and the weight of the anchor. When you put the anchor overboard, it will displace its volume and the volume of water displaced by the boat will decrease.

19 ••

Determine the Concept From Bernoulli's principle, the opening above which the air flows faster will be at a lower pressure than the other one, which will cause a circulation of air in the tunnel from opening 1 toward opening 2. It has been shown that enough air will circulate inside the tunnel even with the slightest breeze outside.

***20 •**

Determine the Concept The diagram that follows shows the forces exerted by the pressure of the liquid on the two cups to the left.



Because the force is normal to the surface of the cup, there is a larger downward component to the net force on the cup on the left. Similarly, there will be less total force exerted by the fluid in the cup on the far right in the diagram in the problem statement.

Density

21 •

Picture the Problem The mass of the cylinder is the product of its density and volume. The density of copper can be found in Figure 13-1.

Using the definition of density, express the mass of the cylinder:

$$m = \rho V = \rho\left(\pi R^2 h\right)$$

Substitute numerical values and evaluate m:

$$m = \pi\left(8.93\times10^3\ \text{kg/m}^3\right)\left(2\times10^{-2}\ \text{m}\right)^2 \times\left(6\times10^{-2}\ \text{m}\right) = \boxed{0.673\,\text{kg}}$$

22 •

Picture the Problem The mass of the sphere is the product of its density and volume. The density of lead can be found in Figure 13-1.

Using the definition of density, express the mass of the sphere:

$$m = \rho V = \rho\left(\tfrac{4}{3}\pi R^3\right)$$

Substitute numerical values and evaluate m:

$$m = \tfrac{4}{3}\pi\left(11.3\times10^3\ \text{kg/m}^3\right)\left(2\times10^{-2}\ \text{m}\right)^3 = \boxed{0.379\,\text{kg}}$$

23 •

Picture the Problem The mass of the air in the room is the product of its density and volume. The density of air can be found in Figure 13-1.

Using the definition of density, express the mass of the air:

$$m = \rho V = \rho LWH$$

Substitute numerical values and evaluate m:

$$m = (1.293\,\text{kg/m}^3)(4\,\text{m})(5\,\text{m})(4\,\text{m}) = \boxed{103\,\text{kg}}$$

***24** •

Picture the Problem Let ρ_0 represent the density of mercury at 0°C and ρ' its density at 80°C, and let m represent the mass of our sample at 0°C and m' its mass at 80°C. We can use the definition of density to relate its value at the higher temperature to its value at the lower temperature and the amount spilled.

Using its definition, express the density of the mercury at 80°C:

$$\rho' = \frac{m'}{V}$$

Express the mass of the mercury at 80°C in terms of its mass at 0°C and the amount spilled at the higher temperature:

$$\rho' = \frac{m - \Delta m}{V} = \frac{m}{V} - \frac{\Delta m}{V} = \rho_0 - \frac{\Delta m}{V}$$

Substitute numerical values and evaluate ρ':

$$\rho' = 1.3645\times10^4\,\text{kg/m}^3 - \frac{1.47\times10^{-3}\,\text{kg}}{60\times10^{-6}\,\text{m}^3} = \boxed{1.3621\times10^4\,\text{kg/m}^3}$$

Pressure

25 •

Picture the Problem The pressure due to a column of height h of a liquid of density ρ is given by $P = \rho gh$.

Letting h represent the height of the column of mercury, express the pressure at its base:

$$\rho_{\text{Hg}} gh = 101\,\text{kPa}$$

Solve for h:

$$h = \frac{101\,\text{kPa}}{\rho_{\text{Hg}} g}$$

Substitute numerical values and evaluate h:

$$h = \frac{1.01\times10^5\ \text{N/m}^2}{(13.6\times10^3\ \text{kg/m}^3)(9.81\,\text{m/s}^2)}$$
$$= 0.757\,\text{m}\times\frac{1\,\text{in}}{2.54\times10^{-2}\ \text{m}}$$
$$= \boxed{29.8\,\text{in of Hg}}$$

26 •

Picture the Problem The pressure due to a column of height h of a liquid of density ρ is given by $P = \rho gh$.

(a) Express the pressure as a function of depth in the lake:

$$P = P_{\text{at}} + \rho_{\text{water}}gh$$

Solve for and evaluate h:

$$h = \frac{P - P_{\text{at}}}{\rho_{\text{water}}g} = \frac{2P_{\text{at}} - P_{\text{at}}}{\rho_{\text{water}}g} = \frac{P_{\text{at}}}{\rho_{\text{water}}g}$$

Substitute numerical values and evaluate h:

$$h = \frac{1.01\times10^5\ \text{N/m}^2}{(10^3\ \text{kg/m}^3)(9.81\,\text{m/s}^2)}$$
$$= \boxed{10.3\,\text{m}}$$

(b) Proceed as in (a) with ρ_{water} replaced by ρ_{Hg} to obtain:

$$h = \frac{2P_{\text{at}} - P_{\text{at}}}{\rho_{\text{Hg}}g} = \frac{P_{\text{at}}}{\rho_{\text{Hg}}g}$$

Substitute numerical values and evaluate h:

$$h = \frac{1.01\times10^5\ \text{N/m}^2}{(13.6\times10^3\ \text{kg/m}^3)(9.81\,\text{m/s}^2)}$$
$$= \boxed{75.7\,\text{cm}}$$

***27** •

Picture the Problem The pressure applied to an enclosed liquid is transmitted undiminished to every point in the fluid and to the walls of the container. Hence we can equate the pressure produced by the force applied to the piston to the pressure due to the weight of the automobile and solve for F.

Express the pressure the weight of the automobile exerts on the shaft of the lift:

$$P_{\text{auto}} = \frac{w_{\text{auto}}}{A_{\text{shaft}}}$$

Express the pressure the force applied to the piston produces:

$$P = \frac{F}{A_{\text{piston}}}$$

Because the pressures are the same, we can equate them to obtain:

$$\frac{w_{auto}}{A_{shaft}} = \frac{F}{A_{piston}}$$

Solve for F:

$$F = w_{auto}\frac{A_{piston}}{A_{shaft}} = m_{auto}g\frac{A_{piston}}{A_{shaft}}$$

Substitute numerical values and evaluate F:

$$F = (1500\,\text{kg})(9.81\,\text{m/s}^2)\left(\frac{1\,\text{cm}}{8\,\text{cm}}\right)^2$$

$$= \boxed{230\,\text{N}}$$

28 ••

Picture the Problem The pressure exerted by the woman's heel on the floor is her weight divided by the area of her heel.

Using its definition, express the pressure exerted on the floor by the woman's heel:

$$P = \frac{F}{A} = \frac{w}{A} = \frac{mg}{A}$$

Substitute numerical values and evaluate P:

$$P = \frac{(56\,\text{kg})(9.81\,\text{m/s}^2)}{10^{-4}\,\text{m}^2}$$

$$= 5.49\times10^{6}\,\text{N/m}^2 \times \frac{1\,\text{atm}}{101.3\,\text{kPa}}$$

$$= \boxed{54.2\,\text{atm}}$$

***29** •

Picture the Problem The required pressure ΔP is related to the change in volume ΔV and the initial volume V through the definition of the bulk modulus B; $B = -\frac{\Delta P}{\Delta V/V}$.

Using the definition of the bulk modulus, relate the change in volume to the initial volume and the required pressure:

$$B = -\frac{\Delta P}{\Delta V/V}$$

Solve for ΔP:

$$\Delta P = -B\frac{\Delta V}{V}$$

Substitute numerical values and evaluate ΔP:

$$\Delta P = -2.0\times10^{9}\ \text{Pa}\times\left(\frac{-0.01\,\text{L}}{1\,\text{L}}\right) = 2.00\times10^{7}\ \text{Pa}\times\frac{1\,\text{atm}}{101.325\,\text{kPa}} = \boxed{198\,\text{atm}}$$

30 •

Picture the Problem The area of contact of each tire with the road is related to the weight on each tire and the pressure in the tire through the definition of pressure.

Using the definition of gauge pressure, relate the area of contact to the pressure and the weight of the car:

$$A = \frac{\frac{1}{4}w}{P_{\text{gauge}}}$$

Substitute numerical values and evaluate A:

$$A = \frac{\frac{1}{4}(1500\,\text{kg})(9.81\,\text{m/s}^2)}{200\,\text{kPa}} = \frac{\frac{1}{4}(1500\,\text{kg})(9.81\,\text{m/s}^2)}{200\times10^{3}\ \text{N/m}^2} = 1.84\times10^{-2}\ \text{m}^2 = \boxed{184\,\text{cm}^2}$$

31 ••

Picture the Problem The force on the lid is related to pressure exerted by the water and the cross-sectional area of the column of water through the definition of density. We can find the mass of the water from the product of its density and volume.

(*a*) Using the definition of pressure, express the force exerted on the lid:

$$F = PA$$

Express the pressure due to a column of water of height h:

$$P = \rho_{\text{water}}gh$$

Substitute for P and A to obtain:

$$F = \rho_{\text{water}}gh\pi r^2$$

Substitute numerical values:

$$F = (10^{3}\ \text{kg/m}^3)(9.81\,\text{m/s}^2)\times(12\,\text{m})\pi(0.2\,\text{m})^2 = \boxed{14.8\,\text{kN}}$$

(*b*) Relate the mass of the water to its density and volume:

$$m = \rho_{\text{water}}V = \rho_{\text{water}}h\pi r^2$$

Substitute numerical values and evaluate *m*:

$$m = \left(10^3\ \text{kg/m}^3\right)(12\ \text{m})\pi\left(3\times10^{-3}\ \text{m}\right)^2 = \boxed{0.339\ \text{kg}}$$

32 ••

Picture the Problem The minimum elevation of the bag *h* that will produce a pressure of at least 12 mmHg is related to this pressure and the density of the blood plasma through $P = \rho_{\text{blood}}gh$.

Using the definition of the pressure due to a column of liquid, relate the pressure at its base to its height:

$$P = \rho_{\text{blood}}gh$$

Solve for *h*:

$$h = \frac{P}{\rho_{\text{blood}}g}$$

Substitute numerical values and evaluate *h*:

$$h = \frac{12\ \text{mmHg}\times\frac{133.32\ \text{Pa}}{1\ \text{mmHg}}}{\left(1.03\times10^3\ \text{kg/m}^3\right)\left(9.81\ \text{m/s}^2\right)} = 0.158\ \text{m} = \boxed{15.8\ \text{cm}}$$

33 ••

Picture the Problem The depth *h* below the surface at which you would be able to breath is related to the pressure at that depth and the density of water ρ_{w} through $P = \rho_{\text{w}}gh$.

Express the pressure at a depth *h* and solve for *h*:

$$P = \rho_{\text{w}}gh$$

and

$$h = \frac{P}{\rho_{\text{w}}g}$$

Express the pressure at depth *h* in terms of the weight on your chest:

$$P = \frac{F}{A}$$

Substitute to obtain:

$$h = \frac{F}{A\rho_{\text{w}}g}$$

Substitute numerical values and evaluate h:

$$h = \frac{400\,\text{N}}{(0.09\,\text{m}^2)(10^3\,\text{kg/m}^3)(9.81\,\text{m/s}^2)} = \boxed{0.453\,\text{m}}$$

34 ••

Picture the Problem Let A_1 and A_2 represent the cross-sectional areas of the large piston and the small piston, and F_1 and F_2 the forces exerted by the large and on the small piston, respectively. The work done by the large piston is $W_1 = F_1h_1$ and that done on the small piston is $W_2 = F_2h_2$. We'll use Pascal's principle and the equality of the volume of the displaced liquid in both pistons to show that W_1 and W_2 are equal.

Express the work done in lifting the car a distance h:

$$W_1 = F_1h_1$$

where F is the weight of the car.

Using the definition of pressure, relate the forces F_1 (= w) and F_2 to the areas A_1 and A_2:

$$\frac{F_1}{A_1} = \frac{F_2}{A_2}$$

Solve for F_1:

$$F_1 = F_2\frac{A_1}{A_2}$$

Equate the volumes of the displaced fluid in the two pistons:

$$h_1A_1 = h_2A_2$$

Solve for h_1:

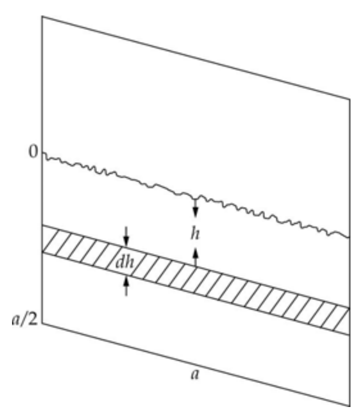
$$h_1 = h_2\frac{A_2}{A_1}$$

Substitute in the expression for W_1 and simplify to obtain:

$$W_1 = F_2\frac{A_1}{A_2}h_2\frac{A_2}{A_1} = F_2h_2 = \boxed{W_2}$$

35 •

Picture the Problem Because the pressure varies with depth, we cannot simply multiply the pressure times the half-area of a side of the cube to find the force exerted by the water. We therefore consider the force exerted on a strip of width a, height dh, and area $dA = adh$ at a depth h and integrate from $h = 0$ to $h = a/2$. The water pressure at depth h is $P_{at} + \rho gh$. We can



omit the atmospheric pressure because it is exerted on both sides of the wall of the cube.

Express the force dF on the element of length a and height dh in terms of the net pressure ρgh:

$$dF = PdA = \rho ghadh$$

Integrate from $h = 0$ to $h = a/2$:

$$F = \int_0^{a/2} dF = \rho ga\int_0^{a/2} hdh = \frac{1}{2}\rho ga\left(\frac{a^2}{4}\right)$$
$$= \boxed{\frac{\rho ga^3}{8}}$$

***36** •••

Picture the Problem The weight of the water in the vessel is the product of its mass and the gravitational field. Its mass, in turn, is related to its volume through the definition of density. The force the water exerts on the base of the container can be determined from the product of the pressure it creates and the area of the base.

(*a*) Using the definition of density, relate the weight of the water to the volume it occupies:

$$w = mg = \rho Vg$$

Substitute for V to obtain:

$$w = \tfrac{1}{3}\pi\rho r^2 hg$$

Substitute numerical values and evaluate w:

$$w = \tfrac{1}{3}\pi\left(10^3\ \text{kg/m}^3\right)\left(15\times10^{-2}\ \text{m}\right)^2\left(25\times10^{-2}\ \text{m}\right)\left(9.81\,\text{m/s}^2\right) = \boxed{57.8\,\text{N}}$$

(*b*) Using the definition of pressure, relate the force exerted by the water on the base of the vessel to the pressure it exerts and the area of the base:

$$F = PA = \rho gh\pi r^2$$

Substitute numerical values and evaluate F:

$$F = \left(10^3\ \text{kg/m}^3\right)\left(9.81\,\text{m/s}^2\right)\left(25\times10^{-2}\ \text{m}\right)\pi\left(15\times10^{-2}\ \text{m}\right)^2 = \boxed{173\,\text{N}}$$

This occurs in the same way that the force on Pascals barrel is much greater than the weight of the water in the tube. The downward force on the base is also the result of the downward component of the force exerted by the slanting walls of the cone on the water.

Buoyancy

***37 •**

Picture the Problem The scale's reading will be the difference between the weight of the piece of copper in air and the buoyant force acting on it.

Express the apparent weight w' of the piece of copper:

$$w' = w - B$$

Using the definition of density and Archimedes' principle, substitute for w and B to obtain:

$$w' = \rho_{\mathrm{Cu}}Vg - \rho_{\mathrm{w}}Vg = (\rho_{\mathrm{Cu}} - \rho_{\mathrm{w}})Vg$$

Express w in terms of ρ_{Cu} and V and solve for Vg:

$$w = \rho_{\mathrm{Cu}}Vg \Rightarrow Vg = \frac{w}{\rho_{\mathrm{Cu}}}$$

Substitute to obtain:

$$w' = (\rho_{\mathrm{Cu}} - \rho_{\mathrm{w}})\frac{w}{\rho_{\mathrm{Cu}}} = \left(1 - \frac{\rho_{\mathrm{w}}}{\rho_{\mathrm{Cu}}}\right)w$$

Substitute numerical values and evaluate w':

$$w' = \left(1 - \frac{1}{9}\right)(0.5\,\mathrm{kg})(9.81\,\mathrm{m/s^2}) = \boxed{4.36\,\mathrm{N}}$$

38 •

Picture the Problem We can use the definition of density and Archimedes' principle to find the density of the stone. The difference between the weight of the stone in air and in water is the buoyant force acting on the stone.

Using its definition, express the density of the stone:

$$\rho_{\mathrm{stone}} = \frac{m_{\mathrm{stone}}}{V_{\mathrm{stone}}} \qquad (1)$$

Apply Archimedes' principle to obtain:

$$B = w_{\mathrm{f}} = m_{\mathrm{f}}g = \rho_{\mathrm{f}}V_{\mathrm{f}}g$$

Solve for V_f:

$$V_f = \frac{B}{\rho_f g}$$

Because $V_f = V_{stone}$ and $\rho_f = \rho_{water}$:

$$V_{stone} = \frac{B}{\rho_{water} g}$$

Substitute in equation (1) and simplify to obtain:

$$\rho_{stone} = \frac{m_{stone} g}{B}\rho_{water} = \frac{w_{stone}}{B}\rho_{water}$$

Substitute numerical values and evaluate ρ_{stone}:

$$\rho_{stone} = \frac{60\,\text{N}}{60\,\text{N} - 20\,\text{N}}\left(10^3\ \text{kg/m}^3\right) = \boxed{3.00\times10^3\ \text{kg/m}^3}$$

39 •

Picture the Problem We can use the definition of density and Archimedes' principle to find the density of the unknown object. The difference between the weight of the object in air and in water is the buoyant force acting on the object.

(*a*) Using its definition, express the density of the object:

$$\rho_{object} = \frac{m_{object}}{V_{object}} \qquad (1)$$

Apply Archimedes' principle to obtain:

$$B = w_f = m_f g = \rho_f V_f g$$

Solve for V_f:

$$V_f = \frac{B}{\rho_f g}$$

Because $V_f = V_{object}$ and $\rho_f = \rho_{water}$:

$$V_{object} = \frac{B}{\rho_{water} g}$$

Substitute in equation (1) and simplify to obtain:

$$\rho_{object} = \frac{m_{object} g}{B}\rho_{water} = \frac{w_{object}}{B}\rho_{water}$$

Substitute numerical values and evaluate ρ_{object}:

$$\rho_{object} = \frac{5\,\text{N}}{5\,\text{N} - 4.55\,\text{N}}\left(10^3\ \text{kg/m}^3\right) = \boxed{11.1\times10^3\ \text{kg/m}^3}$$

(*b*) From Figure 13-1, we see that the unknown material has a density close to that of lead.

40 •

Picture the Problem We can use the definition of density and Archimedes' principle to find the density of the unknown object. The difference between the weight of the object in air and in water is the buoyant force acting on it.

Using its definition, express the density of the metal:

$$\rho_{\text{metal}} = \frac{m_{\text{metal}}}{V_{\text{metal}}} \quad (1)$$

Apply Archimedes' principle to obtain:

$$B = w_{\text{f}} = m_{\text{f}}g = \rho_{\text{f}}V_{\text{f}}g$$

Solve for V_{f}:

$$V_{\text{f}} = \frac{B}{\rho_{\text{f}}g}$$

Because $V_{\text{f}} = V_{\text{metal}}$ and $\rho_{\text{f}} = \rho_{\text{water}}$:

$$V_{\text{metal}} = \frac{B}{\rho_{\text{water}}g}$$

Substitute in equation (1) and simplify to obtain:

$$\rho_{\text{metal}} = \frac{m_{\text{metal}}g}{B}\rho_{\text{water}} = \frac{w_{\text{metal}}}{B}\rho_{\text{water}}$$

Substitute numerical values and evaluate ρ_{metal}:

$$\rho_{\text{metal}} = \frac{90\text{N}}{90\,\text{N} - 56.6\,\text{N}}\left(10^3\ \text{kg/m}^3\right) = \boxed{2.69 \times 10^3\ \text{kg/m}^3}$$

41 ••

Picture the Problem Let V be the volume of the object and V' be the volume that is submerged when it floats. The weight of the object is ρVg and the buoyant force due to the water is $\rho_{\text{w}}V'g$. Because the floating object is translational equilibrium, we can use $\sum F_y = 0$ to relate the buoyant forces acting on the object in the two liquids to its weight.

Apply $\sum F_y = 0$ to the object floating in water:

$$\rho_{\text{w}}V'g - mg = \rho_{\text{w}}V'g - \rho Vg = 0 \quad (1)$$

Solve for ρ:

$$\rho = \rho_{\text{w}}\frac{V'}{V}$$

Substitute numerical values and evaluate ρ:

$$\rho = \left(10^3\ \text{kg/m}^3\right)\frac{0.8V}{V} = \boxed{800\,\text{kg/m}^3}$$

Apply $\sum F_y = 0$ to the object floating in the second liquid and solve for *mg*:

$$mg = 0.72V\rho_L g$$

Solve equation (1) for *mg*:

$$mg = 0.8\rho_w Vg$$

Equate these two expressions to obtain:

$$0.72\rho_L = 0.8\rho_w$$

Substitute in the definition of specific gravity to obtain:

$$\text{specific gravity} = \frac{\rho_L}{\rho_w} = \frac{0.8}{0.72} = \boxed{1.11}$$

***42 ••**

Picture the Problem We can use Archimedes' principle to find the density of the unknown object. The difference between the weight of the block in air and in the fluid is the buoyant force acting on the block.

Apply Archimedes' principle to obtain:

$$B = w_f = m_f g = \rho_f V_f g$$

Solve for ρ_f:

$$\rho_f = \frac{B}{V_f g}$$

Because $V_f = V_{\text{Fe block}}$:

$$\rho_f = \frac{B}{V_{\text{Fe block}}g} = \frac{B}{m_{\text{Fe block}}g}\rho_{\text{Fe}}$$

Substitute numerical values and evaluate ρ_f:

$$\rho_f = \frac{(5\,\text{kg})(9.81\,\text{m/s}^2) - 6.16\,\text{N}}{(5\,\text{kg})(9.81\,\text{m/s}^2)}\left(7.96\times10^3\,\text{kg/m}^3\right) = \boxed{6.96\times10^3\,\text{kg/m}^3}$$

43 ••

Picture the Problem The forces acting on the cork are *B*, the upward force due to the displacement of water, *mg*, the weight of the piece of cork, and F_s, the force exerted by the spring. The piece of cork is in equilibrium under the influence of these forces.

Apply $\sum F_y = 0$ to the piece of cork:

$$B - w - F_s = 0 \qquad (1)$$

or

$$B - \rho_{\text{cork}}Vg - F_s = 0 \qquad (2)$$

Express the buoyant force as a function of the density of water:

$$B = w_f = \rho_w Vg$$

Solve for Vg:

$$Vg = \frac{B}{\rho_w}$$

Substitute for Vg in equation (2):

$$B - \rho_{cork}\frac{B}{\rho_w} - F_s = 0 \qquad (3)$$

Solve equation (1) for B:

$$B = w + F_s$$

Substitute in equation (3) to obtain:

$$w + F_s - \rho_{cork}\frac{w + F_s}{\rho_w} - F_s = 0$$

or

$$w - \rho_{cork}\frac{w + F_s}{\rho_w} = 0$$

Solve for ρ_{cork}:

$$\rho_{cork} = \rho_w \frac{w}{w + F_s}$$

Substitute numerical values and evaluate ρ_{cork}:

$$\rho_{cork} = \left(10^3\ \text{kg/m}^3\right)\frac{0.285\ \text{N}}{0.285\ \text{N} + 0.855\ \text{N}} = \boxed{250\ \text{kg/m}^3}$$

44 ••

Picture the Problem Under minimum-volume conditions, the balloon will be in equilibrium. Let B represent the buoyant force acting on the balloon, w_{tot} represent its total weight, and V its volume. The total weight is the sum of the weights of its basket, cargo, and helium in its balloon.

Apply $\sum F_y = 0$ to the balloon:

$$B - w_{tot} = 0$$

Express the total weight of the balloon:

$$w_{tot} = 2000\ \text{N} + \rho_{He} V g$$

Express the buoyant force due to the displaced air:

$$B = w_f = \rho_{air} V g$$

Substitute to obtain:

$$\rho_{air} V g - 2000\ \text{N} - \rho_{He} V g = 0$$

Solve for V:

$$V = \frac{2000\ \text{N}}{\left(\rho_{air} - \rho_{He}\right)g}$$

Substitute numerical values and evaluate V:

$$V = \frac{2000\,\text{N}}{\left(1.29\,\text{kg/m}^3 - 0.178\,\text{kg/m}^3\right)\left(9.81\,\text{m/s}^2\right)} = \boxed{183\,\text{m}^3}$$

***45 ••**

Picture the Problem Let V = volume of diver, ρ_D the density of the diver, V_{Pb} the volume of added lead, and m_{Pb} the mass of lead. The diver is in equilibrium under the influence of his weight, the weight of the lead, and the buoyant force of the water.

Apply $\sum F_y = 0$ to the diver:

$$B - w_D - w_{Pb} = 0$$

Substitute to obtain:

$$\rho_w V_{D+Pb} g - \rho_D V_D g - m_{Pb} g = 0$$

or

$$\rho_w V_D + \rho_w V_{Pb} - \rho_D V_D - m_{Pb} = 0$$

Rewrite this expression in terms of masses and densities:

$$\rho_w \frac{m_D}{\rho_D} + \rho_w \frac{m_{Pb}}{\rho_{Pb}} - \rho_D \frac{m_D}{\rho_D} - m_{Pb} = 0$$

Solve for the mass of the lead:

$$m_{Pb} = \frac{\rho_{Pb}\left(\rho_w - \rho_D\right) m_D}{\rho_D\left(\rho_{Pb} - \rho_w\right)}$$

Substitute numerical values and evaluate m_{Pb}:

$$m_{Pb} = \frac{\left(11.3\times10^3\,\text{kg/m}^3\right)\left(10^3\,\text{kg/m}^3 - 0.96\times10^3\,\text{kg/m}^3\right)\left(85\,\text{kg}\right)}{\left(0.96\times10^3\,\text{kg/m}^3\right)\left(11.3\times10^3\,\text{kg/m}^3 - 10^3\,\text{kg/m}^3\right)} = \boxed{3.89\,\text{kg}}$$

46 ••

Picture the Problem The scale's reading w' is the difference between the weight of the aluminum block in air w and the buoyant force acting on it. The buoyant force is equal to the weight of the displaced fluid, which, in turn, is the product of its density and mass. We can apply a condition for equilibrium to relate the reading of the bottom scale to the weight of the beaker and its contents and the buoyant force acting on the block.

Express the apparent weight w' of the aluminum block:

$$w' = w - B \qquad (1)$$

Letting F be the reading of the bottom scale and choosing upward to be the positive y direction, apply

$$F + w' - M_{tot} g = 0 \qquad (2)$$

$\sum F_y = 0$ to the scale to obtain:

Using the definition of density and Archimedes' principle, substitute for *w* and *B* in equation (1) to obtain:

$$w' = \rho_{\text{Al}} Vg - \rho_{\text{w}} Vg = (\rho_{\text{Al}} - \rho_{\text{w}})Vg$$

Express *w* in terms of ρ_{Al} and *V* and solve for *Vg*:

$$w = \rho_{\text{Al}} Vg \Rightarrow Vg = \frac{w}{\rho_{\text{Al}}}$$

Substitute to obtain:

$$w' = (\rho_{\text{Al}} - \rho_{\text{w}})\frac{w}{\rho_{\text{Al}}} = \left(1 - \frac{\rho_{\text{w}}}{\rho_{\text{Al}}}\right)w$$

Substitute numerical values and evaluate *w′*:

$$w' = \left(1 - \frac{10^3\ \text{kg/m}^3}{2.7\times10^3\ \text{kg/m}^3}\right) \times (2\ \text{kg})(9.81\ \text{m/s}^2) = \boxed{12.4\ \text{N}}$$

Solve equation (2) for *F*:

$$F = M_{\text{tot}} g - w'$$

Substitute numerical values and evaluate the reading of the bottom scale:

$$F = (5\ \text{kg})(9.81\ \text{m/s}^2) - 12.4\ \text{N} = \boxed{36.7\ \text{N}}$$

47 •••

Picture the Problem Let *V* = displacement of ship in the two cases, *m* be the mass of ship without load, and Δm be the load. The ship is in equilibrium under the influence of the buoyant force exerted by the water and its weight. We'll apply the condition for floating in the two cases and solve the equations simultaneously to determine the loaded mass of the ship.

Apply $\sum F_y = 0$ to the ship in fresh water: $\rho_{\text{w}} Vg - mg = 0$ (1)

Apply $\sum F_y = 0$ to the ship in salt water: $\rho_{\text{sw}} Vg - (m + \Delta m)g = 0$ (2)

Solve equation (1) for *Vg*:

$$Vg = \frac{mg}{\rho_{\text{w}}}$$

Substitute in equation (2) to obtain:

$$\rho_{\text{sw}} \frac{mg}{\rho_{\text{w}}} - (m + \Delta m)g = 0$$

Solve for m:

$$m = \frac{\rho_w \Delta m}{\rho_{sw} - \rho_w}$$

Add Δm to both sides of the equation and simplify to obtain:

$$m + \Delta m = \frac{\rho_w \Delta m}{\rho_{sw} - \rho_w} + \Delta m$$
$$= \Delta m\left(\frac{\rho_w}{\rho_{sw} - \rho_w} + 1\right)$$
$$= \frac{\Delta m \rho_{sw}}{\rho_{sw} - \rho_w}$$

Substitute numerical values and evaluate $m + \Delta m$:

$$m + \Delta m = \frac{(6\times 10^5\ \text{kg})(1.025\rho_w)}{1.025\rho_w - \rho_w}$$
$$= \frac{(6\times 10^5\ \text{kg})(1.025)}{1.025 - 1}$$
$$= \boxed{2.46\times 10^7\ \text{kg}}$$

***48 •••**

Picture the Problem For minimum liquid density, the bulb and its stem will be submerged. For maximum liquid density, only the bulb is submerged. In both cases the hydrometer will be in equilibrium under the influence of its weight and the buoyant force exerted by the liquids.

(*a*) Apply $\sum F_y = 0$ to the hydrometer:

$$B - w = 0$$

Using Archimedes' principle to express B, substitute to obtain:

$$\rho_{min} V g - m_{tot} g = 0$$

or

$$\rho_{min}(V_{bulb} + V_{stem}) = m_{glass} + m_{Pb}$$

Solve for m_{Pb}:

$$m_{Pb} = \rho_{min}(V_{bulb} + V_{stem}) - m_{glass}$$

Substitute numerical values and evaluate m_{Pb}:

$$m_{Pb} = (0.9\,\text{kg/L})\left[0.020\,\text{L} + \frac{\pi}{4}(0.15\,\text{m})(0.005\,\text{m})^2\left(\frac{1\,\text{L}}{10^{-3}\,\text{m}^3}\right)\right] - (6\times 10^{-3}\,\text{kg})$$
$$= \boxed{14.7\,\text{g}}$$

(*b*) Apply $\sum F_y = 0$ to the hydrometer:

$$\rho_{max} V g - m_{tot} g = 0$$

or

$$\rho_{max}V_{bulb} = m_{glass} + m_{Pb}$$

Solve for ρ_{max}:

$$\rho_{max} = \frac{m_{glass} + m_{Pb}}{V_{bulb}}$$

Substitute numerical values and evaluate ρ_{max}:

$$\rho_{max} = \frac{6\,g + 14.7\,g}{20\,mL} = \boxed{1.04\,kg/L}$$

49 •

Picture the Problem We can relate the upward force exerted on the dam wall to the area over which it acts using $F = P_g A$ and express P_g in terms of the depth of the water using $P_g = \rho g h$.

Using the definition of pressure, express the upward force exerted on the dam wall:

$$F = P_g A$$

Express the gauge pressure P_g of the water 5 m below the surface of the dam:

$$P_g = \rho g h$$

Substitute to obtain:

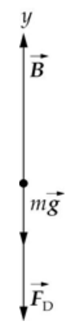
$$F = \rho g h A$$

Substitute numerical values and evaluate F:

$$F = (10^3\,kg/m^3)(9.81\,m/s^2)(5\,m)(10\,m^2) = \boxed{491\,kN}$$

50 ••

Picture the Problem The forces acting on the balloon are the buoyant force B, its weight mg, and a drag force F_D. We can find the initial upward acceleration of the balloon by applying Newton's 2nd law at the instant it is released. We can find the terminal velocity of the balloon by recognizing that when $a_y = 0$, the net force acting on the balloon will be zero.



(*a*) Apply $\sum F_y = ma_y$ to the balloon at the instant of its release to obtain:

$$B - m_{balloon}g = m_{balloon}a_y$$

Solve for a_y:

$$a_y = \frac{B - m_{balloon}g}{m_{balloon}} = \frac{B}{m_{balloon}} - g$$

Using Archimedes principle, express the buoyant force B acting on the balloon:

$$B = w_{\text{f}} = m_{\text{f}} g = \rho_{\text{f}} V_{\text{f}} g = \rho_{\text{air}} V_{\text{balloon}} g = \tfrac{4}{3}\pi \rho_{\text{air}} r^3 g$$

Substitute to obtain:

$$\tfrac{4}{3}\pi \rho_{\text{air}} r^3 g - m_{\text{balloon}} g = m_{\text{balloon}} a_y$$

Solve for a_y:

$$a_y = \left(\frac{\tfrac{4}{3}\pi \rho_{\text{air}} r^3}{m_{\text{balloon}}} - 1\right) g$$

Substitute numerical values and evaluate a_y:

$$a_y = \left[\frac{\tfrac{4}{3}\pi \left(1.29\,\text{kg/m}^3\right)\left(2.5\,\text{m}\right)^3}{15\,\text{kg}} - 1\right] \times \left(9.81\,\text{m/s}^2\right) = \boxed{45.4\,\text{m/s}^2}$$

(*b*) Apply $\sum F_y = ma_y$ to the balloon under terminal-speed conditions to obtain:

$$B - mg - \tfrac{1}{2}\pi r^2 \rho v_{\text{t}}^2 = 0$$

Substitute for B:

$$\tfrac{4}{3}\pi \rho_{\text{air}} r^3 g - mg - \tfrac{1}{2}\pi r^2 \rho v_{\text{t}}^2 = 0$$

Solve for v_{t}:

$$v_{\text{t}} = \sqrt{\frac{2\left(\tfrac{4}{3}\pi \rho_{\text{air}} r^3 - m\right) g}{\pi r^2 \rho}}$$

Substitute numerical values and evaluate v:

$$v_{\text{t}} = \sqrt{\frac{2\left[\tfrac{4}{3}\pi \left(1.29\,\text{kg/m}^3\right)\left(2.5\,\text{m}\right)^3 - 15\,\text{kg}\right]\left(9.81\,\text{m/s}^2\right)}{\pi \left(2.5\,\text{m}\right)^2 \left(1.29\,\text{kg/m}^3\right)}} = \boxed{7.33\,\text{m/s}}$$

(*c*) Relate the time required for the balloon to rise to 10 km to its terminal speed:

$$\Delta t = \frac{h}{v_t} = \frac{10\,\text{km}}{7.33\,\text{m/s}} = 1364\,\text{s} = \boxed{22.7\,\text{min}}$$

Continuity and Bernoulli's Equation

***51 ••**

Picture the Problem Let J represent the flow rate of the water. Then we can use $J = Av$ to relate the flow rate to the cross-sectional area of the circular tap and the velocity of the water. In (*b*) we can use the equation of continuity to express the diameter of the stream 7.5 cm below the tap and a constant-acceleration equation to find the velocity of the water at this distance. In (*c*) we can use a constant-acceleration equation to express the distance-to-turbulence in terms of the velocity of the water at turbulence v_{t} and the definition of Reynolds number N_{R} to relate v_{t} to N_{R}.

(*a*) Express the flow rate of the water in terms of the cross-sectional area A of the circular tap and the velocity v of the water:

$$J = Av = \pi r^2 v = \tfrac{1}{4}\pi d^2 v \qquad (1)$$

Solve for v:

$$v = \frac{J}{\frac{1}{4}\pi d^2}$$

Substitute numerical values and evaluate v:

$$v = \frac{10.5\,\text{cm}^3/\text{s}}{\frac{1}{4}\pi(1.2\,\text{cm})^2} = \boxed{9.28\,\text{cm/s}}$$

(*b*) Apply the equation of continuity to the stream of water:

$$v_\text{f} A_\text{f} = v_\text{i} A_\text{i} = vA_\text{i}$$

or

$$v_\text{f}\frac{\pi}{4}d_\text{f}^2 = v\frac{\pi}{4}d_\text{i}^2$$

Solve for d_f:

$$d_\text{f} = \sqrt{\frac{v}{v_\text{f}}}d_\text{i} \qquad (2)$$

Use a constant-acceleration equation to relate v_f and v to the distance Δh fallen by the water:

$$v_\text{f}^2 = v^2 + 2g\Delta h$$

Solve for v_f to obtain:

$$v_\text{f} = \sqrt{v^2 + 2g\Delta h}$$

Substitute numerical values and evaluate v_f:

$$v_\text{f} = \sqrt{(9.28\,\text{cm/s})^2 + 2(981\,\text{cm/s}^2)(7.5\,\text{cm})} = 122\,\text{cm/s}$$

Substitute in equation (2) and evaluate d_f:

$$d_\text{f} = (1.2\,\text{cm})\sqrt{\frac{9.28\,\text{cm/s}}{122\,\text{cm/s}}} = \boxed{0.331\,\text{cm}}$$

(*c*) Using a constant-acceleration equation, relate the fall-distance-to-turbulence Δd to its initial speed v and its speed v_t when its flow becomes turbulent:

$$v_\text{t}^2 = v^2 + 2g\Delta d$$

Solve for Δd to obtain:

$$\Delta d = \frac{v_\text{t}^2 - v^2}{2g} \qquad (3)$$

Express Reynolds number N_R for turbulent flow:

$$N_\text{R} = \frac{2r\rho v_\text{t}}{\eta}$$

From equation (1):

$$r = \sqrt{\frac{J}{\pi v_t}}$$

Substitute to obtain:

$$N_R = \frac{2\rho v_t}{\eta}\sqrt{\frac{J}{\pi v_t}}$$

Solve for v_t:

$$v_t = \frac{\pi N_R^2 \eta^2}{4\rho^2 J}$$

Substitute numerical values (see Figure 13-1 for the density of water and Table 13-1 for the coefficient of viscosity for water) and evaluate v_t:

$$v_t = \frac{\pi(2300)^2(1.8\times10^{-3}\ \text{Pa}\cdot\text{s})^2}{4(10^3\ \text{kg/m}^3)^2(10.5\,\text{cm}^3/\text{s})}$$
$$= 1.28\,\text{m/s}$$

Substitute in equation (3) and evaluate the fall-distance-to turbulence:

$$\Delta d = \frac{(128\,\text{cm/s})^2 - (9.28\,\text{cm/s})^2}{2(981\,\text{cm/s}^2)}$$
$$= \boxed{8.31\,\text{cm}}$$

in reasonable agreement with everyday experience.

52 •

Picture the Problem Let A_1 represent the cross-sectional area of the hose, A_2 the cross-sectional area of the nozzle, v_1 the velocity of the water in the hose, and v_2 the velocity of the water as it passes through the nozzle. We can use the continuity equation to find v_2 and Bernoulli's equation for constant elevation to find the pressure at the pump.

(*a*) Using the continuity equation, relate the speeds of the water to the diameter of the hose and the diameter of the nozzle:

$$A_1 v_1 = A_2 v_2$$

or

$$\frac{\pi d_1^2}{4} v_1 = \frac{\pi d_2^2}{4} v_2$$

Solve for v_2:

$$v_2 = \frac{d_1^2}{d_2^2} v_1$$

Substitute numerical values and evaluate v_2:

$$v_2 = \left(\frac{3\,\text{cm}}{0.3\,\text{cm}}\right)^2 (0.65\,\text{m/s}) = \boxed{65.0\,\text{m/s}}$$

(*b*) Using Bernoulli's equation for constant elevation, relate the pressure at the pump P_P to the

$$P_P + \tfrac{1}{2}\rho v_1^2 = P_{at} + \tfrac{1}{2}\rho v_2^2$$

atmospheric pressure and the velocities of the water in the hose and the nozzle:

Solve for the pressure at the pump:

$$P_P = P_{at} + \tfrac{1}{2}\rho\left(v_2^2 - v_1^2\right)$$

Substitute numerical values and evaluate P_P:

$$P_P = 101\,\text{kPa} + \tfrac{1}{2}\left(10^3\,\text{kg/m}^3\right)\left[(65\,\text{m/s})^2 - (0.65\,\text{m/s})^2\right]$$
$$= 2.21\times10^6\,\text{Pa}\times\frac{1\,\text{atm}}{101.325\,\text{kPa}} = \boxed{21.9\,\text{atm}}$$

53 •

Picture the Problem Let A_1 represent the cross-sectional area of the larger-diameter pipe, A_2 the cross-sectional area of the smaller-diameter pipe, v_1 the velocity of the water in the larger-diameter pipe, and v_2 the velocity of the water in the smaller-diameter pipe. We can use the continuity equation to find v_2 and Bernoulli's equation for constant elevation to find the pressure in the smaller-diameter pipe.

(*a*) Using the continuity equation, relate the velocities of the water to the diameters of the pipe:

$$A_1v_1 = A_2v_2$$
or
$$\frac{\pi d_1^2}{4}v_1 = \frac{\pi d_2^2}{4}v_2$$

Solve for and evaluate v_2:

$$v_2 = \frac{d_1^2}{d_2^2}v_1$$

Substitute numerical values and evaluate v_2:

$$v_2 = \left(\frac{d_1}{\tfrac{1}{2}d_1}\right)^2(3\,\text{m/s}) = \boxed{12.0\,\text{m/s}}$$

(*b*) Using Bernoulli's equation for constant elevation, relate the pressures in the two segments of the pipe to the velocities of the water in these segments:

$$P_1 + \tfrac{1}{2}\rho_w v_1^2 = P_2 + \tfrac{1}{2}\rho_w v_2^2$$

Solve for P_2:

$$P_2 = P_1 + \tfrac{1}{2}\rho_w v_1^2 - \tfrac{1}{2}\rho_w v_2^2$$
$$= P_1 + \tfrac{1}{2}\rho_w\left(v_1^2 - v_2^2\right)$$

Substitute numerical values and evaluate P_2:

$$P_2 = 200\,\text{kPa} + \tfrac{1}{2}\left(10^3\ \text{kg/m}^3\right) \times \left[(3\,\text{m/s})^2 - (12\,\text{m/s})^2\right] = \boxed{133\,\text{kPa}}$$

(*c*) Using the continuity equation, evaluate I_{V1}:

$$I_{V1} = A_1 v_1 = \frac{\pi\, d_1^2}{4} v_1 = \frac{\pi\, d_1^2}{4}(3\,\text{m/s})$$

Using the continuity equation, express I_{V2}:

$$I_{V2} = A_2 v_2 = \frac{\pi\, d_2^2}{4} v_2$$

Substitute numerical values and evaluate I_{V2}:

$$I_{V2} = \frac{\pi\left(\frac{d_1}{2}\right)^2}{4}(12\,\text{m/s}) = \frac{\pi\, d_1^2}{4}(3\,\text{m/s})$$

Thus, as we expected would be the case:

$$\boxed{I_{V1} = I_{V2}}$$

54 •

Picture the Problem Let A_1 represent the cross-sectional area of the 2-cm diameter pipe, A_2 the cross-sectional area of the constricted pipe, v_1 the velocity of the water in the 2-cm diameter pipe, and v_2 the velocity of the water in the constricted pipe. We can use the continuity equation to express d_2 in terms of d_1 and to find v_1 and Bernoulli's equation for constant elevation to find the velocity of the water in the constricted pipe.

Using the continuity equation, relate the volume flow rate in the 2-cm diameter pipe to the volume flow rate in the constricted pipe:

$$A_1 v_1 = A_2 v_2$$

or

$$\frac{\pi d_1^2}{4} v_1 = \frac{\pi d_2^2}{4} v_2$$

Solve for d_2:

$$d_2 = d_1 \sqrt{\frac{v_1}{v_2}}$$

Using the continuity equation, relate v_1 to the volume flow rate I_V:

$$v_1 = \frac{I_V}{A_1} = \frac{2.80\,\text{L/s}}{\frac{\pi(0.02\,\text{m})^2}{4}} = 8.91\,\text{m/s}$$

Using Bernoulli's equation for constant elevation, relate the pressures in the two segments of the pipe to the velocities of the water in

$$P_1 + \tfrac{1}{2}\rho_w v_1^2 = P_2 + \tfrac{1}{2}\rho_w v_2^2$$

these segments:

Solve for v_2:

$$v_2 = \sqrt{\frac{2(P_1 - P)}{\rho_w} + v_1^2}$$

Substitute numerical values and evaluate v_2:

$$v_2 = \sqrt{\frac{2(142\,\text{kPa} - 101\,\text{kPa})}{10^3\,\text{kg/m}^3} + (8.91\,\text{m/s})^2}$$
$$= 12.7\,\text{m/s}$$

Substitute and evaluate d_2:

$$d_2 = (2\,\text{cm})\sqrt{\frac{8.91\,\text{m/s}}{12.7\,\text{m/s}}} = \boxed{1.68\,\text{cm}}$$

***55 ••**

Picture the Problem We can use the definition of the volume flow rate to find the volume flow rate of blood in an aorta and to find the total cross-sectional area of the capillaries.

(*a*) Use the definition of the volume flow rate to find the volume flow rate through an aorta:

$$I_V = Av$$

Substitute numerical values and evaluate I_V:

$$I_V = \pi(9\times10^{-3}\,\text{m}^3)(0.3\,\text{m/s})$$
$$= 7.63\times10^{-5}\,\frac{\text{m}^3}{\text{s}}\times\frac{60\,\text{s}}{\text{min}}\times\frac{1\,\text{L}}{10^{-3}\,\text{m}^3}$$
$$= \boxed{4.58\,\text{L/min}}$$

(*b*) Use the definition of the volume flow rate to express the volume flow rate through the capillaries:

$$I_V = A_{\text{cap}}v_{\text{cap}}$$

Solve for the total cross-sectional area of the capillaries:

$$A_{\text{cap}} = \frac{I_V}{v_{\text{cap}}}$$

Substitute numerical values and evaluate A_{cap}:

$$A_{\text{cap}} = \frac{7.63\times10^{-5}\,\text{m}^3/\text{s}}{0.001\,\text{m/s}}$$
$$= 7.63\times10^{-2}\,\text{m}^2 = \boxed{763\,\text{cm}^2}$$

56 ••

Picture the Problem We can apply Bernoulli's equation to points *a* and *b* to determine the rate at which the water exits the tank. Because the diameter of the small pipe is much smaller than the diameter of the tank, we can neglect the velocity of the water at the point *a*. The distance the water travels once it exits the pipe is the product of its speed and the time required to fall the distance $H - h$.

Express the distance x as a function of the exit speed of the water and the time to fall the distance $H - h$:

$$x = v_b \Delta t \qquad (1)$$

Apply Bernoulli's equation to the water at points *a* and *b*:

$$P_a + \rho_w gH + \tfrac{1}{2}\rho_w v_a^2 = P_b + \rho_w g(H-h) + \tfrac{1}{2}\rho_w v_b^2$$

or, because $v_a \approx 0$ and $P_a = P_b = P_{at}$,

$$gH = g(H-h) + \tfrac{1}{2}v_b^2$$

Solve for v_b:

$$v_b = \sqrt{2gh}$$

Using a constant-acceleration equation, relate the time of fall to the distance of fall:

$$\Delta y = v_{0y}\Delta t + \tfrac{1}{2}a(\Delta t)^2$$

or, because $v_{0y} = 0$,

$$H - h = \tfrac{1}{2}g(\Delta t)^2$$

Solve for Δt:

$$\Delta t = \sqrt{\frac{2(H-h)}{g}}$$

Substitute in equation (1) to obtain:

$$x = \sqrt{2gh}\sqrt{\frac{2(H-h)}{g}} = \boxed{2\sqrt{h(H-h)}}$$

57 ••

Picture the Problem Let the subscript 60 denote the 60-cm-radius pipe and the subscript 30 denote the 30-cm-radius pipe. We can use Bernoulli's equation for constant elevation to express P_{30} in terms of v_{60} and v_{30}, the definition of volume flow rate to find v_{60} and the continuity equation to find v_{30}.

Using Bernoulli's equation for constant elevation, relate the pressures in the two pipes to the velocities of the oil:

$$P_{60} + \tfrac{1}{2}\rho v_{60}^2 = P_{30} + \tfrac{1}{2}\rho v_{30}^2$$

Solve for P_{30}:

$$P_{30} = P_{60} + \tfrac{1}{2}\rho\left(v_{60}^2 - v_{30}^2\right) \qquad (1)$$

Use the definition of volume flow rate to find v_{60}:

$$v_{60} = \frac{I_V}{A_{60}} = \frac{2.4\times10^5\,\frac{\text{m}^3}{\text{day}}\times\frac{1\,\text{day}}{24\,\text{h}}\times\frac{1\,\text{h}}{3600\,\text{s}}}{\pi(0.6\,\text{m})^2} = 2.456\,\text{m/s}$$

Using the continuity equation, relate the velocity of the oil in the half-standard pipe to its velocity in the standard pipe:

$$A_{60}v_{60} = A_{30}v_{30}$$

Solve for and evaluate v_{30}:

$$v_{30} = \frac{A_{60}}{A_{30}}v_{60} = \frac{\pi(0.6\,\text{m})^2}{\pi(0.3\,\text{m})^2}(2.456\,\text{m/s}) = 9.824\,\text{m/s}$$

Substitute numerical values in equation (1) and evaluate P_{30}:

$$P_{30} = 180\,\text{kPa} + \tfrac{1}{2}\left(800\,\text{kg/m}^3\right)\left[(2.456\,\text{m/s})^2 - (9.824\,\text{m/s})^2\right] = \boxed{144\,\text{kPa}}$$

***58 ••**

Picture the Problem We'll use its definition to relate the volume flow rate in the pipe to the velocity of the water and the result of Example 13-9 to find the velocity of the water.

Using its definition, express the volume flow rate:

$$I_V = A_1v_1 = \pi r^2 v_1$$

Using the result of Example 13-9, find the velocity of the water upstream from the Venturi meter:

$$v_1 = \sqrt{\frac{2\rho_{Hg}gh}{\rho_w\left(\frac{R_1^2}{R_2^2} - 1\right)}}$$

Substitute numerical values and evaluate v_1:

$$v_1 = \sqrt{\frac{2\left(13.6\times10^3\,\text{kg/m}^3\right)\left(9.81\,\text{m/s}^2\right)(0.024\,\text{m})}{\left(10^3\,\text{kg/m}^3\right)\left[\left(\frac{0.095\,\text{m}}{0.056\,\text{m}}\right)^2 - 1\right]}} = 1.847\,\text{m/s}$$

Substitute numerical values and evaluate I_V:

$$I_V = \frac{\pi}{4}(0.095\,\text{m})^2(1.847\,\text{m/s})$$
$$= 1.309\times10^{-2}\,\text{m}^3/\text{s}$$
$$= \boxed{13.1\,\text{L/s}}$$

59 ••

Picture the Problem We can apply the definition of the volume flow rate to find the mass of water emerging from the hose in 1 s and the definition of momentum to find the momentum of the water. The force exerted on the water by the hose can be found from the rate at which the momentum of the water changes.

(*a*) Using its definition, express the volume flow rate of the water emerging from the hose:

$$I_V = \frac{\Delta V}{\Delta t} = \frac{\Delta m}{\rho_w \Delta t} = Av$$

Solve for Δm:

$$\Delta m = Av\rho_w\Delta t$$

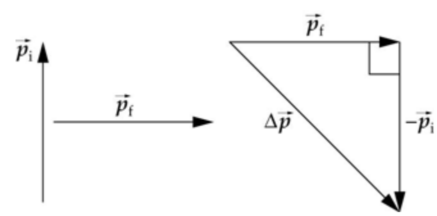
Substitute numerical values and evaluate Δm:

$$\Delta m = \pi(0.015\,\text{m})^2(30\,\text{m/s})(10^3\,\text{kg/m}^3)(1\,\text{s})$$
$$= \boxed{21.2\,\text{kg/s}}$$

(*b*) Using its definition, express and evaluate the momentum of the water:

$$p = \Delta m v = (21.2\,\text{kg/s})(30\,\text{m/s})$$
$$= \boxed{636\,\text{kg}\cdot\text{m/s}}$$

(*c*) The vector diagrams are to the right:



Express the change in momentum of the water:

$$\Delta\vec{p} = \vec{p}_f - \vec{p}_i$$

Substitute numerical values and evaluate Δp:

$$\Delta p = \sqrt{(636\,\text{kg}\cdot\text{m/s})^2 + (636\,\text{kg}\cdot\text{m/s})^2}$$
$$= (636\,\text{kg}\cdot\text{m/s})\sqrt{2}$$
$$= \boxed{899\,\text{kg}\cdot\text{m/s}}$$

Relate the force exerted on the water by the hose to the rate at which the water's momentum changes and evaluate F:

$$F = \frac{\Delta p}{\Delta t} = \frac{899\,\text{kg}\cdot\text{m/s}}{1\,\text{s}} = \boxed{899\,\text{N}}$$

60 ••

Picture the Problem Let the letter P denote the pump and the 2-cm diameter pipe and the letter N the 1-cm diameter nozzle. We'll use Bernoulli's equation to express the necessary pump pressure, the continuity equation to relate the velocity of the water coming out of the pump to its velocity at the nozzle, and a constant-acceleration equation to relate its velocity at the nozzle to the height to which the water rises.

Using Bernoulli's equation, relate the pressures, areas, and velocities in the pipe and nozzle:

$$P_P + \rho_w g h_P + \tfrac{1}{2}\rho_w v_P^2 = P_N + \rho_w g h_N + \tfrac{1}{2}\rho_w v_N^2$$

or, because $P_N = P_{at}$ and $h_P = 0$,

$$P_P + \tfrac{1}{2}\rho_w v_P^2 = P_N + \rho_w g h_N + \tfrac{1}{2}\rho_w v_N^2$$

Solve for the pump pressure:

$$P_P = P_{at} + \rho_w g h_N + \tfrac{1}{2}\rho_w\left(v_N^2 - v_P^2\right) \quad (1)$$

Use the continuity equation to relate v_P and v_N to the cross-sectional areas of the pipe from the pump and the nozzle:

$$A_P v_P = A_N v_N$$

and

$$v_P = \frac{A_N}{A_P} v_N = \frac{\frac{1}{4}\pi d_N^2}{\frac{1}{4}\pi d_P^2} v_N = \left(\frac{1\,\text{cm}}{2\,\text{cm}}\right)^2 v_N = \tfrac{1}{4} v_N$$

Using a constant-acceleration equation, express the velocity of the water at the nozzle in terms of the desired height Δh:

$$v^2 = v_N^2 - 2g\Delta h$$

or, because $v = 0$,

$$v_N^2 = 2g\Delta h$$

Substitute in equation (1) to obtain:

$$\begin{aligned} P_P &= P_{at} + \rho_w g h_N + \tfrac{1}{2}\rho_w\left[2g\Delta h - \tfrac{1}{16}(2g\Delta h)\right] = P_{at} + \rho_w g h_N + \tfrac{1}{2}\rho_w\left(\tfrac{15}{8}g\Delta h\right) \\ &= P_{at} + \rho_w g\left(h_N + \tfrac{15}{16}\Delta h\right) \end{aligned}$$

Substitute numerical values and evaluate P_P:

$$P_P = 101\,\text{kPa} + \left(10^3\,\text{kg/m}^3\right)\left(9.81\,\text{m/s}^2\right)\left[3\,\text{m} + \tfrac{15}{16}(12\,\text{m})\right] = \boxed{241\,\text{kPa}}$$

61 •••

Picture the Problem We can apply Bernoulli's equation to points *a* and *b* to determine the rate at which the water exits the tank. Because the diameter of the small pipe is much smaller than the diameter of the tank, we can neglect the velocity of the water at the point *a*. The distance the water travels once it exits the pipe is the product of its velocity and the time required to fall the distance $H - h$. That there are two values of *h* that are equidistant from the point $h = \frac{1}{2}H$ can be shown by solving the quadratic equation that relates *x* to *h* and *H*. That *x* is a maximum for this value of *h* can be established by treating $x = f(h)$ as an extreme-value problem.

(*a*) Express the distance *x* as a function of the exit speed of the water and the time to fall the distance $H - h$:

$$x = v_b \Delta t \qquad (1)$$

Apply Bernoulli's equation to the water at points *a* and *b*:

$$P_a + \rho_w gH + \tfrac{1}{2}\rho_w v_a^2 = P_b + \rho_w g(H-h) + \tfrac{1}{2}\rho_w v_b^2$$

or, because $v_a \approx 0$ and $P_a = P_b = P_{at}$,

$$gH = g(H-h) + \tfrac{1}{2}v_b^2$$

Solve for v_b:

$$v_b = \sqrt{2gh}$$

Using a constant-acceleration equation, relate the time of fall to the distance of fall:

$$\Delta y = v_{0y}\Delta t + \tfrac{1}{2}a(\Delta t)^2$$

or, because $v_{0y} = 0$,

$$H - h = \tfrac{1}{2}g(\Delta t)^2$$

Solve for Δt:

$$\Delta t = \sqrt{\frac{2(H-h)}{g}}$$

Substitute in equation (1) to obtain:

$$x = \sqrt{2gh}\sqrt{\frac{2(H-h)}{g}} = \boxed{2\sqrt{h(H-h)}}$$

(*b*) Square both sides of this equation and simplify to obtain:

$$x^2 = 4hH - 4h^2 \text{ or } 4h^2 - 4Hh + x^2 = 0$$

Solve this quadratic equation to obtain:

$$h = \boxed{\tfrac{1}{2}H \pm \tfrac{1}{2}\sqrt{H^2 - x^2}}$$

Find the average of these two values for h:

$$h_{av} = \frac{\frac{1}{2}H + \sqrt{H^2 - x^2} + \frac{1}{2}H - \sqrt{H^2 - x^2}}{2}$$

$$= \boxed{\tfrac{1}{2}H}$$

(c) Differentiate $x = 2\sqrt{h(H-h)}$ with respect to h:

$$\frac{dx}{dh} = 2\left(\frac{1}{2}\right)\left[h(H-h)\right]^{-\frac{1}{2}}(H-2h)$$

$$= \frac{H-2h}{\sqrt{h(H-h)}}$$

Set the derivative equal to zero for extrema:

$$\frac{H-2h}{\sqrt{h(H-h)}} = 0$$

Solve for h to obtain:

$$h = \boxed{\tfrac{1}{2}H}$$

Evaluate $x = 2\sqrt{h(H-h)}$ with $h = \frac{1}{2}H$:

$$x_{max} = 2\sqrt{\tfrac{1}{2}H\left(H - \tfrac{1}{2}H\right)}$$

$$= \boxed{H}$$

Remarks: To show that this value for *h* corresponds to a *maximum*, one can either show that $\frac{d^2x}{dh^2} < 0$ at $h = \frac{1}{2}H$ or confirm that the graph of *f*(*h*) at $h = \frac{1}{2}H$ is concave downward.

***62 ••**

Picture the Problem Let the numeral 1 denote the opening in the end of the inner pipe and the numeral 2 to one of the holes in the outer tube. We can apply Bernoulli's principle at these locations and solve for the pressure difference between them. By equating this pressure difference to the pressure difference due to the height h of the liquid column we can express v as a function of ρ, ρ_g, g, and h.

Apply Bernoulli's principle at locations 1 and 2 to obtain:

$$P_1 + \tfrac{1}{2}\rho_g v_1^2 = P_2 + \tfrac{1}{2}\rho_g v_2^2$$

where we've ignored the difference in elevation between the two openings.

Solve for the pressure difference $\Delta P = P_1 - P_2$:

$$\Delta P = P_1 - P_2 = \tfrac{1}{2}\rho_g v_2^2 - \tfrac{1}{2}\rho_g v_1^2$$

Express the velocity of the gas at 1:

$v_1 = 0$ because the gas is brought to a halt (i.e., is stagnant) at the opening to the inner pipe.

Express the velocity of the gas at 2:

$v_2 = v$ because the gas flows freely past the holes in the outer ring.

Substitute to obtain:

$$\Delta P = \tfrac{1}{2}\rho_g v^2$$

Letting A be the cross-sectional area of the tube, express the pressure at a depth h in the column of liquid whose density is ρ_1:

$$P_1 = P_2 + \frac{w_{\text{displaced liquid}}}{A} - \frac{B}{A}$$

where $B = \rho_g Ahg$ is the buoyant force acting on the column of liquid of height h.

Substitute to obtain:

$$P_1 = P_2 + \frac{\rho ghA}{A} - \frac{\rho_g ghA}{A}$$
$$= P_2 + (\rho - \rho_g)gh$$

or

$$\Delta P = P_1 - P_2 = (\rho - \rho_g)gh$$

Equate these two expressions for ΔP:

$$\tfrac{1}{2}\rho_g v^2 = (\rho - \rho_g)gh$$

Solve for v^2 to obtain:

$$\boxed{v^2 = \frac{2gh(\rho - \rho_g)}{\rho_g}}$$

Note that the correction for buoyant force due to the displaced gas is very small and that, to a good approximation,

$$v = \sqrt{\frac{2gh\rho}{\rho_g}}.$$

Remarks: Pitot tubes are used to measure the airspeed of airplanes.

63 ••

Picture the Problem Let the letter ″a″ denote the entrance to the siphon tube and the letter ″b″ denote its exit. Assuming streamline flow between these points, we can apply Bernoulli's equation to relate the entrance and exit speeds of the water flowing in the siphon to the pressures at either end, the density of the water, and the difference in elevation between the entrance and exit points. We can use the expression for the pressure as a function of depth in an incompressible fluid to find the pressure at the entrance to the tube in terms of its distance below the surface. We'll also use the equation of continuity to argue that, provided the surface area of the beaker is large compared to the area of the opening of the tube, the entrance speed of the water is approximately zero.

(*a*) Apply Bernoulli's equation at the entrance to the siphon tube (point a) and at its exit (point b):

$$P_a + \tfrac{1}{2}\rho v_a^2 + \rho g(H - h)$$
$$= P_b + \tfrac{1}{2}\rho v_b^2 + \rho g(H - h - d) \quad (1)$$

where H is the height of the containers.

Apply the continuity equation to a point at the surface of the liquid in the container to the left and to point a:

$$v_a A_a = v_{surface} A_{surface}$$

or, because $A_a << A_{surface}$,

$$v_a = v_{surface} = 0$$

Express the pressure at the inlet (point a) and the outlet (point b):

$$P_a = P_{atm} + \rho g(H - h)$$

and

$$P_b = P_{atm} + \rho g(H - h - d)$$

Letting $v_b = v$, substitute in equation (1) to obtain:

$$P_{atm} + \rho g(H - h) + \rho g H = P_{atm} + \rho g(H - h - d) + \tfrac{1}{2}\rho v^2 + \rho g(H - h - d)$$

or, upon simplification,

$$g(H - h) + gH = g(H - h - d) + \tfrac{1}{2}v^2 + g(H - h - d)$$

Solve for v:

$$v = \boxed{\sqrt{2gd}}$$

(*b*) Relate the pressure at the highest part of the tube P_{top} to the pressure at point b:

$$P_{top} + \rho g(H - h) + \tfrac{1}{2}\rho v_h^2 = P_{atm} + \rho g(H - h - d) + \tfrac{1}{2}\rho v_b^2$$

or, because $v_h = v_b$,

$$P_{top} = \boxed{P_{atm} - \rho g d}$$

Remarks: If we let P_{top} = 0, we can use this result to find the maximum theoretical height a siphon can lift water.

Viscous Flow

64 •

Picture the Problem The required pressure difference can be found by applying Poiseuille's law to the viscous flow of water through the horizontal tube.

Using Poiseuille's law, relate the pressure difference between the two ends of the tube to its length, radius, and the volume flow rate of the water:

$$\Delta P = \frac{8\eta L}{\pi r^4} I_V$$

Substitute numerical values and evaluate ΔP:

$$\Delta P = \frac{8(1\,\text{mPa}\cdot\text{s})(0.25\,\text{m})}{\pi(0.6\times10^{-3}\,\text{m})^4}(0.3\,\text{mL/s}) = \boxed{1.47\,\text{kPa}}$$

65 •

Picture the Problem Because the pressure difference is unchanged, we can equate the expressions of Poiseuille's law for the two tubes and solve for the diameter of the tube that would double the flow rate.

Using Poiseuille's law, express the pressure difference required for the radius and volume flow rate of Problem 64:

$$\Delta P = \frac{8\eta L}{\pi r^4} I_V$$

Express the pressure difference required for the radius r' that would double the volume flow rate of Problem 57:

$$\Delta P = \frac{8\eta L}{\pi r'^4}(2I_V)$$

Equate these equations and simplify to obtain:

$$\frac{8\eta L}{\pi r'^4}(2I_V) = \frac{8\eta L}{\pi r^4} I_V$$

or

$$\frac{2}{r'^4} = \frac{1}{r^4}$$

Solve for r':

$$r' = \sqrt[4]{2}r$$

Express d':

$$d' = 2r' = 2\sqrt[4]{2}r = \sqrt[4]{2}d$$

Substitute numerical values and evaluate d':

$$d' = \sqrt[4]{2}(1.2\,\text{mm}) = \boxed{1.43\,\text{mm}}$$

***66** •

Picture the Problem We can apply Poiseuille's law to relate the pressure drop across the capillary tube to the radius and length of the tube, the rate at which blood is flowing through it, and the viscosity of blood.

Using Poiseuille's law, relate the pressure drop to the length and diameter of the capillary tube, the volume flow rate of the blood, and the viscosity of the blood:

$$\Delta P = \frac{8\eta L}{\pi r^4} I_V$$

Solve for the viscosity of the blood:

$$\eta = \frac{\pi r^4 \Delta P}{8 L I_V}$$

Using its definition, express the volume flow rate of the blood:

$$I_V = A_{cap}v = \pi r^2 v$$

Substitute and simplify:

$$\eta = \frac{r^2 \Delta P}{8Lv}$$

Substitute numerical values to obtain:

$$\eta = \frac{(3.5\times10^{-6}\,\text{m})^2(2.60\,\text{kPa})}{8(10^{-3}\,\text{m})\left(\dfrac{10^{-3}\,\text{m}}{1\,\text{s}}\right)} = \boxed{3.98\,\text{mPa}\cdot\text{s}}$$

***67** •

Picture the Problem We can use the definition of Reynolds number to find the velocity of a baseball at which the drag crisis occurs.

Using its definition, relate Reynolds number to the velocity v of the baseball:

$$N_R = \frac{2r\rho v}{\eta}$$

Solve for v:

$$v = \frac{\eta N_R}{2r\rho}$$

Substitute numerical values (see Figure 13-1 for the density of air and Table 13-1 for the coefficient of viscosity for air) and evaluate v:

$$v = \frac{(0.018\,\text{mPa}\cdot\text{s})(3\times10^5)}{2(0.05\,\text{m})(1.293\,\text{kg/m}^3)} = 41.8\,\text{m/s}\times\frac{1\,\text{mi/h}}{0.447\,\text{m/s}} = \boxed{93.4\,\text{mi/h}}$$

Because most major league pitchers can throw a fastball in the low - to mid - 90s, this drag crisis may very well play a role in the game.

Remarks: This is a topic which has been fiercely debated by people who study the physics of baseball.

68 •••

Picture the Problem Let the subscripts ″f″ refer to ″displaced fluid”, ″s″ to ″soda″, and ″g″ to the ″gas″ in the bubble. The free-body diagram shows the forces acting on the bubble prior to reaching its terminal velocity. We can apply Newton’s 2nd law, Stokes′ law, and Archimedes principle to express the terminal velocity of the bubble in terms of its radius, and the viscosity and density of water.

Apply $\sum F_y = ma_y$ to the bubble to obtain:

$$B - m_g g - F_D = ma_y$$

Under terminal speed conditions:

$$B - m_g g - F_D = 0$$

Using Archimedes principle, express the buoyant force B acting on the bubble:

$$B = w_f = m_f g = \rho_f V_f g = \rho_s V_{bubble} g$$

Express the mass of the gas bubble:

$$m_g = \rho_g V_g = \rho_g V_{bubble}$$

Substitute to obtain:

$$\rho_w V_{bubble} g - \rho_g V_{bubble} g - 6\pi\eta a v_t = 0$$

Solve for v_t:

$$v_t = \frac{V_{bubble} g(\rho_s - \rho_g)}{6\pi\eta a}$$

Substitute for V_{bubble} and simplify:

$$v_t = \frac{\frac{4}{3}\pi a^3 g(\rho_s - \rho_g)}{6\pi\eta a} = \frac{2a^2 g(\rho_s - \rho_g)}{9\eta}$$

$$\approx \frac{2a^2 g\rho_s}{9\eta}, \text{ since } \rho_s >> \rho_g.$$

Substitute numerical values and evaluate v_t:

$$v_t = \frac{2(0.5\times10^{-3}\,\text{m})^2(9.81\,\text{m/s}^2)}{9(1.8\times10^{-3}\,\text{Pa}\cdot\text{s})} \times (1.1\times10^3\,\text{kg/m}^3) = \boxed{0.333\,\text{m/s}}$$

Express the rise time Δt in terms of the height of the soda glass h and the terminal speed of the bubble:

$$\Delta t = \frac{h}{v_t}$$

Assuming that a "typical" soda glass has a height of about 15 cm, evaluate Δt:

$$\Delta t = \frac{0.15\,\text{m}}{0.333\,\text{m/s}} = \boxed{0.450\,\text{s}}$$

Remarks: About half a second seems reasonable for the rise time of the bubble.

General Problems

***69 ••**

Picture the Problem We can solve the given equation for the coefficient of roundness C and substitute estimates/assumptions of typical masses and heights for adult males and females.

Express the mass of a person as a function of C, ρ, and h:

$$M = C\rho h^3$$

Solve for C:

$$C = \frac{M}{\rho h^3}$$

Assuming that a "typical" adult male stands 5' 10" (1.78 m) and weighs 170 lbs (77 kg), then:

$$C = \frac{77\,\text{kg}}{(10^3\,\text{kg/m}^3)(1.78\,\text{m})^3} = \boxed{0.0137}$$

Assuming that a "typical" adult female stands 5' 4" (1.63 m) and weighs 110 lbs (50 kg), then:

$$C = \frac{50\,\text{kg}}{(10^3\,\text{kg/m}^3)(1.63\,\text{m})^3} = \boxed{0.0115}$$

70 •

Picture the Problem Let the letter "s" denote the shorter of the two men and the letter "t" the taller man. We can find the difference in weight of the two men using the relationship $M = C\rho h^3$ from Problem 69.

Express the difference in weight of the two men:

$$\Delta w = w_t - w_s = M_t g - M_s g = (M_t - M_s)g$$

Express the masses of the two men:

$$M_s = C\rho h_s^3$$
and
$$M_t = C\rho h_t^3$$

Substitute to obtain:

$$\Delta w = (C\rho h_t^3 - C\rho h_s^3)g = (h_t^3 - h_s^3)C\rho g$$

Assuming that a "typical" adult male stands 5' 10" (1.78 m) and weighs 170 lbs (77 kg), then:

$$C = \frac{77\,\text{kg}}{(10^3\,\text{kg/m}^3)(1.78\,\text{m})^3} = 0.0137$$

Express the heights of the two men in SI units:

$$h_t = 72\,\text{in} \times 2.54\,\text{cm/in} = 1.83\,\text{m}$$
and

$$h_s = 69\,\text{in} \times 2.54\,\text{cm/in} = 1.75\,\text{m}$$

Substitute numerical values (assume that $\rho = 10^3$ kg/m^3) and evaluate Δw:

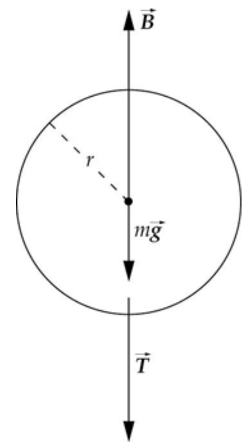
$$\Delta w = \left[(1.83\,\text{m})^3 - (1.75\,\text{m})^3\right] \times (0.0137)\left(10^3\,\text{kg/m}^3\right)\left(9.81\,\text{m/s}^2\right)$$
$$= 103\,\text{N} \times \frac{1\,\text{lb}}{4.4482\,\text{N}} = \boxed{23.2\,\text{lb}}$$

71 •

Determine the Concept The net force is zero. Neglecting the thickness of the table, the atmospheric pressure is the same above and below the surface of the table.

72 •

Picture the Problem The forces acting on the Ping-Pong ball, shown in the free-body diagram, are the buoyant force, the weight of the ball, and the tension in the string. Because the ball is in equilibrium under the influence of these forces, we can apply the condition for translational equilibrium to establish the relationship between them. We can also apply Archimedes' principle to relate the buoyant force on the ball to its diameter.



Apply $\sum F_y = 0$ to the ball:

$$B - mg - T = 0$$

Using Archimedes' principle, relate the buoyant force on the ball to its diameter:

$$B = w_f = m_f g = \rho_w V_{ball} g = \tfrac{1}{6}\pi\rho_w d^3$$

Substitute to obtain:

$$\tfrac{1}{6}\pi\rho_w d^3 - mg - T = 0$$

Solve for d:

$$d = \sqrt[3]{\frac{6(T + mg)}{\pi\rho_w}}$$

Substitute numerical values and evaluate d:

$$d = \sqrt[3]{\frac{6\left[2.8\times10^{-2}\,\text{N} + (0.004\,\text{kg})\left(9.81\,\text{m/s}^2\right)\right]}{\pi\left(10^3\,\text{kg/m}^3\right)}} = \boxed{5.05\,\text{cm}}$$

73 •

Picture the Problem Let ρ_0 represent the density of seawater at the surface. We can use the definition of density and the fact that mass is constant to relate the fractional change in the density of water to its fractional change in volume. We can also use the definition of bulk modulus to relate the fractional change in density to the increase in pressure with depth and solve the resulting equation for the density at the depth at which the pressure is 800 atm.

Using the definition of density, relate the mass of a given volume of seawater to its volume:

$$m = \rho V$$

Noting that the mass does not vary with depth, evaluate its differential:

$$\rho dV + V d\rho = 0$$

Solve for $d\rho/\rho$:

$$\frac{d\rho}{\rho} = -\frac{dV}{V} \text{ or } \frac{\Delta\rho}{\rho} \approx -\frac{\Delta V}{V}$$

Using the definition of the bulk modulus, relate ΔP to $\Delta\rho/\rho_0$:

$$B = -\frac{\Delta P}{\Delta V/V} = \frac{\Delta P}{\Delta\rho/\rho_0}$$

Solve $\Delta\rho$:

$$\Delta\rho = \rho - \rho_0 = \frac{\rho_0 \Delta P}{B}$$

Solve for ρ:

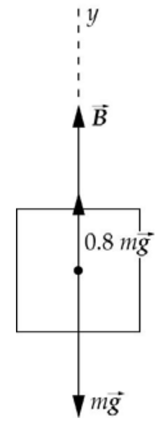
$$\rho = \rho_0 + \frac{\rho_0 \Delta P}{B} = \rho_0\left(1 + \frac{\Delta P}{B}\right)$$

Substitute numerical values and evaluate ρ:

$$\rho = \left(1025\,\text{kg/m}^3\right)\left(1 + \frac{800\,\text{atm} \times \frac{1.01\times10^5\ \text{Pa}}{1\,\text{atm}}}{2.3\times10^9\ \text{N/m}^2}\right) = \boxed{1061\ \text{kg/m}^3}$$

74 •

Picture the Problem When it is submerged, the block is in equilibrium under the influence of the buoyant force due to the water, the force exerted by the spring balance, and its weight. We can use the condition for translational equilibrium to relate the buoyant force to the weight of the block and the definition of density to express the weight of the block in terms of its density.



Apply $\sum F_y = 0$ to the block: $B + 0.8mg - mg = 0 \Rightarrow B = 0.2mg$

Substitute for B and m to obtain: $\rho_w V_{block} g = 0.2\rho_{block} V_{block} g$

Solve for and evaluate ρ_{block}:

$$\rho_{block} = \frac{\rho_w}{0.2} = 5\left(10^3\ \text{kg/m}^3\right) = \boxed{5.00\times10^3\ \text{kg/m}^3}$$

***75** •

Picture the Problem When the copper block is floating on a pool of mercury, it is in equilibrium under the influence of its weight and the buoyant force acting on it. We can apply the condition for translational equilibrium to relate these forces. We can find the fraction of the block that is submerged by applying Archimedes' principle and the definition of density to express the forces in terms of the volume of the block and the volume of the displaced mercury. Let V represent the volume of the copper block, V' the volume of the displaced mercury. Then the fraction submerged when the material is floated on water is V'/V. Choose the upward direction to be the positive y direction.

Apply $\sum F_y = 0$ to the block: $B - w = 0$, where B is the buoyant force and w is the weight of the block.

Apply Archimedes' principle and the definition of density to obtain: $\rho_{Hg} V' g - \rho_{Cu} V g = 0$

Solve for V'/V:

$$\frac{V'}{V} = \frac{\rho_{Cu}}{\rho_{Hg}}$$

Substitute numerical values and evaluate V'/V:

$$\frac{V'}{V}=\frac{8.93\times10^{3}\ \text{kg/m}^{3}}{13.6\times10^{3}\ \text{kg/m}^{3}}=0.657=\boxed{65.7\%}$$

76 •

Picture the Problem When the block is floating on a pool of ethanol, it is in equilibrium under the influence of its weight and the buoyant force acting on it. We can apply the condition for translational equilibrium to relate these forces. We can find the fraction of the block that is submerged by applying Archimedes' principle and the definition of density to express the forces in terms of the volume of the block and the volume of the displaced ethanol. Let V represent the volume of the copper block, V' the volume of the displaced ethanol. Then the fraction of the volume of the block that will be submerged when the material is floated on water is V'/V. Choose the upward direction to be the positive y direction.

Apply $\sum F_y=0$ to the block floating on ethanol:

$B_{\text{eth}}-w=0$, where B_{eth} is the buoyant force due to the ethanol and w is the weight of the block.

Apply Archimedes' principle to obtain:

$$w=\rho_{\text{eth}}(0.9V)g$$

Apply $\sum F_y=0$ to the block floating on water:

$B_{\text{w}}-w=0$, where B_{w} is the buoyant force due to the water and w is the weight of the block.

Apply Archimedes' principle to obtain:

$w=\rho_{\text{w}}V'g$, where V' is the volume of the displaced water.

Equate the two expressions for w and solve for V'/V:

$$\frac{V'}{V}=\frac{0.9\rho_{\text{eth}}}{\rho_{\text{w}}}$$

Substitute numerical values and evaluate V'/V:

$$\frac{V'}{V}=\frac{0.9\left(0.806\times10^{3}\ \text{kg/m}^{3}\right)}{10^{3}\ \text{kg/m}^{3}}$$

$$=0.725=\boxed{72.5\%}$$

77 •

Determine the Concept If you are floating, the density (or specific gravity) of the liquid in which you are floating is immaterial as you are in translational equilibrium under the influence of your weight and the buoyant force on your body. Thus, the buoyant force on your body is your weight in both (*a*) and (*b*).

78 •

Picture the Problem Let m and V represent the mass and volume of your body. Because you are in translational equilibrium when you are floating, we can apply the condition for translational equilibrium and Archimedes' principle to your body to express the dependence of the volume of water it displaces when it is fully submerged on your weight. Let the upward direction be the positive y direction.

Apply $\sum F_y = 0$ to your floating body:

$$B - mg = 0$$

Use Archimedes' principle to relate the density of water to your volume:

$$B = w_f = m_f g = \rho_w (0.96V)g$$

Substitute to obtain:

$$\rho_w (0.96V)g - mg = 0$$

Solve for V:

$$V = \boxed{\frac{m}{0.96\rho_w}}$$

79 ••

Picture the Problem Let m and V represent the mass and volume of the block of wood. Because the block is in translational equilibrium when it is floating, we can apply the condition for translational equilibrium and Archimedes' principle to express the dependence of the volume of water it displaces when it is fully submerged on its weight. We'll repeat this process for the situation in which the lead block is resting on the wood block with the latter fully submerged. Let the upward direction be the positive y direction.

Apply $\sum F_y = 0$ to floating block:

$$B - mg = 0$$

Use Archimedes' principle to relate the density of water to the volume of the block of wood:

$$B = w_f = m_f g = \rho_w (0.68V)g$$

Using the definition of density, express the weight of the block in terms of its density:

$$mg = \rho_{wood} V g$$

Substitute to obtain:

$$\rho_w (0.68V)g - \rho_{wood} V g = 0$$

Solve for and evaluate the density of the wood block:

$$\rho_{wood} = 0.68\rho_w = 0.68(10^3 \text{ kg/m}^3) = 680 \text{ kg/m}^3$$

Use the definition of density to find the volume of the wood:

$$V = \frac{m_{\text{wood}}}{\rho_{\text{wood}}} = \frac{1.5\,\text{kg}}{680\,\text{kg/m}^3} = 2.206\times10^{-3}\,\text{m}^3$$

Apply $\sum F_y = 0$ to the floating block when the lead block is placed on it:

$B' - m'g = 0$, where B' is the new buoyant force on the block and m' is the combined mass of the wood block and the lead block.

Use Archimedes' principle and the definition of density to obtain:

$$\rho_{\text{w}} Vg - (m_{\text{Pb}} + m_{\text{block}})g = 0$$

Solve for the mass of the lead block:

$$m_{\text{Pb}} = \rho_{\text{w}} V - m_{\text{block}}$$

Substitute numerical values and evaluate m_{Pb}:

$$m_{\text{Pb}} = (10^3\,\text{kg/m}^3)(2.206\times10^{-3}\,\text{m}^3) - 1.5\,\text{kg} = \boxed{0.706\,\text{kg}}$$

***80 ••**

Picture the Problem The true mass of the Styrofoam cube is greater than that indicated by the balance due to the buoyant force acting on it. The balance is in rotational equilibrium under the influence of the buoyant and gravitational forces acting on the Styrofoam cube and the brass masses. Neglect the buoyancy of the brass masses. Let *m* and *V* represent the mass and volume of the cube and *L* the lever arm of the balance.

Apply $\sum \vec{\tau} = 0$ to the balance:

$$(mg - B)L - m_{\text{brass}} gL = 0$$

Use Archimedes' principle to express the buoyant force on the Styrofoam cube as a function of volume and density of the air it displaces:

$$B = \rho_{\text{air}} Vg$$

Substitute and simplify to obtain:

$$m - \rho_{\text{air}} V - m_{\text{brass}} = 0$$

Solve for *m*:

$$m = \rho_{\text{air}} V + m_{\text{brass}}$$

Substitute numerical values and evaluate *m*:

$$m = (1.293\,\text{kg/m}^3)(0.25\,\text{m})^3 + 20\times10^{-3}\,\text{kg} = 4.02\times10^{-2}\,\text{kg} = \boxed{40.2\,\text{g}}$$

81 ••

Picture the Problem Let d_{in} and d_{out} represent the inner and outer diameters of the copper shell and V' the volume of the sphere that is submerged. Because the spherical shell is floating, it is in translational equilibrium and we can apply a condition for translational equilibrium to relate the buoyant force B due to the displaced water and its weight w.

Apply $\sum F_y = 0$ to the spherical shell:

$$B - w = 0$$

Using Archimedes' principle and the definition of w, substitute to obtain:

$$\rho_w V'g - mg = 0$$

or

$$\rho_w V' - m = 0 \qquad (1)$$

Express V' as a function d_{out}:

$$V' = \frac{1}{2}\frac{\pi}{6}d_{out}^3 = \frac{\pi}{12}d_{out}^3$$

Express m in terms of d_{in} and d_{out}:

$$m = \rho_{Cu}\left(V_{out} - V_{in}\right) = \rho_{Cu}\left(\frac{\pi}{6}d_{out}^3 - \frac{\pi}{6}d_{in}^3\right)$$

Substitute in equation (1) to obtain:

$$\rho_w\frac{\pi}{12}d_{out}^3 - \rho_{Cu}\left(\frac{\pi}{6}d_{out}^3 - \frac{\pi}{6}d_{in}^3\right) = 0$$

Simplify:

$$\frac{1}{2}\rho_w d_{out}^3 - \rho_{Cu}\left(d_{out}^3 - d_{in}^3\right) = 0$$

Solve for d_{in}:

$$d_{in} = d_{out}\sqrt[3]{1 - \frac{\rho_w}{2\rho_{Cu}}}$$

Substitute numerical values and evaluate d_{in}:

$$d_{in} = (12\,\text{cm})\sqrt[3]{1 - \frac{1}{2(8.93)}} = \boxed{11.8\,\text{cm}}$$

82 ••

Determine the Concept The additional weight on the beaker side equals the weight of the displaced water, i.e., 64 g. This is the mass that must be placed on the other cup to maintain balance.

***83** ••

Picture the Problem We can use the definition of Reynolds number and assume a value for N_R of 1000 (well within the laminar flow range) to obtain a trial value for the radius of the pipe. We'll then use Poiseuille's law to determine the pressure difference between the ends of the pipe that would be required to maintain a volume flow rate of 500 L/s.

Use the definition of Reynolds number to relate N_R to the radius of the pipe:

$$N_R = \frac{2r\rho v}{\eta}$$

Use the definition of I_V to relate the volume flow rate of the pipe to its radius:

$$I_V = Av = \pi r^2 v \Rightarrow v = \frac{I_V}{\pi r^2}$$

Substitute to obtain:

$$N_R = \frac{2\rho I_V}{\eta\pi r}$$

Solve for r:

$$r = \frac{2\rho I_V}{\eta\pi N_R}$$

Substitute numerical values and evaluate r:

$$r = \frac{2(700\,\text{kg/m}^3)(0.500\,\text{m}^3/\text{s})}{\pi(0.8\,\text{Pa}\cdot\text{s})(1000)} = 27.9\,\text{cm}$$

Using Poiseuille's law, relate the pressure difference between the ends of the pipe to its radius:

$$\Delta P = \frac{8\eta L}{\pi r^4} I_V$$

Substitute numerical values and evaluate ΔP:

$$\Delta P = \frac{8(0.8\,\text{Pa}\cdot\text{s})(50\,\text{km})}{\pi(0.279\,\text{m})^4}(0.500\text{m}^3/\text{s})$$
$$= 8.41\times10^6\ \text{Pa}$$
$$= 8.41\times10^6\ \text{Pa}\times\frac{1\,\text{atm}}{1.01325\times10^5\ \text{Pa}}$$
$$= 83.0\,\text{atm}$$

This pressure is too large to maintain in the pipe.

Evaluate ΔP for a pipe of 50 cm radius:

$$\Delta P = \frac{8(0.8\,\text{Pa}\cdot\text{s})(50\,\text{km})}{\pi(0.50\,\text{m})^4}(0.500\,\text{m}^3/\text{s})$$
$$= 8.15\times10^5\ \text{Pa}$$
$$= 8.15\times10^5\ \text{Pa}\times\frac{1\,\text{atm}}{1.01325\times10^5\ \text{Pa}}$$
$$= 8.04\,\text{atm}$$

1 m is a reasonable diameter for the pipeline.

84 ••

Picture the Problem We'll measure the height of the liquid–air interfaces relative to the centerline of the pipe. We can use the definition of the volume flow rate in a pipe to find the speed of the water at point A and the relationship between the gauge pressures at points A and C to determine the level of the liquid-air interface at A. We can use the continuity equation to express the speed of the water at B in terms of its speed at A and Bernoulli's equation for constant elevation to find the gauge pressure at B. Finally, we can use the relationship between the gauge pressures at points A and B to find the level of the liquid-air interface at B.

Relate the gauge pressure in the pipe at A to the height of the liquid-air interface at A:

$$P_{\text{gauge,A}} = \rho g h_A$$

where h_A is measured from the center of the pipe.

Solve for h_A:

$$h_A = \frac{P_{\text{gauge,A}}}{\rho g}$$

Substitute numerical values and evaluate h_A:

$$h_A = \frac{(1.22\,\text{atm})(1.01\times10^5\ \text{Pa/atm})}{(10^3\ \text{kg/m}^3)(9.81\,\text{m/s}^2)} = \boxed{12.6\,\text{m}}$$

Determine the velocity of the water at A:

$$v_A = \frac{I_V}{A_A} = \frac{0.8\times10^{-3}\ \text{m}^3/\text{s}}{\frac{\pi}{4}(0.02\,\text{m})^2} = 2.55\,\text{m/s}$$

Apply Bernoulli's equation for constant elevation to relate P_B and P_A:

$$P_A + \tfrac{1}{2}\rho v_A^2 = P_B + \tfrac{1}{2}\rho v_B^2 \qquad (1)$$

Use the continuity equation to relate v_B and v_A:

$$A_A v_A = A_B v_B$$

Solve for v_B:

$$v_B = \frac{A_A}{A_B} v_A = \frac{d_A^2}{d_B^2} v_A = \frac{(2\,\text{cm})^2}{(1\,\text{cm})^2} v_A = 4 v_A$$

Substitute in equation (1) to obtain:

$$P_A + \tfrac{1}{2}\rho v_A^2 = P_B + 8\rho v_A^2$$

Solve for P_B:

$$P_B = P_A - \tfrac{15}{2}\rho v_A^2$$

Substitute numerical values and evaluate P_B:

$$\begin{aligned} P_B &= (2.22\,\text{atm})(1.01\times10^5\,\text{Pa/atm}) \\ &\quad - \tfrac{15}{2}(10^3\,\text{kg/m}^3)(2.55\,\text{m/s})^2 \\ &= 1.75\times10^5\,\text{Pa} \\ &= 1.75\times10^5\,\text{Pa}\times\frac{1\,\text{atm}}{1.01\times10^5\,\text{Pa}} \\ &= 1.733\,\text{atm} \end{aligned}$$

Relate the gauge pressure in the pipe at B to the height of the liquid-air interface at B:

$$P_{\text{gauge,B}} = \rho g h_B$$

Solve for h_B:

$$h_B = \frac{P_{\text{gauge,B}}}{\rho g}$$

Substitute numerical values and evaluate h_B:

$$h_B = \frac{[(1.733-1)\text{atm}]\left(1.01\times10^5\,\frac{\text{Pa}}{\text{atm}}\right)}{(10^3\,\text{kg/m}^3)(9.81\,\text{m/s}^2)} = \boxed{7.55\,\text{m}}$$

85 ••

Picture the Problem We'll measure the height of the liquid–air interfaces relative to the centerline of the pipe. We can use the definition of the volume flow rate in a pipe to find the speed of the water at point A and the relationship between the gauge pressures at points A and C to determine the level of the liquid-air interface at A. We can use the continuity equation to express the speed of the water at B in terms of its speed at A and Bernoulli's equation for constant elevation to find the gauge pressure at B. Finally, we can use the relationship between the gauge pressures at points A and B to find the level of the liquid-air interface at B.

Relate the gauge pressure in the pipe at A to the height of the liquid-air interface at A:

$$P_{\text{gauge,A}} = \rho g h_A$$

where h_A is measured from the center of the pipe.

Solve for h_A:

$$h_A = \frac{P_{\text{gauge,A}}}{\rho g}$$

Substitute numerical values and evaluate h_A:

$$h_A = \frac{(1.22\,\text{atm})(1.01\times10^5\ \text{Pa/atm})}{(10^3\ \text{kg/m}^3)(9.81\,\text{m/s}^2)} = \boxed{12.6\,\text{m}}$$

Determine the velocity of the water at A:

$$v_A = \frac{I_V}{A_A} = \frac{0.6\times10^{-3}\ \text{m}^3/\text{s}}{\frac{\pi}{4}(0.02\,\text{m})^2} = 1.91\,\text{m/s}$$

Use the continuity equation to relate v_B and v_A:

$$A_A v_A = A_B v_B$$

Solve for v_B:

$$v_B = \frac{A_A}{A_B}v_A = \frac{d_A^2}{d_B^2}v_A = \frac{(2\,\text{cm})^2}{(1\,\text{cm})^2}v_A = 4v_A$$

Apply Bernoulli's equation for constant elevation to relate P_B and P_A:

$$P_A + \tfrac{1}{2}\rho v_A^2 = P_B + \tfrac{1}{2}\rho v_B^2 \qquad (1)$$

Substitute in equation (1) to obtain:

$$P_A + \tfrac{1}{2}\rho v_A^2 = P_B + 8\rho v_A^2$$

Solve for P_B:

$$P_B = P_A - \tfrac{15}{2}\rho v_A^2$$

Substitute numerical values and evaluate P_B:

$$\begin{aligned} P_B &= (2.22\,\text{atm})(1.01\times10^5\ \text{Pa/atm}) \\ &\quad - \tfrac{15}{2}(10^3\ \text{kg/m}^3)(1.91\,\text{m/s})^2 \\ &= 1.969\times10^5\ \text{Pa} \\ &= 1.969\times10^5\ \text{Pa}\times\frac{1\,\text{atm}}{1.01\times10^5\ \text{Pa}} \\ &= 1.95\,\text{atm} \end{aligned}$$

Relate the gauge pressure in the pipe at B to the height of the liquid-air interface at B:

$$P_{\text{gauge,B}} = \rho g h_B$$

Solve for h_B:

$$h_B = \frac{P_{\text{gauge,B}}}{\rho g}$$

Substitute numerical values and evaluate h_B:

$$h_B = \frac{[(1.95-1)\text{atm}]\left(1.01\times10^5\,\frac{\text{Pa}}{\text{atm}}\right)}{(10^3\text{ kg/m}^3)(9.81\text{ m/s}^2)} = \boxed{9.78\text{ m}}$$

***86 ••**

Picture the Problem Because it is not given, we'll neglect the difference in height between the centers of the pipes at A and B. We can use the definition of the volume flow rate to find the speed of the water at A and Bernoulli's equation for constant elevation to find its speed at B. Once we know the speed of the water at B, we can use the equation of continuity to find the diameter of the constriction at B.

Use the definition of the volume flow rate to find v_A:

$$v_A = \frac{I_V}{A_A} = \frac{0.5\times10^{-3}\text{ m}^3/\text{s}}{\frac{\pi}{4}(0.02\text{ m})^2} = 1.59\text{ m/s}$$

Use Bernoulli's equation for constant elevation to relate the pressures and velocities at A and B:

$$P_B + \tfrac{1}{2}\rho v_B^2 = P_A + \tfrac{1}{2}\rho v_A^2$$

Solve for v_B^2:

$$v_B^2 = \frac{2(P_A - P_B)}{\rho} + v_A^2$$

Substitute numerical values and evaluate v_B^2:

$$v_B^2 = \frac{2[(1.187-0.1)\text{atm}(1.01\times10^5\text{ Pa/atm})]}{10^3\text{ kg/m}^3} + (1.59\text{ m/s})^2 = 222\text{ m}^2/\text{s}^2$$

Using the continuity equation, relate the volume flow rate to the radius at B:

$$I_V = A_B v_B = \pi r_B^2 v_B$$

Solve for and evaluate r_B:

$$r_B = \sqrt{\frac{I_V}{\pi v_B}} = \sqrt{\frac{0.5\times10^{-3}\text{ m}^3/\text{s}}{\pi(14.9\text{ m/s})}} = 3.27\text{ mm}$$

and

$$d_B = 2r_B = \boxed{6.54\text{ mm}}$$

87 ••

Picture the Problem Let *V*′ represent the volume of the buoy that is submerged and *h*′ the height of the submerged portion of the cylinder. We can find the fraction of the cylinder's volume that is submerged by applying the condition for translational equilibrium to the buoy and using Archimedes' principle. When the buoy is submerged it is in equilibrium under the influence of the tension *T* in the cable, the buoyant force due to the displaced water, and its weight. When the cable breaks, the net force acting on the buoy will accelerate it and we can use Newton's 2nd law to find its acceleration.

(*a*) Apply $\sum F_y = 0$ to the cylinder:

$$B - w = 0$$

Using Archimedes' principle and the definition of weight, substitute for *B* and *w*:

$$\rho_{sw} V' g - mg = 0$$

or

$$\rho_{sw} h' A g - mg = 0$$

where *A* is the cross-sectional area of the buoy.

Solve for and evaluate *h*′:

$$h' = \frac{m}{\rho_{sw} A}$$

Substitute numerical values and evaluate *h*′:

$$h' = \frac{600\,\text{kg}}{\left(1.025\times10^3\,\text{kg/m}^3\right)\frac{\pi}{4}\left(0.9\,\text{m}\right)^2} = 0.920\,\text{m}$$

Use *h*′ to find the height *h* of the buoy:

$$h - h' = 2.6\,\text{m} - 0.920\,\text{m} = \boxed{1.68\,\text{m}}$$

Express the fraction of the volume of the cylinder that is above water:

$$\frac{V - V'}{V} = 1 - \frac{V'}{V} = 1 - \frac{\frac{\pi}{4} d^2 h'}{\frac{\pi}{4} d^2 h} = 1 - \frac{h'}{h}$$

Substitute numerical values to obtain:

$$\frac{V - V'}{V} = 1 - \frac{0.920\,\text{m}}{2.6\,\text{m}} = \boxed{64.6\%}$$

(*b*) Apply $\sum F_y = 0$ to the submerged buoy:

$$B - T - w = 0$$

Solve for T and substitute for B and w to obtain:

$$T = B - w = \rho_{sw} V g - mg = (\rho_{sw} V - m)g$$

Substitute numerical values and evaluate T:

$$T = \left[\left(1.025\times10^3\ \text{kg/m}^3\right)\frac{\pi}{4}(0.9\ \text{m})^2(2.6\ \text{m}) - 600\ \text{kg}\right]\left(9.81\ \text{m/s}^2\right) = \boxed{10.7\ \text{kN}}$$

(*c*) Apply $\sum F_y = 0$ to the buoy:

$$B - w = ma$$

Substitute for $B - w$ and solve for a to obtain:

$$a = \frac{B-w}{m} = \frac{T}{m}$$

Substitute numerical values and evaluate a:

$$a = \frac{10.75\ \text{kN}}{600\ \text{kg}} = \boxed{17.9\ \text{m/s}^2}$$

88 ••

Picture the Problem Because the floating object is in equilibrium under the influence of the buoyant force acting on it and its weight; we can apply the condition for translational equilibrium to relate B and w. Let Δh represent the change in elevation of the liquid level and V_f the volume of the displaced fluid.

Apply $\sum F_y = 0$ to the floating object:

$$B - w = 0$$

Using Archimedes' principle and the definition of weight, substitute for B and w:

$$\rho_0 g V_f - mg = 0$$

The volume of fluid displaced is the sum of the volume displaced in the two vessels:

$$V_f = \Delta V_A + \Delta V_{3A} = A\Delta h + 3A\Delta h = 4A\Delta h$$

Substitute for V_f to obtain:

$$4\rho_0 g A\Delta h - mg = 0$$

Solve for Δh:

$$\Delta h = \boxed{\frac{m}{4A\rho_0}}$$

89 ••

Picture the Problem We can calculate the smallest pressure change ΔP that can be detected from the reading Δh from $\Delta P = \rho g \Delta h$.

Express and evaluate the pressure difference between the two columns of the manometer:

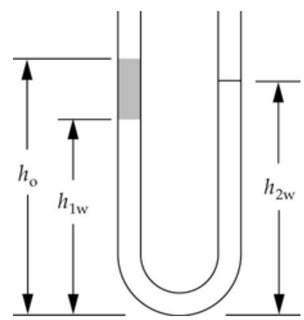
$$\Delta P = \rho g \Delta h = (900\,\text{kg/m}^3)(9.81\,\text{m/s}^2) \times (0.05\times10^{-3}\,\text{m}) = 0.4415\,\text{Pa}$$

Express this pressure in mmHg and μmHg:

$$\Delta P = 0.4415\,\text{Pa} \times \frac{1\,\text{atm}}{1.01325\times10^{5}\,\text{Pa}} \times \frac{760\,\text{mmHg}}{1\,\text{atm}} = \boxed{3.31\times10^{-3}\,\text{mmHg}} = \boxed{3.31\,\mu\text{mHg}}$$

90 ••

Picture the Problem We can use the equality of the pressure at the bottom of the U-tube due to the water on one side and that due to the oil and water on the other to relate the various heights. Let h represent the height of the oil above the water. Then $h_o = h_{1w} + h$.



Using the constancy of the amount of water, express the relationship between h_{1w} and h_{2w}:

$$h_{1w} + h_{2w} = 56\text{ cm}$$

Find the height of the oil-water interface:

$$h_{1w} = 56\,\text{cm} - 34\,\text{cm} = \boxed{22.0\,\text{cm}}$$

Express the equality of the pressure at the bottom of the two arms of the U tube:

$$\rho_w g(34\,\text{cm}) = \rho_w g(22\,\text{cm}) + 0.78\rho_w g h_{oil}$$

Solve for and evaluate h_{oil}:

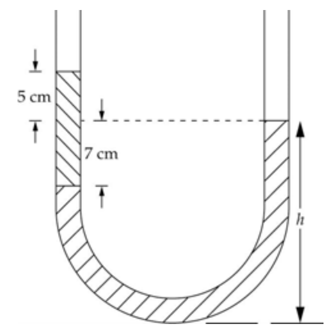
$$h_{oil} = \frac{\rho_w g(34\,\text{cm}) - \rho_w g(22\,\text{cm})}{0.78\rho_w g} = \frac{(34\,\text{cm}) - (22\,\text{cm})}{0.78} = 15.4\,\text{cm}$$

Find the height of the air-oil interface h_o:

$$h_o = 22\text{cm} + 15.4\,\text{cm} = \boxed{37.4\,\text{cm}}$$

91 ••

Picture the Problem Let σ_L represent the specific gravity of the liquid. The specific gravity of the oil is $\sigma_o = 0.8$. We can use the equality of the pressure at the bottom of the U-tube due to the water on one side and that due to the oil and water on the other to relate the various heights.



Express the equality of the pressure at the bottom of the two arms of the U tube:

$$\sigma_L gh = \sigma_L g(h - 7\,\text{cm}) + 0.8\sigma_w g(12\,\text{cm})$$

Solve for and evaluate σ_L:

$$\sigma_L = \frac{0.8\sigma_w(12\,\text{cm})}{7\,\text{cm}} = \frac{0.8(12\,\text{cm})}{7\,\text{cm}} = \boxed{1.37}$$

92 ••

Picture the Problem The block of wood is in translational equilibrium under the influence of the buoyant force due to the displaced water acting on it and on the lead block, its weight, and the weight of the lead block. We can use a condition for translational equilibrium and Archimedes' principle to obtain a relationship between the mass of the lead block and the densities of water, wood, and lead and the mass of the wood block.

Apply $\sum F_y = 0$ to the block of wood:

$$B_{wood} + B_{Pb} - m_{wood}g - m_{Pb}g = 0$$

Use Archimedes' principle to express the buoyant force on the block of wood:

$$B_{wood} = \rho_w V_{wood} g$$

Use Archimedes' principle to

$$B_{Pb} = \rho_w V_{Pb} g$$

express the buoyant force on the lead block:

Substitute and simplify to obtain:

$$\rho_w V_{wood} + \rho_w V_{Pb} - m_{wood} - m_{Pb} = 0$$

Express the volume of the wood block in terms of its density and mass:

$$V_{wood} = \frac{m_{wood}}{\rho_{wood}}$$

Express the volume of the lead block in terms of its density and mass:

$$V_{Pb} = \frac{m_{Pb}}{\rho_{Pb}}$$

Substitute for V_{wood} and V_{Pb}:

$$\rho_w \frac{m_{wood}}{\rho_{wood}} + \rho_w \frac{m_{Pb}}{\rho_{Pb}} - m_{wood} - m_{Pb} = 0$$

Solve for m_{Pb}:

$$m_{Pb} = \frac{\left(\frac{\rho_w}{\rho_{wood}} - 1\right) m_{wood}}{1 - \frac{\rho_w}{\rho_{Pb}}}$$

Substitute numerical values and evaluate m_{Pb}:

$$m_{Pb} = \frac{\left(\frac{1}{0.7} - 1\right)(0.5\,\text{kg})}{1 - \frac{1}{11.3}} = \boxed{0.235\,\text{kg}}$$

***93 ••**

Picture the Problem Because the balloon is in equilibrium under the influence of the buoyant force exerted by the air, the weight of its basket and load *w*, the weight of the skin of the balloon, and the weight of the helium. Choose upward to be the positive *y* direction and apply the condition for translational equilibrium to relate these forces. Archimedes' principle relates the buoyant force on the balloon to the density of the air it displaces and the volume of the balloon.

(*a*) Apply $\sum F_y = 0$ to the balloon:

$$B - m_{skin}g - m_{He}g - w = 0$$

Letting *V* represent the volume of the balloon, use Archimedes' principle to express the buoyant force:

$$\rho_{air}Vg - m_{skin}g - m_{He}g - w = 0$$

Substitute for m_{He}:

$$\rho_{air}Vg - m_{skin}g - \rho_{He}Vg - w = 0$$

Solve for V:

$$V = \frac{m_{\text{skin}} g + w}{(\rho_{\text{air}} - \rho_{\text{He}})g}$$

Substitute numerical values and evaluate V:

$$V = \frac{(1.5\,\text{kg})(9.81\,\text{m/s}^2) + 750\,\text{N}}{(1.293 - 0.1786)(\text{kg/m}^3)(9.81\,\text{m/s}^2)} = \boxed{70.0\,\text{m}^3}$$

(*b*) Apply $\sum F_y = ma$ to the balloon:

$$B - m_{\text{tot}} g = m_{\text{tot}} a$$

Solve for a:

$$a = \frac{B}{m_{\text{tot}}} - g$$

Assuming that the mass of the skin has not changed and letting V' represent the doubled volume of the balloon, express m_{tot}:

$$m_{\text{tot}} = m_{\text{load}} + m_{\text{He}} + m_{\text{skin}} = \frac{w_{\text{load}}}{g} + \rho_{\text{He}} V' + m_{\text{skin}}$$

Substitute numerical values and evaluate m_{tot}:

$$m_{\text{tot}} = \frac{900\,\text{N}}{9.81\,\text{m/s}^2} + (0.1786\,\text{kg/m}^3)(140\,\text{m}^3) + 1.5\,\text{kg} = 118\,\text{kg}$$

Express the buoyant force acting on the balloon:

$$B = w_{\text{displaced fluid}} = \rho_{\text{air}} V' g$$

Substitute numerical values and evaluate B:

$$B = (1.293\,\text{kg/m}^3)(140\,\text{m}^3)(9.81\,\text{m/s}^2) = 1.78\,\text{kN}$$

Substitute and evaluate a:

$$a = \frac{1.78\,\text{kN}}{118\,\text{kg}} - 9.81\,\text{m/s}^2 = \boxed{5.27\,\text{m/s}^2}$$

94 ••

Picture the Problem When the hollow sphere is completely submerged but floating, it is in translational equilibrium under the influence of a buoyant force and its weight. The buoyant force is given by Archimedes' principle and the weight of the sphere is the sum of the weights of the hollow sphere and the material filling its center.

Apply $\sum F_y = 0$ to the hollow sphere:

$$B - w = 0$$

Express the buoyant force acting on the hollow sphere:

$$B = 2\rho_0 V_{\text{sphere}} g = 2\rho_0\left[\tfrac{4}{3}\pi(2R)^3\right]g = \tfrac{64}{3}\rho_0\pi R^3 g$$

Express the weight of the sphere when it's hollow is filled with a material of density ρ':

$$w = \rho_0 V_{\text{hollow sphere}} g + \rho' V_{\text{hollow}} g = \rho_0\left[\tfrac{4}{3}\pi\left\{(2R)^3 - R^3\right\}\right]g + \rho'\left[\tfrac{4}{3}\pi R^3\right]g = \tfrac{28}{3}\rho_0\pi R^3 g + \tfrac{4}{3}\rho'\pi R^3 g$$

Substitute to obtain:

$$\tfrac{64}{3}\rho_0\pi R^3 g - \tfrac{28}{3}\rho_0\pi R^3 g - \tfrac{4}{3}\rho'\pi R^3 g = 0$$

Solve for ρ':

$$\rho' = \boxed{9\rho_0}$$

***95 ••**

Picture the Problem We can differentiate the function $P(h)$ to show that it satisfies the differential equation $dP/P = -C\,dh$ and in part (*b*) we can use the approximation $e^{-x} \approx 1 - x$ and $\Delta h << h_0$ to establish the given result.

(*a*) Differentiate $P(h) = P_0 e^{-Ch}$:

$$\frac{dP}{dh} = -CP_0 e^{-Ch} = -CP$$

Separate variables to obtain:

$$\boxed{\frac{dP}{P} = -C\,dh}$$

(*b*) Express $P(h + \Delta h)$:

$$P(h+\Delta h) = P_0 e^{-C(h+\Delta h)} = P_0 e^{-Ch} e^{-C\Delta h} = P(h) e^{-C\Delta h}$$

For $\Delta h << h_0$:

$$\frac{\Delta h}{h_0} << 1$$

Let $h_0 = 1/C$. Then:

$$C\Delta h << 1$$

and

$$e^{-C\Delta h} \approx 1 - C\Delta h = 1 - \frac{\Delta h}{h_0}$$

Substitute to obtain:

$$P(h+\Delta h) = \boxed{P(h)\left(1 - \frac{\Delta h}{h_0}\right)}$$

(*c*) Take the logarithm of both sides of the function $P(h)$:

$$\ln P = \ln P_0 e^{-Ch} = \ln P_0 + \ln e^{-Ch} = \ln P_0 - Ch$$

Solve for C:

$$C = \frac{1}{h}\ln\left(\frac{P_0}{P}\right)$$

Substitute numerical values and evaluate C:

$$C = \frac{1}{5.5\,\text{km}}\ln\left(\frac{P_0}{\frac{1}{2}P_0}\right) = \frac{1}{5.5\,\text{km}}\ln 2 = \boxed{0.126\,\text{km}^{-1}}$$

96 ••

Picture the Problem Let V represent the volume of the submarine and V' the volume of seawater it displaces when it is on the surface. The submarine is in equilibrium in both parts of the problem. Hence we can apply the condition for translational equilibrium (neutral buoyancy) to the submarine to relate its weight to the buoyant force acting on it. We'll also use Archimedes' principle to connect the buoyant forces to the volume of seawater the submarine displaces. Let upward be the positive y direction.

(*a*) Express f, the fraction of the submarine's volume above the surface when the tanks are filled with air:

$$f = \frac{V - V'}{V} = 1 - \frac{V'}{V} \quad (1)$$

Apply $\sum F_y = 0$ to the submarine when its tanks are full of air:

$$B - w = 0$$

Use Archimedes' principle to express the buoyant force on the submarine in terms of the volume of the displaced water:

$$B = \rho_{sw} V' g$$

Substitute and solve for V':

$$V' = \frac{m}{\rho_{sw}}$$

Substitute in equation (1) to obtain:

$$f = 1 - \frac{m}{\rho_{sw} V}$$

Substitute numerical values and evaluate *f*:

$$f = 1 - \frac{2.4\times10^{6}\ \text{kg}}{\left(1.025\times10^{3}\ \text{kg/m}^{3}\right)\left(2.4\times10^{3}\ \text{m}^{3}\right)} = 2.44\times10^{-2} = \boxed{2.44\%}$$

(*b*) Express the volume of seawater in terms of its mass and density:

$$V_{sw} = \frac{m_{sw}}{\rho_{sw}} \qquad (2)$$

Apply $\sum F_y = 0$, the condition for neutral buoyancy, to the submarine:

$$B - w_{sub} - w_{sw} = 0$$

Use Archimedes' principle to express the buoyant force on the submarine in terms of the volume of the displaced water:

$$B = \rho_{sw} V g$$

Substitute to obtain:

$$\rho_{sw} V g - m_{sub} g - m_{sw} g = 0$$

Solve for m_{sw}:

$$m_{sw} = \rho_{sw} V - m_{sub}$$

Substitute for V_{sw} in equation (2) to obtain:

$$V_{sw} = \frac{\rho_{sw} V - m_{sub}}{\rho_{sw}} = V - \frac{m_{sub}}{\rho_{sw}}$$

Substitute numerical values and evaluate V_{sw}:

$$V_{sw} = 2.4\times10^{3}\ \text{m}^{3} - \frac{2.4\times10^{6}\ \text{kg}}{1.025\times10^{3}\ \text{kg/m}^{3}} = \boxed{58.5\ \text{m}^{3}}$$

97 ••

Picture the Problem While the loaded crate is under the surface, it is in equilibrium under the influence of the tension in the cable, the buoyant force acting on the gold, and the gravitational force acting on the gold. The empty crate has neutral buoyancy. When the crate is out of the water, the buoyant force of the air is negligible and the tension in the cable is the sum of the weights of the crate, the gold bullion, and the seawater.

(*a*) Apply $\sum F_y = 0$ to the crate while it is below the surface:

$$T + B_{Au} - w_{Au} = 0$$

Solve for the tension in the cable:

$$T = w_{Au} - B_{Au}$$

Using Archimedes' principle, relate the buoyant force acting on the gold

$$B_{Au} = \rho_{sw} V_{Au} g$$

to its density and volume:

Substitute for B_{Au} and simplify to obtain: $T = (\rho_{\text{Au}} - \rho_{\text{sw}})V_{\text{Au}}g$

Substitute numerical values and evaluate T:

$$T = [(19.3\times10^3\ \text{kg/m}^3) - (1.025\times10^3\ \text{kg/m}^3)](0.36)(1.4\,\text{m})(0.75\,\text{m})(0.5\,\text{m})(9.81\,\text{m/s}^2) = \boxed{33.9\,\text{kN}}$$

(*b*) 1. Apply $\sum F_y = 0$ to the crate while it is being lifted to the deck of the ship with none of the seawater leaking out: $T - w_{\text{Au}} - w_{\text{crate}} - w_{\text{sw}} = 0$

Substitute for the weights of the gold, crate, and seawater and solve for the tension in the cable and express:

$$\begin{aligned} T &= w_{\text{Au}} + w_{\text{crate}} + w_{\text{sw}} \\ &= \rho_{\text{Au}}V_{\text{Au}}g + m_{\text{crate}}g + \rho_{\text{sw}}V_{\text{sw}}g \\ &= (\rho_{\text{Au}}V_{\text{Au}} + m_{\text{crate}} + \rho_{\text{sw}}V_{\text{sw}})g \end{aligned}$$

Substitute numerical values and evaluate T:

$$\begin{aligned} T &= [(19.3\times10^3\ \text{kg/m}^3)(0.36)(1.4\,\text{m})(0.75\,\text{m})(0.5\,\text{m}) + 32\,\text{kg} + (1.025\times10^3\ \text{kg/m}^3) \\ &\quad\times(0.64)(1.4\,\text{m})(0.75\,\text{m})(0.5\,\text{m})](9.81\,\text{m/s}^2) \\ &= \boxed{39.8\,\text{kN}} \end{aligned}$$

2. With the seawater term missing, the expression for the tension is:

$$\begin{aligned} T &= w_{\text{Au}} + w_{\text{crate}} \\ &= \rho_{\text{Au}}V_{\text{Au}}g + m_{\text{crate}}g \\ &= (\rho_{\text{Au}}V_{\text{Au}} + m_{\text{crate}})g \end{aligned}$$

Substitute numerical values and evaluate T:

$$T = [(19.3\times10^3\ \text{kg/m}^3)(0.36)(1.4\,\text{m})(0.75\,\text{m})(0.5\,\text{m}) + 32\,\text{kg}](9.81\,\text{m/s}^2) = \boxed{36.1\,\text{kN}}$$

98 •••

Picture the Problem In the three situations described in the problem the hydrometer will be in equilibrium under the influence of its weight and the buoyant force exerted by the liquids. We can use Archimedes' principle to relate the buoyant force acting on the hydrometer to the density of the liquid in which it is floating and to its weight.

(*a*) Find the volume of the bulb:

$$V_{\text{bulb}} = \tfrac{1}{6}\pi d^3 = \tfrac{1}{6}\pi(2.4\,\text{cm})^3 = 7.238\,\text{cm}^3$$

Find the volume of the tube:

$$V_{\text{tube}} = \tfrac{1}{4}\pi d^2 L = \tfrac{1}{4}\pi(0.75\,\text{cm})^2(20\,\text{cm}) = 8.836\,\text{cm}^2$$

Apply $\sum F_y = 0$ to the hydrometer just floating in the liquid:

$$B - w_{\text{hyd}} - m_{\text{Pb}}g = 0$$

Substitute for B and w_{glass}:

$$\rho_{\text{liq}}V_{\text{hyd}}g - m_{\text{glass}}g - m_{\text{Pb}}g = 0$$

Solve for m_{Pb}:

$$m_{\text{Pb}} = \rho_{\text{liq}}V_{\text{hyd}} - m_{\text{hyd}}$$

Substitute numerical values and evaluate m_{Pb}:

$$m_{\text{Pb}} = 0.78(1\,\text{g/cm}^3) \times (7.238\,\text{cm}^3 + 8.836\,\text{cm}^3) - 7.28\,\text{g} = \boxed{5.26\,\text{g}}$$

(*b*) Letting V represent the volume of the hydrometer that is submerged, apply $\sum F_y = 0$ to the hydrometer just floating in the liquid:

$$\rho_{\text{w}}Vg - mg = 0$$

Solve for V:

$$V = \frac{m}{\rho_{\text{w}}} = \frac{m_{\text{hyd}} + m_{\text{Pb}}}{\rho_{\text{w}}}$$

Substitute numerical values and evaluate V:

$$V = \frac{7.28\,\text{g} + 5.26}{1\,\text{g/cm}^3} = 12.54\,\text{cm}^3$$

Relate the volume of the hydrometer that is submerged to the volume of the bulb and the volume of the tube that is submerged:

$$V = \tfrac{1}{4}\pi\, d_{\text{tube}}^2 h' + V_{\text{bulb}}$$

Solve for h':

$$h' = \frac{V - V_{\text{bulb}}}{\tfrac{1}{4}\pi\, d_{\text{tube}}^2}$$

Substitute numerical values and evaluate h':

$$h' = \frac{12.54\,\text{cm}^3 - 7.238\,\text{cm}^3}{\tfrac{1}{4}\pi(0.75\,\text{cm})^2} = 12.0\,\text{cm}$$

Find the length of the tube that shows above the surface of the water:

$$h = 20\,\text{cm} - h' = 20\,\text{cm} - 12.0\,\text{cm} = \boxed{8.00\,\text{cm}}$$

(*c*) Apply $\sum F_y = 0$ to the hydrometer floating in the liquid of unknown specific gravity:

$$\rho_\text{L} V_\text{L} g - m_\text{hyd} g = 0$$

Solve for the density of the liquid:

$$\rho_\text{L} = \frac{m_\text{hyd}}{V_\text{L}}$$

Express the volume of the displaced liquid:

$$V_\text{L} = V_\text{bulb} + \tfrac{1}{4}\pi d_\text{tube}^2 h'$$

Substitute numerical values and evaluate V_L:

$$V_\text{L} = 7.238\,\text{cm}^3 + \tfrac{1}{4}\pi(0.75\,\text{cm})^2 \times (20\,\text{cm} - 12.2\,\text{cm}) = 10.68\,\text{cm}^3$$

Substitute for V_L and m_hyd and evaluate ρ_L:

$$\rho_\text{L} = \frac{12.54\,\text{g}}{10.68\,\text{cm}^3} = 1.174\,\text{g/cm}^3$$

Express and evaluate the specific gravity of the liquid:

$$\text{specific gravity}_\text{liquid} = \frac{\rho_\text{w}}{\rho_\text{L}} = \boxed{1.17}$$

99 •••

Picture the Problem We can apply Bernoulli's equation to the top of the keg and to the spigot opening to determine the rate at which the root beer exits the tank. Because the area of the spigot is much smaller than that of the keg, we can neglect the velocity of the root beer at the top of the keg. We'll use the continuity equation to obtain an expression for the rate of change of the height of the root beer in the keg as a function of the its height and integrate this function to find *h* as a function of time.

(*a*) Apply Bernoulli's equation to the beer at the top of the keg and at the spigot:

$$P_1 + \rho_\text{beer} gh + \tfrac{1}{2}\rho_\text{beer} v_1^2 = P_2 + \rho_\text{beer} gh_2 + \tfrac{1}{2}\rho_\text{beer} v_2^2$$

or, because $v_1 \approx 0$, $h_2 = 0$, $P_1 = P_2 = P_\text{at}$, and $h_1 = h$,

$$gh = \tfrac{1}{2}v_2^2$$

Solve for v_2:

$$v_2 = \boxed{\sqrt{2gh}}$$

(*b*) Use the continuity equation to relate v_1 and v_2:

$$A_1 v_1 = A_2 v_2$$

Substitute $-dh/dt$ for v_1:

$$-A_1 \frac{dh}{dt} = A_2 v_2$$

Substitute for v_2 and solve for dh/dt to obtain:

$$\frac{dh}{dt} = \boxed{-\frac{A_2}{A_1}\sqrt{2gh}}$$

(*c*) Separate the variables in the differential equation:

$$-\frac{A_1/A_2}{\sqrt{2g}}\frac{dh}{\sqrt{h}} = dt$$

Express the integral from $h' = H$ to h and $t' = 0$ to t:

$$-\frac{A_1/A_2}{\sqrt{2g}}\int_H^h \frac{dh'}{\sqrt{h'}} = \int_0^t dt'$$

Evaluate the integral to obtain:

$$-\frac{A_1/A_2}{\sqrt{2g}}\left(\sqrt{H}-\sqrt{h}\right) = t$$

Solve for h:

$$h = \boxed{\left(\sqrt{H} - \frac{A_2}{2A_1}\sqrt{2g}\,t\right)^2}$$

(*d*) Solve $h(t)$ for the time-to-drain t':

$$t' = \frac{A_1}{A_2}\sqrt{\frac{2H}{g}}$$

Substitute numerical values and evaluate t'

$$t' = \frac{A_1}{10^{-4}A_1}\sqrt{\frac{2(2\,\text{m})}{9.81\,\text{m/s}^2}} = 6.39\times10^3\ \text{s}$$

$$= \boxed{1\,\text{h}\ 46\ \text{min}}$$

Chapter 14
Oscillations

Conceptual Problems

1 •

Determine the Concept The acceleration of an oscillator of amplitude A and frequency f is zero when it is passing through its equilibrium position and is a maximum when it is at its turning points.

When $v = v_{max}$: $a = \boxed{0}$

When $x = x_{max}$: $a = \omega^2 A = \boxed{4\pi^2 f^2 A}$

2 •

Determine the Concept The condition for simple harmonic motion is that there be a linear restoring force; i.e., that $F = -kx$. Thus, the acceleration and displacement (when they are not zero) are always oppositely directed. v and a can be in the same direction, as can v and x.

3 •

(*a*) False. In simple harmonic motion, the period is independent of the amplitude.

(*b*) True. In simple harmonic motion, the frequency is the reciprocal of the period which, in turn, is independent of the amplitude.

(*c*) True. The condition that the acceleration of a particle is proportional to the displacement and oppositely directed is equivalent to requiring that there be a linear restoring force; i.e., $F = -kx \Leftrightarrow ma = -kx$ or $a = -(k/m)x$.

***4 •**

Determine the Concept The energy of a simple harmonic oscillator varies as the square of the amplitude of its motion. Hence, tripling the amplitude increases the energy by a factor of 9.

5 ••

Picture the Problem The total energy of an object undergoing simple harmonic motion is given by $E_{tot} = \frac{1}{2}kA^2$, where k is the stiffness constant and A is the amplitude of the motion. The potential energy of the oscillator when it is a distance x from its equilibrium position is $U(x) = \frac{1}{2}kx^2$.

Express the ratio of the potential energy of the object when it is 2 cm from the equilibrium position to its total energy:

$$\frac{U(x)}{E_{tot}}=\frac{\frac{1}{2}kx^2}{\frac{1}{2}kA^2}=\frac{x^2}{A^2}$$

Evaluate this ratio for $x = 2$ cm and $A = 4$ cm:

$$\frac{U(2\,\text{cm})}{E_{tot}}=\frac{(2\,\text{cm})^2}{(4\,\text{cm})^2}=\frac{1}{4}$$

$$\frac{U(2\,\text{cm})}{E_{tot}}=\frac{(2\,\text{cm})^2}{(4\,\text{cm})^2}=\frac{1}{4}$$

and $\boxed{(a)\text{ is correct.}}$

6 •

(*a*) True. The factors determining the period of the object, i.e., its mass and the spring constant, are independent of the oscillator's orientation.

(*b*) True. The factors determining the maximum speed of the object, i.e., its amplitude and angular frequency, are independent of the oscillator's orientation.

7 •

False. In order for a simple pendulum to execute simple harmonic motion, the restoring force must be linear. This condition is satisfied, at least approximately, for small initial angular displacements.

8 •

True. In order for a simple pendulum to execute periodic motion, the restoring force must be linear. This condition is satisfied for any initial angular displacement.

***9** ••

Determine the Concept Assume that the first cart is given an initial velocity *v* by the blow. After the initial blow, there are no external forces acting on the carts, so their center of mass moves at a constant velocity *v*/2. The two carts will oscillate about their center of mass in simple harmonic motion where the amplitude of their velocity is *v*/2. Therefore, when one cart has velocity *v*/2 with respect to the center of mass, the other will have velocity –*v*/2. The velocity with respect to the laboratory frame of reference will be +*v* and 0, respectively. Half a period later, the situation is reversed; one cart will move as the other stops, and vice-versa.

***10** ••

Determine the Concept The period of a simple pendulum depends on the reciprocal of the length of the pendulum. Increasing the length of the pendulum will decrease its period and the clock would run slow.

11 •

True. The mechanical energy of a damped, undriven oscillator varies with time according to $E = E_0 e^{-t/\tau}$ where E_0 is the oscillator's energy at $t = 0$ and τ is the time constant.

12 •

(*a*) True. The amplitude of the motion of a driven oscillator depends on the driving (ω) and natural (ω_0) frequencies according to $A = F_0 \big/ \sqrt{m^2\left(\omega_0^2 - \omega^2\right)^2 + b^2\omega^2}$. When $\omega = \omega_0$, the amplitude of the motion is a maximum and is given by $A = F_0 \big/ \sqrt{b^2\omega^2}$.

(*b*) True. The width of the resonance curve ($\Delta\omega$) depends on the Q value according to $\Delta\omega/\omega_0 = 1/Q$. Thus when Q is large, $\Delta\omega$ is small and the resonance is sharp.

13 •

Determine the Concept Examples of driven oscillators include the pendulum of a clock, a bowed violin string, and the membrane of any loudspeaker.

14 •

Determine the Concept The shattering of a crystal wineglass is a consequence of the glass being driven at or near its resonant frequency. $\boxed{(a)\text{ is correct.}}$

***15** •

Determine the Concept We can use the expression for the frequency of a spring-and-mass oscillator to determine the effect of the mass of the spring.

If m represents the mass of the object attached to the spring in a spring-and-mass oscillator, the frequency is given by:

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{m}}$$

If the mass of the spring is taken into account, the effective mass is greater than the mass of the object alone.

$$f' = \frac{1}{2\pi}\sqrt{\frac{k}{m_{\text{eff}}}}$$

Divide the second of these equations by the first and simplify to obtain:

$$\frac{f'}{f} = \frac{\frac{1}{2\pi}\sqrt{\frac{k}{m_{\text{eff}}}}}{\frac{1}{2\pi}\sqrt{\frac{k}{m}}} = \sqrt{\frac{m}{m_{\text{eff}}}}$$

Solve for f':

$$f' = f\sqrt{\frac{m}{m_{\text{eff}}}}$$

Because f' varies inversely with the square root of m, taking into account the effective mass of the spring predicts that the frequency will be reduced.

16 ••

Determine the Concept The period of the lamp varies inversely with the square root of the effective value of the local gravitational field.

1. greater than T_0 when — B. the train rounds a curve of radius R with speed v.

2. less than T_0 when — D. the train goes over the crest of a hill of radius of curvature R with constant speed.

3. equal to T_0 when — A. the train moves horizontally with constant velocity.

C. the train climbs a hill of inclination θ at constant speed.

17 ••

Picture the Problem We can use $f = \frac{1}{2\pi}\sqrt{\frac{k}{M}}$ to express the frequencies of the two mass-spring systems in terms of their masses. Dividing one of the equations by the other will allow us to express M_A in terms of M_B.

Express the frequency of mass-spring system A as a function of its mass:

$$f_A = \frac{1}{2\pi}\sqrt{\frac{k}{M_A}}$$

Express the frequency of mass-spring system B as a function of its mass:

$$f_B = \frac{1}{2\pi}\sqrt{\frac{k}{M_B}}$$

Divide the second of these equations by the first to obtain:

$$\frac{f_B}{f_A} = \sqrt{\frac{M_A}{M_B}}$$

Solve for M_A:

$$M_A = \left(\frac{f_B}{f_A}\right)^2 M_B = \left(\frac{f_B}{2f_B}\right)^2 M_B = \tfrac{1}{4}M_B$$

and $\boxed{(d)\text{ is correct.}}$

18 ••

Picture the Problem We can relate the energies of the two mass-spring systems through either $E = \frac{1}{2}kA^2$ or $E = \frac{1}{2}M\omega^2 A^2$ and investigate the relationship between their amplitudes by equating the expressions, substituting for M_A, and expressing A_A in terms of A_B.

Express the energy of mass-spring system A:

$$E_A = \frac{1}{2}k_A A_A^2 = \frac{1}{2}M_A\omega_A^2 A_A^2$$

Express the energy of mass-spring system B:

$$E_B = \frac{1}{2}k_B A_B^2 = \frac{1}{2}M_B\omega_B^2 A_B^2$$

Divide the first of these equations by the second to obtain:

$$\frac{E_A}{E_B} = 1 = \frac{\frac{1}{2}M_A\omega_A^2 A_A^2}{\frac{1}{2}M_B\omega_B^2 A_B^2}$$

Substitute for M_A and simplify:

$$1 = \frac{2M_B\omega_A^2 A_A^2}{M_B\omega_B^2 A_B^2} = \frac{2\omega_A^2 A_A^2}{\omega_B^2 A_B^2}$$

Solve for A_A:

$$A_A = \frac{\omega_B}{\sqrt{2}\omega_A}A_B$$

Without knowing how ω_A and ω_B, or k_A and k_B, are related, we cannot simplify this expression further. $\boxed{(d)\text{ is correct.}}$

19 ••

Picture the Problem We can express the energy of each system using $E = \frac{1}{2}kA^2$ and, because the energies are equal, equate them and solve for A_A.

Express the energy of mass-spring system A in terms of the amplitude of its motion:

$$E_A = \frac{1}{2}k_A A_A^2$$

Express the energy of mass-spring system B in terms of the amplitude of its motion:

$$E_B = \frac{1}{2}k_B A_B^2$$

Because the energies of the two systems are equal we can equate them to obtain:

$$\tfrac{1}{2}k_A A_A^2 = \tfrac{1}{2}k_B A_B^2$$

Solve for A_A:

$$A_A = \sqrt{\frac{k_B}{k_A}}A_B$$

Substitute for k_A and simplify to obtain:

$$A_A = \sqrt{\frac{k_B}{2k_B}}A_B = \frac{A_B}{\sqrt{2}}$$

and $\boxed{(b)\text{ is correct.}}$

20 ••

Picture the Problem The period of a simple pendulum is independent of the mass of its bob and is given by $T = 2\pi\sqrt{L/g}$.

Express the period of pendulum A:

$$T_A = 2\pi\sqrt{\frac{L_A}{g}}$$

Express the period of pendulum B:

$$T_B = 2\pi\sqrt{\frac{L_B}{g}}$$

Divide the first of these equations by the second and solve for L_A/L_B:

$$\frac{L_A}{L_B} = \left(\frac{T_A}{T_B}\right)^2$$

Substitute for T_A and solve for L_B to obtain:

$$L_A = \left(\frac{2T_B}{T_B}\right)^2 L_B = 4L_B$$

and $\boxed{(c)\text{ is correct.}}$

Estimation and Approximation

21 ••

Picture the Problem The Q factor for this system is related to the decay constant τ through $Q = \omega_0\tau = 2\pi\tau/T$ and the amplitude of the child's damped motion varies with time according to $A = A_0 e^{-t/2\tau}$. We can set the ratio of two displacements separated by eight periods equal to $1/e$ to determine τ in terms of T.

Express Q as a function of τ:

$$q = \omega_0\tau = \frac{2\pi\tau}{T} \qquad (1)$$

The amplitude of the oscillations varies with time according to:

$$A = A_0 e^{-t/2\tau}$$

The amplitude after eight periods is:

$$A_8 = A_0 e^{-(t+8T)/2\tau}$$

Express and simplify the ratio A_8/A:

$$\frac{A_8}{A} = \frac{A_0 e^{-(t+8T)/2\tau}}{A_0 e^{-t/2\tau}} = e^{-4T/\tau}$$

Set this ratio equal to $1/e$ and solve for τ:

$$e^{-4T/\tau} = e^{-1} \Rightarrow \tau = 4T$$

Substitute in equation (1) and evaluate Q:

$$Q = \frac{2\pi(4T)}{T} = \boxed{8\pi}$$

***22 ••**

Picture the Problem Assume that an average length for an arm is about 0.8 m, and that it can be treated as a uniform stick, pivoted at one end. We can use the expression for the period of a physical pendulum to derive an expression for the period of the swinging arm. When carrying a heavy briefcase, the mass is concentrated mostly at the end of the pivot (i.e., in the briefcase), so we can treat the arm-plus-briefcase as a simple pendulum.

(*a*) Express the period of a uniform rod pivoted at one end:

$$T = 2\pi\sqrt{\frac{I}{MgD}}$$

where I is the moment of inertia of the stick about an axis through one end, M is the mass of the stick, and D (= $L/2$) is the distance from the end of the stick to its center of mass.

Express the moment of inertia of the stick with respect to an axis through its end:

$$I = \tfrac{1}{3}ML^2$$

Substitute the values for I and D to find T:

$$T = 2\pi\sqrt{\frac{\frac{1}{3}ML^2}{Mg\left(\frac{1}{2}L\right)}} = 2\pi\sqrt{\frac{2L}{3g}}$$

Substitute numerical values and evaluate T:

$$T = 2\pi\sqrt{\frac{2(0.8\,\text{m})}{3(9.81\,\text{m/s}^2)}} = \boxed{1.47\,\text{s}}$$

(*b*) Express the period of a simple pendulum:

$$T' = 2\pi\sqrt{\frac{L'}{g}}$$

where L' is slightly longer than the arm length due to the size of the briefcase.

Assuming $L' = 1$ m, evaluate the period of the simple pendulum:

$$T' = 2\pi\sqrt{\frac{1\,\text{m}}{9.81\,\text{m/s}^2}} = \boxed{2.01\,\text{s}}$$

$$\boxed{\text{From observation of people as they walk, these estimates seem reasonable.}}$$

Simple Harmonic Motion

23 •

Picture the Problem The position of the particle is given by $x = A\cos(\omega t + \delta)$ where A is the amplitude of the motion, ω is the angular frequency, and δ is a phase constant.

(*a*) Use the definition of ω to determine f:

$$f = \frac{\omega}{2\pi} = \frac{6\pi\,\text{s}^{-1}}{2\pi} = \boxed{3.00\,\text{Hz}}$$

(*b*) Evaluate the reciprocal of the frequency:

$$T = \frac{1}{f} = \frac{1}{3.00\,\text{Hz}} = \boxed{0.333\,\text{s}}$$

(*c*) Compare $x = (7\text{ cm})\cos 6\pi t$ to $x = A\cos(\omega t + \delta)$:

$$A = \boxed{7.00\,\text{cm}}$$

(*d*) $x = 0$ when $\cos\omega t = 0$:

$$\omega t = \cos^{-1} 0 = \frac{\pi}{2}$$

Solve for t:

$$t = \frac{\pi}{2\omega} = \frac{\pi}{2(6\pi)} = \boxed{0.0833\,\text{s}}$$

Differentiate x to find $v(t)$:

$$v = \frac{d}{dt}[(7\,\text{cm})\cos 6\pi t] = -(42\pi\,\text{cm/s})\sin 6\pi t$$

Evaluate $v(0.0833\text{ s})$:

$$v(0.0833\,\text{s}) = -(42\pi\,\text{cm/s})\sin 6\pi(0.0833\,\text{s}) < 0$$

$$\boxed{\text{Because } v < 0\text{, the particle is moving in the negative direction at } t = 0.0833\,\text{s.}}$$

24 •

Picture the Problem The initial position of the oscillating particle is related to the amplitude and phase constant of the motion by $x_0 = A\cos\delta$ where $0 \le \delta < 2\pi$.

(*a*) For $x_0 = 0$:

$$\cos\delta = 0$$

and

$$\delta = \cos^{-1} 0 = \boxed{\frac{\pi}{2}, \frac{3\pi}{2}}$$

(*b*) For $x_0 = -A$:

$$-A = A\cos\delta$$

and

$$\delta = \cos^{-1}(-1) = \boxed{\pi}$$

(*c*) For $x_0 = A$:

$$A = A\cos\delta$$

and

$$\delta = \cos^{-1}(1) = \boxed{0}$$

(*d*) When $x = A/2$:

$$\frac{A}{2} = A\cos\delta$$

and

$$\delta = \cos^{-1}\left(\frac{1}{2}\right) = \boxed{\frac{\pi}{3}}$$

***25 •**

Picture the Problem The position of the particle as a function of time is given by $x = A\cos(\omega t + \delta)$. Its velocity as a function of time is given by $v = -A\omega\sin(\omega t + \delta)$ and its acceleration by $a = -A\omega^2\cos(\omega t + \delta)$. The initial position and velocity give us two equations from which to determine the amplitude A and phase constant δ.

(*a*) Express the position, velocity, and acceleration of the particle as a function of t:

$$x = A\cos(\omega t + \delta) \quad (1)$$

$$v = -A\omega\sin(\omega t + \delta) \quad (2)$$

$$a = -A\omega^2\cos(\omega t + \delta) \quad (3)$$

Find the angular frequency of the particle's motion:

$$\omega = \frac{2\pi}{T} = \frac{4\pi}{3}\,\text{s}^{-1} = 4.19\,\text{s}^{-1}$$

Relate the initial position and velocity to the amplitude and phase constant:

$$x_0 = A\cos\delta$$

and

$$v_0 = -\omega A\sin\delta$$

Divide these equations to eliminate A:

$$\frac{v_0}{x_0} = \frac{-\omega A\sin\delta}{A\cos\delta} = -\omega\tan\delta$$

Solve for δ and substitute numerical values to obtain:

$$\delta = \tan^{-1}\left(-\frac{v_0}{x_0\omega}\right) = \tan^{-1}\left(-\frac{0}{x_0\omega}\right) = 0$$

Substitute in equation (1) to obtain:

$$x = (25\,\text{cm})\cos\left[\left(\frac{4\pi}{3}\text{s}^{-1}\right)t\right]$$
$$= \boxed{(25\,\text{cm})\cos\left[\left(4.19\,\text{s}^{-1}\right)t\right]}$$

(*b*) Substitute in equation (2) to obtain:

$$v = -(25\,\text{cm})\left(\frac{4\pi}{3}\text{s}^{-1}\right)\sin\left[\left(\frac{4\pi}{3}\text{s}^{-1}\right)t\right]$$
$$= \boxed{-(105\,\text{cm/s})\sin\left[\left(4.19\,\text{s}^{-1}\right)t\right]}$$

(*c*) Substitute in equation (3) to obtain:

$$a = -(25\,\text{cm})\left(\frac{4\pi}{3}\text{s}^{-1}\right)^2\cos\left[\left(\frac{4\pi}{3}\text{s}^{-1}\right)t\right]$$
$$= \boxed{-\left(439\,\text{cm/s}^2\right)\cos\left[\left(4.19\,\text{s}^{-1}\right)t\right]}$$

26 •

Picture the Problem The maximum speed and maximum acceleration of the particle in are given by $v_{max} = A\omega$ and $a_{max} = A\omega^2$. The particle's position is given by $x = A\cos(\omega t + \delta)$ where $A = 7$ cm, $\omega = 6\pi\,\text{s}^{-1}$, and $\delta = 0$, and its velocity is given by $v = -A\omega\sin(\omega t + \delta)$.

(*a*) Express v_{max} in terms of A and ω:

$$v_{max} = A\omega = (7\,\text{cm})\left(6\pi\,\text{s}^{-1}\right)$$
$$= 42\pi\,\text{cm/s} = \boxed{1.32\,\text{m/s}}$$

(*b*) Express a_{max} in terms of A and ω:

$$a_{max} = A\omega^2 = (7\,\text{cm})\left(6\pi\,\text{s}^{-1}\right)^2$$
$$= 252\pi^2\,\text{cm/s}^2 = \boxed{24.9\,\text{m/s}^2}$$

(*c*) When $x = 0$:

$$\cos\omega t = 0$$

and

$$\omega t = \cos^{-1}0 = \frac{\pi}{2}, \frac{3\pi}{2}$$

Evaluate v at $\omega t = \dfrac{\pi}{2}$:

$$v = -A\omega\sin\left(\frac{\pi}{2}\right) = -A\omega$$

i.e., the particle is moving to the left.

Evaluate v at $\omega t = \frac{3\pi}{2}$:

$$v = -A\omega \sin\left(\frac{3\pi}{2}\right) = A\omega$$

i.e., the particle is moving to the right.

Solve for t:

$$t = \frac{3\pi}{2\omega} = \frac{3\pi}{2(6\pi\,\text{s}^{-1})} = \boxed{0.250\,\text{s}}$$

27 ••

Picture the Problem The position of the particle as a function of time is given by $x = A\cos(\omega t + \delta)$. Its velocity as a function of time is given by $v = -A\omega\sin(\omega t + \delta)$ and its acceleration by $a = -A\omega^2\cos(\omega t + \delta)$. The initial position and velocity give us two equations from which to determine the amplitude A and phase constant δ.

(*a*) Express the position, velocity, and acceleration of the particle as functions of t:

$$x = A\cos(\omega t + \delta) \quad (1)$$
$$v = -A\omega\sin(\omega t + \delta) \quad (2)$$
$$a = -A\omega^2\cos(\omega t + \delta) \quad (3)$$

Find the angular frequency of the particle's motion:

$$\omega = \frac{2\pi}{T} = \frac{4\pi}{3}\text{s}^{-1} = 4.19\,\text{s}^{-1}$$

Relate the initial position and velocity to the amplitude and phase constant:

$$x_0 = A\cos\delta$$

and

$$v_0 = -\omega A\sin\delta$$

Divide these equations to eliminate A:

$$\frac{v_0}{x_0} = \frac{-\omega A\sin\delta}{A\cos\delta} = -\omega\tan\delta$$

Solve for δ:

$$\delta = \tan^{-1}\left(-\frac{v_0}{x_0\omega}\right)$$

Substitute numerical values and evaluate δ:

$$\delta = \tan^{-1}\left(-\frac{50\,\text{cm/s}}{(25\,\text{cm})(4.192\,\text{s}^{-1})}\right) = -0.445\,\text{rad}$$

Use either the x_0 or v_0 equation (x_0 is used here) to find the amplitude:

$$A = \frac{x_0}{\cos\delta} = \frac{25\,\text{cm}}{\cos(-0.445\,\text{rad})} = 27.7\,\text{cm}$$

Substitute in equation (1) to obtain:

$$x = \boxed{(27.7\,\text{cm})\cos\left[(4.19\,\text{s}^{-1})t - 0.445\right]}$$

(*b*) Substitute in equation (2) to obtain:

$$v = -(27.7\,\text{cm})\left(\frac{4\pi}{3}\,\text{s}^{-1}\right) \times \sin\left[\left(\frac{4\pi}{3}\,\text{s}^{-1}\right)t - 0.445\right] = \boxed{-(116\,\text{cm/s})\sin\left[\left(4.19\,\text{s}^{-1}\right)t - 0.445\right]}$$

(*c*) Substitute in equation (3) to obtain:

$$a = -(27.7\,\text{cm})\left(\frac{4\pi}{3}\,\text{s}^{-1}\right)^2 \cos\left[\left(\frac{4\pi}{3}\,\text{s}^{-1}\right)t - 0.445\right] = \boxed{-\left(486\,\text{cm/s}^2\right)\cos\left[\left(4.19\,\text{s}^{-1}\right)t - 0.445\right]}$$

28 ••

Picture the Problem The position of the particle as a function of time is given by $x = A\cos(\omega t + \delta)$. We're given the amplitude A of the motion and can use the initial position of the particle to determine the phase constant δ. Once we've determined these quantities, we can express the distance traveled Δx during any interval of time.

Express the position of the particle as a function of t:

$$x = (12\,\text{cm})\cos(\omega t + \delta) \qquad (1)$$

Find the angular frequency of the particle's motion:

$$\omega = \frac{2\pi}{T} = \frac{2\pi}{8\,\text{s}} = \frac{\pi}{4}\,\text{s}^{-1}$$

Relate the initial position of the particle to the amplitude and phase constant:

$$x_0 = A\cos\delta$$

Solve for δ:

$$\delta = \cos^{-1}\frac{x_0}{A} = \cos^{-1}\frac{0}{A} = \frac{\pi}{2}$$

Substitute in equation (1) to obtain:

$$x = (12\,\text{cm})\cos\left[\left(\frac{\pi}{4}\,\text{s}^{-1}\right)t + \frac{\pi}{2}\right]$$

Express the distance the particle travels in terms of t_f and t_i:

$$\Delta x = \left|(12\,\text{cm})\cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)t_f + \frac{\pi}{2}\right] - (12\,\text{cm})\cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)t_i + \frac{\pi}{2}\right]\right|$$

$$= \left|(12\,\text{cm})\left\{\cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)t_f + \frac{\pi}{2}\right] - \cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)t_i + \frac{\pi}{2}\right]\right\}\right|$$

(*a*) Evaluate Δx for $t_f = 2$ s, $t_i = 1$ s:

$$\Delta x = \left|(12\,\text{cm})\left\{\cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)(2\,\text{s}) + \frac{\pi}{2}\right] - \cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)(0) + \frac{\pi}{2}\right]\right\}\right|$$

$$= \left|(12\,\text{cm})\{-1 - 0\}\right|$$

$$= \boxed{12.0\,\text{cm}}$$

(*b*) Evaluate Δx for $t_f = 4$ s, $t_i = 2$ s:

$$\Delta x = \left|(12\,\text{cm})\left\{\cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)(4\,\text{s}) + \frac{\pi}{2}\right] - \cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)(2\,\text{s}) + \frac{\pi}{2}\right]\right\}\right|$$

$$= \left|(12\,\text{cm})\{0 - 1\}\right|$$

$$= \boxed{12.0\,\text{cm}}$$

(*c*) Evaluate Δx for $t_f = 1$ s, $t_i = 0$:

$$\Delta x = \left|(12\,\text{cm})\left\{\cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)(1\,\text{s}) + \frac{\pi}{2}\right] - \cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)(0) + \frac{\pi}{2}\right]\right\}\right|$$

$$= \left|(12\,\text{cm})\{-0.7071 - 0\}\right|$$

$$= \boxed{8.49\,\text{cm}}$$

(*d*) Evaluate Δx for $t_f = 2$ s, $t_i = 1$ s:

$$\Delta x = \left|(12\,\text{cm})\left\{\cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)(2\,\text{s})+\frac{\pi}{2}\right] - \cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)(1\,\text{s})+\frac{\pi}{2}\right]\right\}\right|$$
$$= |(12\,\text{cm})\{-1+0.7071\}|$$
$$= \boxed{3.51\,\text{cm}}$$

29 ••

Picture the Problem The position of the particle as a function of time is given by $x = (10\,\text{cm})\cos(\omega t + \delta)$. We can determine the angular frequency ω from the period of the motion and the phase constant δ from the initial position and velocity. Once we've determined these quantities, we can express the distance traveled Δx during any interval of time.

Express the position of the particle as a function of *t*:

$$x = (10\,\text{cm})\cos(\omega t + \delta) \qquad (1)$$

Find the angular frequency of the particle's motion:

$$\omega = \frac{2\pi}{T} = \frac{2\pi}{8\,\text{s}} = \frac{\pi}{4}\text{s}^{-1}$$

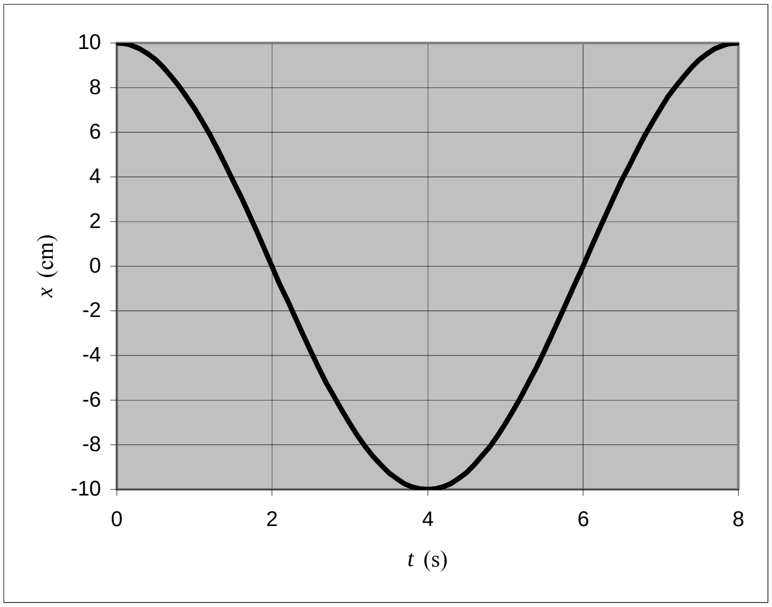
Find the phase constant of the motion:

$$\delta = \tan^{-1}\left(-\frac{v_0}{x_0\omega}\right) = \tan^{-1}\left(-\frac{0}{x_0\omega}\right) = 0$$

Substitute in equation (1) to obtain:

$$x = (10\,\text{cm})\cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)t\right]$$

(*a*) A graph of $x=(10\,\text{cm})\cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)t\right]$ follows:



(*b*) Express the distance the particle travels in terms of t_f and t_i:

$$\Delta x=\left|(10\,\text{cm})\cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)t_f\right]-(10\,\text{cm})\cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)t_i\right]\right|$$
$$=\left|(10\,\text{cm})\left\{\cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)t_f\right]-\cos\left[\left(\frac{\pi}{4}\text{s}^{-1}\right)t_i\right]\right\}\right| \quad (2)$$

Substitute numerical values in equation (2) and evaluate Δx in each of the given time intervals to obtain:

t_f	t_i	Δx
(s)	(s)	(cm)
1	0	2.93
2	1	7.07
3	2	7.07
4	3	2.93

***30 ••**

Picture the Problem We can use the expression for the maximum acceleration of an oscillator to relate the 10*g* military specification to the compliance frequency.

Express the maximum acceleration of an oscillator:

$$a_{max}=A\omega^2$$

Express the relationship between the angular frequency and the frequency of the vibrations:

$$\omega = 2\pi f$$

Substitute to obtain:

$$a_{max} = 4\pi^2 A f^2$$

Solve for f:

$$f = \frac{1}{2\pi}\sqrt{\frac{a_{max}}{A}}$$

Substitute numerical values and evaluate f:

$$f = \frac{1}{2\pi}\sqrt{\frac{98.1\,\text{m/s}^2}{1.5\times10^{-2}\,\text{m}}} = \boxed{12.9\,\text{Hz}}$$

31 ••

Picture the Problem The maximum speed and acceleration of the particle are given by $v_{max} = A\omega$ and $a_{max} = A\omega^2$. The velocity and acceleration of the particle are given by $v = -A\omega\sin\omega t$ and $a = -A\omega^2\cos\omega t$.

(*a*) Find v_{max} from A and ω:

$$v_{max} = A\omega = (2.5\,\text{m})(\pi\,\text{s}^{-1}) = \boxed{7.85\,\text{m/s}}$$

Find a_{max} from A and ω:

$$a_{max} = A\omega^2 = (2.5\,\text{m})(\pi\,\text{s}^{-1})^2 = \boxed{24.7\,\text{m/s}^2}$$

(*b*) Use the equation for the position of the particle to relate its position at $x = 1.5$ m to the time t' to reach this position:

$$1.5\,\text{m} = (2.5\,\text{m})\cos\pi t'$$

Solve for $\pi t'$:

$$\pi t' = \cos^{-1}0.6 = 0.9273\,\text{rad}$$

Evaluate v when $\pi t = \pi t'$:

$$v = -(2.5\,\text{m})(\pi\,\text{s}^{-1})\sin(0.9273\,\text{rad}) = \boxed{-6.28\,\text{m/s}}$$

where the minus sign indicates that the particle is moving in the negative direction.

Evaluate a when $\pi t = \pi t'$:

$$a = -(2.5\,\text{m})(\pi\,\text{s}^{-1})^2\cos(0.9273\,\text{rad}) = \boxed{-14.8\,\text{m/s}^2}$$

where the minus sign indicates that the particle's acceleration is in the negative direction.

***32 ••**

Picture the Problem We can use the formula for the cosine of the sum of two angles to write $x = A_0 \cos(\omega t + \delta)$ in the desired form. We can then evaluate x and dx/dt at $t = 0$ to relate A_c and A_s to the initial position and velocity of a particle undergoing simple harmonic motion.

(*a*) Apply the trigonometric identity $\cos(\omega t + \delta) = \cos\omega t\cos\delta - \sin\omega t\sin\delta$ to obtain:

$$x = A_0\cos(\omega t + \delta) = A_0[\cos\omega t\cos\delta - \sin\omega t\sin\delta]$$
$$= -A_0\sin\delta\sin\omega t + A_0\cos\delta\cos\omega t$$
$$= \boxed{A_s\sin\omega t + A_c\cos\omega t}$$

provided

$A_s = -A_0\sin\delta$ and $A_c = A_0\cos\delta$

(*b*) At $t = 0$:

$$x(0) = \boxed{A_0\cos\delta = A_c}$$

Evaluate dx/dt:

$$v = \frac{dx}{dt} = \frac{d}{dt}[A_s\sin\omega t + A_c\cos\omega t]$$
$$= A_s\omega\cos\omega t - A_c\omega\sin\omega t$$

Evaluate $v(0)$ to obtain:

$$v(0) = \omega A_s = \boxed{-\omega A_0\sin\delta}$$

Simple Harmonic Motion and Circular Motion

33 •

Picture the Problem We can find the period of the motion from the time required for the particle to travel completely around the circle. The frequency of the motion is the reciprocal of its period and the *x*-component of the particle's position is given by $x = A\cos(\omega t + \delta)$.

(*b*) Use the definition of speed to find the period of the motion:

$$T = \frac{2\pi r}{v} = \frac{2\pi(0.4\,\text{m})}{0.8\,\text{m/s}} = \boxed{3.14\,\text{s}}$$

(*a*) Because the frequency and the period are reciprocals of each other:

$$f = \frac{1}{T} = \frac{1}{3.14\,\text{s}} = \boxed{0.318\,\text{Hz}}$$

(*c*) Express the *x* component of the

$$x = A\cos(\omega t + \delta)$$

position of the particle:

Assuming that the particle is on the positive x axis at time $t = 0$:

$$A = A\cos\delta \Rightarrow \delta = \cos^{-1}1 = 0$$

Substitute for A, ω, and δ to obtain:

$$x = A\cos(2\pi ft) = \boxed{(40\,\text{cm})\cos\left[\left(2\,\text{s}^{-1}\right)t\right]}$$

***34** •

Picture the Problem We can find the period of the motion from the time required for the particle to travel completely around the circle. The angular frequency of the motion is 2π times the reciprocal of its period and the x-component of the particle's position is given by $x = A\cos(\omega t + \delta)$.

(*a*) Use the definition of speed to express and evaluate the speed of the particle:

$$v = \frac{2\pi r}{T} = \frac{2\pi(15\,\text{cm})}{3\,\text{s}} = \boxed{31.4\,\text{cm/s}}$$

(*b*) Express the angular velocity of the particle:

$$\omega = \frac{2\pi}{T} = \boxed{\frac{2\pi}{3}\,\text{rad/s}}$$

(*c*) Express the x component of the position of the particle:

$$x = A\cos(\omega t + \delta)$$

Assuming that the particle is on the positive x axis at time $t = 0$:

$$A = A\cos\delta \Rightarrow \delta = \cos^{-1}1 = 0$$

Substitute to obtain:

$$x = \boxed{(15\,\text{cm})\cos\left(\frac{2\pi}{3}\,\text{s}^{-1}\right)t}$$

Energy in Simple Harmonic Motion

35 •

Picture the Problem The total energy of the object is given by $E_{\text{tot}} = \frac{1}{2}kA^2$, where A is the amplitude of the object's motion.

Express the total energy of the system:

$$E_{\text{tot}} = \tfrac{1}{2}kA^2$$

Substitute numerical values and evaluate E_{tot}:

$$E_{\text{tot}} = \tfrac{1}{2}(4.5\,\text{kN/m})(0.1\,\text{m})^2 = \boxed{22.5\,\text{J}}$$

36 •

Picture the Problem The total energy of an oscillating object can be expressed in terms of its kinetic energy as it passes through its equilibrium position: $E_{tot} = \frac{1}{2}mv_{max}^2$. Its maximum speed, in turn, can be expressed in terms of its angular frequency and the amplitude of its motion.

Express the total energy of the object in terms of its maximum kinetic energy:

$$E = \tfrac{1}{2}mv_{max}^2$$

Express v_{max}:

$$v_{max} = A\omega = 2\pi Af$$

Substitute to obtain:

$$E = \tfrac{1}{2}m(2\pi Af)^2 = 2mA^2\pi^2 f^2$$

Substitute numerical values and evaluate E:

$$E = 2(3\,\text{kg})(0.1\,\text{m})^2\pi^2\left(2.4\,\text{s}^{-1}\right)^2 = \boxed{3.41\,\text{J}}$$

37 •

Picture the Problem The total mechanical energy of the oscillating object can be expressed in terms of its kinetic energy as it passes through its equilibrium position: $E_{tot} = \frac{1}{2}mv_{max}^2$. Its total energy is also given by $E_{tot} = \frac{1}{2}kA^2$. We can equate these expressions to obtain an expression for A.

(*a*) Express the total mechanical energy of the object in terms of its maximum kinetic energy:

$$E = \tfrac{1}{2}mv_{max}^2$$

Substitute numerical values and evaluate E:

$$E = \tfrac{1}{2}(1.5\,\text{kg})(0.7\,\text{m/s})^2 = \boxed{0.368\,\text{J}}$$

(*b*) Express the total energy of the object in terms of the amplitude of its motion:

$$E_{tot} = \tfrac{1}{2}kA^2$$

Solve for A:

$$A = \sqrt{\frac{2E_{tot}}{k}}$$

Substitute numerical values and evaluate A:

$$A = \sqrt{\frac{2(0.368\,\text{J})}{500\,\text{N/m}}} = \boxed{3.84\,\text{cm}}$$

38 •

Picture the Problem The total energy of the oscillating object can be expressed in terms of its kinetic energy as it passes through its equilibrium position: $E_{tot} = \frac{1}{2}mv_{max}^2$. Its total energy is also given by $E_{tot} = \frac{1}{2}kA^2$. We can solve the latter equation to find *A* and solve the former equation for v_{max}.

(*a*) Express the total energy of the object as a function of the amplitude of its motion:

$$E_{tot} = \frac{1}{2}kA^2$$

Solve for *A*:

$$A = \sqrt{\frac{2E_{tot}}{k}}$$

Substitute numerical values and evaluate *A*:

$$A = \sqrt{\frac{2(0.9\,\text{J})}{2000\,\text{N/m}}} = \boxed{3.00\,\text{cm}}$$

(*b*) Express the total energy of the object in terms of its maximum speed:

$$E_{tot} = \frac{1}{2}mv_{max}^2$$

Solve for v_{max}:

$$v_{max} = \sqrt{\frac{2E_{tot}}{m}}$$

Substitute numerical values and evaluate v_{max}:

$$v_{max} = \sqrt{\frac{2(0.9\,\text{J})}{3\,\text{kg}}} = \boxed{0.775\,\text{m/s}}$$

39 •

Picture the Problem The total energy of the object is given by $E_{tot} = \frac{1}{2}kA^2$. We can solve this equation for the force constant *k* and substitute the numerical data to determine its value.

Express the total energy of the oscillator as a function of the amplitude of its motion:

$$E_{tot} = \frac{1}{2}kA^2$$

Solve for *k*:

$$k = \frac{2E_{tot}}{A^2}$$

Substitute numerical values and evaluate *k*:

$$k = \frac{2(1.4\,\text{J})}{(0.045\,\text{m})^2} = \boxed{1.38\,\text{kN/m}}$$

***40 ••**

Picture the Problem The total energy of the object is given, in terms of its maximum kinetic energy by $E_{tot} = \frac{1}{2}mv_{max}^2$. We can express v_{max} in terms of A and ω and, in turn, express ω in terms of a_{max} to obtain an expression for E_{tot} in terms of a_{max}.

Express the total energy of the object in terms of its maximum kinetic energy:

$$E_{tot} = \tfrac{1}{2}mv_{max}^2$$

Relate the maximum speed of the object to its angular frequency:

$$v_{max} = A\omega$$

Substitute to obtain:

$$E_{tot} = \tfrac{1}{2}m(A\omega)^2 = \tfrac{1}{2}mA^2\omega^2$$

Relate the maximum acceleration of the object to its angular frequency:

$$a_{max} = A\omega^2$$

or

$$\omega^2 = \frac{a_{max}}{A}$$

Substitute and simplify to obtain:

$$E_{tot} = \tfrac{1}{2}mA^2\frac{a_{max}}{A} = \tfrac{1}{2}mAa_{max}$$

Substitute numerical values and evaluate E_{tot}:

$$E_{tot} = \tfrac{1}{2}(3\,\text{kg})(0.08\,\text{m})(3.50\,\text{m/s}^2) = \boxed{0.420\,\text{J}}$$

Springs

41 •

Picture the Problem The frequency of the object's motion is given by $f = \frac{1}{2\pi}\sqrt{k/m}$.

Its period is the reciprocal of its frequency. The maximum velocity and acceleration of an object executing simple harmonic motion are $v_{max} = A\omega$ and $a_{max} = A\omega^2$, respectively.

(*a*) The frequency of the motion is given by:

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{m}}$$

Substitute numerical values and evaluate f:

$$f = \frac{1}{2\pi}\sqrt{\frac{4.5\,\text{kN/m}}{2.4\,\text{kg}}} = \boxed{6.89\,\text{Hz}}$$

(*b*) The period of the motion to is the reciprocal of its frequency:

$$T=\frac{1}{f}=\frac{1}{6.89\,\text{s}^{-1}}=\boxed{0.145\,\text{s}}$$

(*c*) Because the object is released from rest after the spring to which it is attached is stretched 10 cm:

$$A=\boxed{0.100\,\text{m}}$$

(*d*) Express the object's maximum speed:

$$v_{\text{max}}=A\omega=2\pi fA$$

Substitute numerical values and evaluate v_{max}:

$$v_{\text{max}}=2\pi\left(6.89\,\text{s}^{-1}\right)(0.1\,\text{m})=\boxed{4.33\,\text{m/s}}$$

(*e*) Express the object's maximum acceleration:

$$a_{\text{max}}=A\omega^2=\omega v_{\text{max}}=2\pi f v_{\text{max}}$$

Substitute numerical values and evaluate a_{max}:

$$a_{\text{max}}=2\pi\left(6.89\,\text{s}^{-1}\right)(4.33\,\text{m/s})=\boxed{187\,\text{m/s}^2}$$

(*f*) The object first reaches its equilibrium when:

$$t=\tfrac{1}{4}T=\tfrac{1}{4}(0.145\,\text{s})=\boxed{36.3\,\text{ms}}$$

Because the resultant force acting on the object as it passes through its equilibrium point is zero, the acceleration of the object is:

$$a=\boxed{0}$$

42 •

Picture the Problem The frequency of the object's motion is given by $f=\frac{1}{2\pi}\sqrt{k/m}$. Its period is the reciprocal of its frequency. The maximum velocity and acceleration of an object executing simple harmonic motion are $v_{\text{max}}=A\omega$ and $a_{\text{max}}=A\omega^2$, respectively.

(*a*) The frequency of the motion is given by:

$$f=\frac{1}{2\pi}\sqrt{\frac{k}{m}}$$

Substitute numerical values and evaluate *f*:

$$f=\frac{1}{2\pi}\sqrt{\frac{700\,\text{N/m}}{5\,\text{kg}}}=\boxed{1.88\,\text{Hz}}$$

(*b*) The period of the motion is the reciprocal of its frequency:

$$T=\frac{1}{f}=\frac{1}{1.88\,\text{s}^{-1}}=\boxed{0.531\,\text{s}}$$

(*c*) Because the object is released from rest after the spring to which it is attached is stretched 8 cm:

$$A=\boxed{0.0800\,\text{m}}$$

(*d*) Express the object's maximum speed:

$$v_{max}=A\omega=2\pi fA$$

Substitute numerical values and evaluate v_{max}:

$$v_{max}=2\pi\left(1.88\,\text{s}^{-1}\right)\left(0.08\,\text{m}\right)=\boxed{0.945\,\text{m/s}}$$

(*e*) Express the object's maximum acceleration:

$$a_{max}=A\omega^2=\omega v_{max}=2\pi f v_{max}$$

Substitute numerical values and evaluate a_{max}:

$$a_{max}=2\pi\left(1.88\,\text{s}^{-1}\right)\left(0.945\,\text{m/s}\right)=\boxed{11.2\,\text{m/s}^2}$$

(*f*) The object first reaches its equilibrium when:

$$t=\tfrac{1}{4}T=\tfrac{1}{4}\left(0.531\,\text{s}\right)=\boxed{0.133\,\text{s}}$$

Because the resultant force acting on the object as it passes through its equilibrium point is zero, the acceleration of the object is:

$$a=\boxed{0}$$

43 •

Picture the Problem The angular frequency, in terms of the force constant of the spring and the mass of the oscillating object, is given by $\omega^2=k/m$. The period of the motion is the reciprocal of its frequency. The maximum velocity and acceleration of an object executing simple harmonic motion are $v_{max}=A\omega$ and $a_{max}=A\omega^2$, respectively.

(*a*) Relate the angular frequency of the motion to the force constant of the spring:

$$\omega^2=\frac{k}{m}$$

or

$$k=m\omega^2=4\pi^2f^2m$$

Substitute numerical values to obtain:

$$k=4\pi^2\left(2.4\,\text{s}^{-1}\right)^2\left(3\,\text{kg}\right)=\boxed{682\,\text{N/m}}$$

(*b*) Relate the period of the motion to its frequency:

$$T = \frac{1}{f} = \frac{1}{2.4\,\text{s}^{-1}} = \boxed{0.417\,\text{s}}$$

(*c*) Express the maximum speed of the object:

$$v_{\max} = A\omega = 2\pi f A$$

Substitute numerical values and evaluate $v_{\max}$:

$$v_{\max} = 2\pi\left(2.4\,\text{s}^{-1}\right)(0.1\,\text{m}) = \boxed{1.51\,\text{m/s}}$$

(*d*) Express the maximum acceleration of the object:

$$a_{\max} = A\omega^2 = 4\pi^2 f^2 A$$

Substitute numerical values and evaluate $a_{\max}$:

$$a_{\max} = 4\pi^2\left(2.4\,\text{s}^{-1}\right)^2(0.1\,\text{m}) = \boxed{22.7\,\text{m/s}^2}$$

***44 •**

Picture the Problem We can find the frequency of vibration of the car-and-passenger system using $f = \frac{1}{2\pi}\sqrt{\frac{k}{M}}$, where *M* is the total mass of the system. The spring constant can be determined from the compressing force and the amount of compression.

Express the frequency of the car-and-passenger system:

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{M}}$$

Express the spring constant:

$$k = \frac{F}{\Delta x} = \frac{mg}{\Delta x}$$

where *m* is the person's mass.

Substitute to obtain:

$$f = \frac{1}{2\pi}\sqrt{\frac{mg}{M\Delta x}}$$

Substitute numerical values and evaluate *f*:

$$f = \frac{1}{2\pi}\sqrt{\frac{(85\,\text{kg})\left(9.81\,\text{m/s}^2\right)}{(2485\,\text{kg})\left(2.35\times10^{-2}\,\text{m}\right)}} = \boxed{0.601\,\text{Hz}}$$

45 •

Picture the Problem We can relate the force constant *k* to the maximum acceleration by eliminating ω^2 between $\omega^2 = k/m$ and $a_{\max} = A\omega^2$. We can also express the frequency f

of the motion by substituting ma_{max}/A for k in $f=\frac{1}{2\pi}\sqrt{\frac{k}{m}}$.

(*a*) Relate the angular frequency of the motion to the force constant and the mass of the oscillator:

$$\omega^2=\frac{k}{m} \text{ or } k=\omega^2 m$$

Relate the object's maximum acceleration to its angular frequency and amplitude and solve for the square of the angular frequency:

$$a_{max}=A\omega^2$$

or

$$\omega^2=\frac{a_{max}}{A} \qquad (1)$$

Substitute to obtain:

$$k=\frac{ma_{max}}{A}$$

Substitute numerical values and evaluate k:

$$k=\frac{(4.5\,\text{kg})(26\,\text{m/s}^2)}{3.8\times10^{-2}\,\text{m}}=\boxed{3.08\,\text{kN/m}}$$

(*b*) Replace ω in equation (1) by $2\pi f$ and solve for f to obtain:

$$f=\frac{1}{2\pi}\sqrt{\frac{a_{max}}{A}}$$

Substitute numerical values and evaluate f:

$$f=\frac{1}{2\pi}\sqrt{\frac{26\,\text{m/s}^2}{3.8\times10^{-2}\,\text{m}}}=\boxed{4.16\,\text{Hz}}$$

(*c*) The period of the motion is the reciprocal of its frequency:

$$T=\frac{1}{f}=\frac{1}{4.16\,\text{s}^{-1}}=\boxed{0.240\,\text{s}}$$

46 •

Picture the Problem We can find the frequency of the motion from its maximum speed and the relationship between frequency and angular frequency. The mass of the object can be found by eliminating ω between $\omega^2=k/m$ and $v_{max}=A\omega$.

(*b*) Express the object's maximum speed as a function of the frequency of its motion:

$$v_{max}=A\omega=2\pi fA \qquad (1)$$

Solve for f:

$$f=\frac{v_{max}}{2\pi A}$$

Substitute numerical values and evaluate f:

$$f=\frac{2.2\,\text{m/s}}{2\pi(5.8\times10^{-2}\,\text{m})}=\boxed{6.04\,\text{Hz}}$$

(*a*) Relate the square of the angular frequency of the motion to the force constant and the mass of the object:

$$\omega^2 = \frac{k}{m} \Rightarrow m = \frac{k}{\omega^2} \qquad (2)$$

Eliminate ω between equations (1) and (2) to obtain:

$$m = \frac{kA^2}{v_{max}^2}$$

Substitute numerical values and evaluate *m*:

$$m = \frac{(1.8\times10^3\ \text{N/m})(5.8\times10^{-2}\ \text{m})^2}{(2.2\ \text{m/s})^2} = \boxed{1.25\ \text{kg}}$$

(*c*) The period of the motion is the reciprocal of its frequency:

$$T = \frac{1}{f} = \frac{1}{6.04\ \text{s}^{-1}} = \boxed{0.166\ \text{s}}$$

47 ••

Picture the Problem The maximum speed of the block is given by $v_{max} = A\omega$ and the angular frequency of the motion is $\omega = \sqrt{k/m} = 5.48\ \text{rad/s}$. We'll assume that the position of the block is given by $x = A\cos\omega t$ and solve for ωt for *x* = 4 cm and *x* = 0. We can use these values for ωt to find the time for the block to travel from *x* = 4 cm to its equilibrium position.

(*a*) Express the maximum speed of the block as a function of the system's angular frequency:

$$v_{max} = A\omega$$

Substitute numerical values and evaluate v_{max}:

$$v_{max} = (0.08\ \text{m})(5.48\ \text{rad/s}) = \boxed{0.438\ \text{m/s}}$$

(*b*) Assuming that $x = A\cos\omega t$, evaluate ωt for *x* = 4 cm = *A*/2:

$$\frac{A}{2} = A\cos\omega t \Rightarrow \omega t = \cos^{-1}\frac{1}{2} = \frac{\pi}{3}$$

Evaluate *v* for $\omega t = \pi/3$:

$$v = v_{max}\sin\omega t = (0.438\ \text{m/s})\sin\frac{\pi}{3} = (0.438\ \text{m/s})\frac{\sqrt{3}}{2} = \boxed{0.379\ \text{m/s}}$$

Express *a* as a function of v_{max} and ω:

$$a = A\omega^2\cos\omega t = v_{max}\,\omega\cos\omega t$$

Substitute numerical values and evaluate a:

$$a = (0.438\,\text{m/s})(5.48\,\text{rad/s})\cos\frac{\pi}{3}$$
$$= \boxed{1.20\,\text{m/s}^2}$$

(*c*) Evaluate ωt for $x = 0$:

$$0 = A\cos\omega t \Rightarrow \omega t = \cos^{-1}0 = \frac{\pi}{2}$$

Let Δt = time to go from $\omega t = \pi/3$ to $\omega t = \pi/2$. Then:

$$\omega\Delta t = \frac{\pi}{2} - \frac{\pi}{3} = \frac{\pi}{6}$$

Solve for and evaluate Δt:

$$\Delta t = \frac{\pi}{6\omega} = \frac{\pi}{6(5.48\,\text{rad/s})} = \boxed{95.5\,\text{ms}}$$

***48 ••**

Picture the Problem Choose a coordinate system in which upward is the positive y direction. We can find the mass of the object using $m = k/\omega^2$. We can apply a condition for translational equilibrium to the object when it is at its equilibrium position to determine the amount the spring has stretched from its natural length. Finally, we can use the initial conditions to determine A and δ and express $x(t)$ and then differentiate this expression to obtain $v(t)$ and $a(t)$.

(*a*) Express the angular frequency of the system in terms of the mass of the object fastened to the vertical spring and solve for the mass of the object:

$$\omega^2 = \frac{k}{m} \Rightarrow m = \frac{k}{\omega^2}$$

Express ω^2 in terms of f:

$$\omega^2 = 4\pi^2 f^2$$

Substitute to obtain:

$$m = \frac{k}{4\pi^2 f^2}$$

Substitute numerical values and evaluate m:

$$m = \frac{1800\,\text{N/m}}{4\pi^2(5.5\,\text{s}^{-1})^2} = \boxed{1.51\,\text{kg}}$$

(*b*) Letting Δx represent the amount the spring is stretched from its natural length when the object is in equilibrium, apply $\sum F_y = 0$ to the object when it is in equilibrium:

$$k\Delta x - mg = 0$$

Solve for Δx:

$$\Delta x = \frac{mg}{k}$$

Substitute numerical values and evaluate Δx:

$$\Delta x = \frac{(1.51\,\text{kg})(9.81\,\text{m/s}^2)}{1800\text{ N/m}} = \boxed{8.23\,\text{mm}}$$

(*c*) Express the position of the object as a function of time:

$$x = A\cos(\omega t + \delta)$$

Use the initial conditions ($x_0 = -2.5$ cm and $v_0 = 0$) to find δ:

$$\delta = \tan^{-1}\left(-\frac{v_0}{\omega x_0}\right) = \tan^{-1} 0 = \pi$$

Evaluate ω:

$$\omega = \sqrt{\frac{k}{m}} = \sqrt{\frac{1800\,\text{N/m}}{1.51\,\text{kg}}} = 34.5\,\text{rad/s}$$

Substitute to obtain:

$$x = (2.5\,\text{cm})\cos[(34.5\,\text{rad/s})t + \pi]$$
$$= \boxed{-(2.5\,\text{cm})\cos[(34.5\,\text{rad/s})t]}$$

Differentiate $x(t)$ to obtain v:

$$v = \boxed{(86.4\,\text{cm/s})\sin[(34.5\,\text{rad/s})t]}$$

Differentiate $v(t)$ to obtain a:

$$a = \boxed{(29.8\,\text{m/s}^2)\cos[(34.5\,\text{rad/s})t]}$$

49 ••

Picture the Problem Let the system include the object and the spring. Then, the net external force acting on the system is zero. Choose $E_\text{i} = 0$ and apply the conservation of mechanical energy to the system.

Express the period of the motion in terms of its angular frequency:

$$T = \frac{2\pi}{\omega} \qquad (1)$$

Apply conservation of energy to the system:

$$E_\text{i} = E_\text{f} \text{ or } 0 = U_\text{g} + U_\text{spring}$$

Substitute for U_g and U_spring:

$$0 = -mg\Delta x + \tfrac{1}{2}k(\Delta x)^2$$

Solve for $\omega^2 = k/m$:

$$\omega^2 = \frac{k}{m} = \frac{2g}{\Delta x}$$

Substitute numerical values and evaluate ω^2:

$$\omega^2 = \frac{2(9.81\,\text{m/s}^2)}{3.42\times10^{-2}\text{ m}} = 574\,\text{rad/s}^2$$

Substitute in equation (1) to obtain:

$$T=\frac{2\pi}{\sqrt{574\,\text{rad/s}^2}}=\boxed{0.262\,\text{s}}$$

50 ••

Picture the Problem Let the system include the object and the spring. Then the net external force acting on the system is zero. Because the net force acting on the object when it is at its equilibrium position is zero, we can apply a condition for translational equilibrium to determine the distance from the starting point to the equilibrium position. Letting $E_i = 0$, we can apply conservation of energy to the system to determine how far down the object moves before coming momentarily to rest. We can find the period of the motion and the maximum speed of the object from $T=2\pi\sqrt{m/k}$ and $v_{max}=A\sqrt{k/m}$.

(*a*) Apply $\sum F_y=0$ to the object when it is at the equilibrium position:

$$ky_0-mg=0$$

Solve for y_0:

$$y_0=\frac{mg}{k}$$

Substitute numerical values and evaluate y_0:

$$y_0=\frac{(1\,\text{kg})(9.81\,\text{m/s}^2)}{250\,\text{N/m}}=\boxed{3.92\,\text{cm}}$$

(*b*) Apply conservation of energy to the system:

$$E_i=E_f$$

or

$$0=U_g+U_{spring}$$

Substitute for U_g and U_{spring}:

$$0=-mgy_f+\tfrac{1}{2}ky_f^2$$

Solve for y_f:

$$y_f=\frac{2mg}{k}$$

Substitute numerical values and evaluate y_f:

$$y_f=\frac{2(1\,\text{kg})(9.81\,\text{m/s}^2)}{250\,\text{N/m}}=\boxed{7.85\,\text{cm}}$$

(*c*) Express the period T of the motion in terms of the mass of the object and the spring constant:

$$T=2\pi\sqrt{\frac{m}{k}}$$

Substitute numerical values and evaluate T:

$$T = 2\pi\sqrt{\frac{1\,\text{kg}}{250\,\text{N/m}}} = \boxed{0.397\,\text{s}}$$

(*d*) The object will be moving with its maximum speed when it reaches its equilibrium position:

$$v_{\max} = A\omega = A\sqrt{\frac{k}{m}}$$

Substitute numerical values and evaluate $v_{\max}$:

$$v_{\max} = (3.92\,\text{cm})\sqrt{\frac{250\,\text{N/m}}{1\,\text{kg}}} = \boxed{62.0\,\text{cm/s}}$$

(*e*) The time required for the object to reach equilibrium is one-fourth of its period:

$$t = \tfrac{1}{4}T = \tfrac{1}{4}(0.397\,\text{s}) = \boxed{99.3\,\text{ms}}$$

51 ••

Picture the Problem The stunt woman's kinetic energy, after 2 s of flight, is $K_{2\text{s}} = \frac{1}{2}mv_{2\text{s}}^2$. We can evaluate this quantity as soon as we know how fast she is moving after two seconds. Because her motion is oscillatory, her velocity as a function of time is $v(t) = -A\omega\sin(\omega t + \delta)$. We can find the amplitude of her motion from her distance of fall and the angular frequency of her motion by applying conservation of energy to her fall to the ground.

Express the kinetic energy of the stunt woman when she has fallen for 2 s:

$$K_{2\text{s}} = \tfrac{1}{2}mv_{2\text{s}}^2 \qquad (1)$$

Express her velocity as a function of time:

$$v(t) = -A\omega\sin(\omega t + \delta)$$

where $\delta = 0$ (she starts from rest with positive displacement) and

$$A = \tfrac{1}{2}(192\,\text{m}) = 96\,\text{m}$$

$$\therefore v(t) = -(96\,\text{m})\omega\sin(\omega t) \qquad (2)$$

Letting $E_i = 0$, use conservation of energy to find the force constant of the elastic band:

$$0 = U_g + U_{\text{elastic}}$$

or

$$0 = -mgh + \tfrac{1}{2}kh^2 = 0$$

Solve for k:

$$k = \frac{2mg}{h}$$

Substitute numerical values and evaluate k:

$$k = \frac{2(60\,\text{kg})(9.81\,\text{m/s}^2)}{192\,\text{m}} = 6.13\,\text{N/m}$$

Express the angular frequency of her motion:

$$\omega = \sqrt{\frac{k}{m}}$$

Substitute numerical values and evaluate ω:

$$\omega = \sqrt{\frac{6.13\,\text{N/m}}{60\,\text{kg}}} = 0.320\,\text{rad/s}$$

Substitute in equation (2) to obtain:

$$\begin{aligned} v(t) &= -(96\,\text{m})(0.320\,\text{rad/s}) \\ &\quad \times \sin[(0.320\,\text{rad/s})t] \\ &= (30.7\,\text{m/s})\sin[(0.320\,\text{rad/s})t] \end{aligned}$$

Evaluate $v(2\text{ s})$:

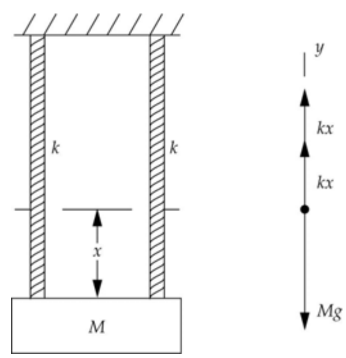
$$\begin{aligned} v(2\,\text{s}) &= (30.7\,\text{m/s})\sin[(0.320\,\text{rad/s})(2\,\text{s})] \\ &= 18.3\,\text{m/s} \end{aligned}$$

Substitute in equation (1) and evaluate $K(2\text{ s})$:

$$K(2\,\text{s}) = \tfrac{1}{2}(60\,\text{kg})(18.3\,\text{m/s})^2 = \boxed{10.1\,\text{kJ}}$$

***52 ••**

Picture the Problem The diagram shows the stretched bungie cords supporting the suitcase under equilibrium conditions. We can use $f = \frac{1}{2\pi}\sqrt{\frac{k_{\text{eff}}}{M}}$ to express the frequency of the suitcase in terms of the effective "spring" constant k_{eff} and apply a condition for translational equilibrium to the suitcase to find k_{eff}.



Express the frequency of the suitcase oscillator:

$$f = \frac{1}{2\pi}\sqrt{\frac{k_{\text{eff}}}{M}}$$

Apply $\sum F_y = 0$ to the suitcase to obtain:

$$kx + kx - Mg = 0$$

or

$$2kx - Mg = 0$$

or

$$k_{\text{eff}}x - Mg = 0$$

where $k_{\text{eff}} = 2k$

Solve for k_{eff} to obtain:

$$k_{\text{eff}} = \frac{Mg}{x}$$

Substitute to obtain:

$$f = \frac{1}{2\pi}\sqrt{\frac{g}{x}}$$

Substitute numerical values and evaluate f:

$$f = \frac{1}{2\pi}\sqrt{\frac{9.81\,\text{m/s}^2}{0.05\,\text{m}}} = \boxed{2.23\,\text{Hz}}$$

53 ••

Picture the Problem The frequency of the motion of the stone and block depends on the force constant of the spring and the mass of the stone plus block. The force constant can be determined from the equilibrium of the system when the spring is stretched additionally by the addition of the stone to the mass. When the block is at the point of maximum upward displacement, it is momentarily at rest and the net force acting on it is its weight.

(*a*) Express the frequency of the motion in terms of k and m:

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{m_{\text{tot}}}}$$

where m_{tot} is the total mass suspended from the spring.

Apply $\sum F_y = 0$ to the stone when it is at its equilibrium position:

$$k\Delta y - mg = 0$$

Solve for k:

$$k = \frac{mg}{\Delta y}$$

Substitute numerical values and evaluate k:

$$k = \frac{(0.03\,\text{kg})(9.81\,\text{m/s}^2)}{0.05\,\text{m}} = 5.89\,\text{N/m}$$

Substitute and evaluate f:

$$f = \frac{1}{2\pi}\sqrt{\frac{5.89\,\text{N/m}}{0.15\,\text{kg}}} = \boxed{0.997\,\text{Hz}}$$

(*b*) The time to travel from its lowest point to its highest point is one-half its period:

$$t = \tfrac{1}{2}T = \frac{1}{2f} = \frac{1}{2(0.997\,\text{s}^{-1})} = \boxed{0.502\,\text{s}}$$

(*c*) When the stone is at a point of maximum upward displacement:

$$F_{\text{net}} = mg = (0.03\,\text{kg})(9.81\,\text{m/s}^2) = \boxed{0.294\,\text{N}}$$

54 ••

Picture the Problem We can use the maximum acceleration of the oscillator $a_{\max} = A\omega^2$ to express $a_{\max}$ in terms of A, k, and m. k can be determined from the equilibrium of the system when the spring is stretched additionally by the addition of the stone to the mass. If the stone is to remain in contact with the block, the block's maximum downward acceleration must not exceed g.

Express the maximum acceleration in terms of the angular frequency and amplitude of the motion:

$$a_{\max} = A\omega^2$$

Relate ω^2 to the force constant and the mass of the stone:

$$\omega^2 = \frac{k}{m}$$

Substitute to obtain:

$$a_{\max} = A\frac{k}{m}$$

Apply $\sum F_y = 0$ to the stone when it is at its equilibrium position:

$$k\Delta y - mg = 0$$

Solve for k:

$$k = \frac{mg}{\Delta y}$$

Substitute numerical values and evaluate k:

$$k = \frac{(0.03\,\text{kg})(9.81\,\text{m/s}^2)}{0.05\,\text{m}} = 5.89\,\text{N/m}$$

Substitute numerical values to express $a_{\max}$ in terms of A:

$$a_{\max} = A\frac{5.89\,\text{N/m}}{0.15\,\text{kg}} = (39.3\,\text{s}^{-2})A$$

Set $a_{\max} = g$ and solve for $A_{\max}$:

$$A_{\max} = \frac{g}{39.3\,\text{s}^{-2}}$$

Substitute for g and evaluate $A_{\max}$:

$$A_{\max} = \frac{9.81\,\text{m/s}^2}{39.3\,\text{s}^{-2}} = \boxed{25.0\,\text{cm}}$$

55 ••

Picture the Problem The maximum height above the floor to which the object rises is the sum of its initial distance from the floor and the amplitude of its motion. We can find the amplitude of its motion by relating it to the object's maximum speed. Because the object initially travels downward, it will be three-fourths of the way through its cycle when it first reaches its maximum height. We can find the minimum initial speed the object would need to be given in order for the spring to become uncompressed by applying conservation of energy.

(*a*) Relate *h,* the maximum height above the floor to which the object rises, to the amplitude of its motion:

$$h = A + 5.0\text{ cm} \qquad (1)$$

Relate the maximum speed of the object to the angular frequency and amplitude of its motion and solve for the amplitude:

$$v_{max} = A\omega$$

or

$$A = v_{max}\sqrt{\frac{m}{k}} \qquad (2)$$

Using its definition, express and evaluate the force constant of the spring:

$$k = \frac{mg}{\Delta y} = \frac{(2\text{ kg})(9.81\text{ m/s}^2)}{0.03\text{ m}} = 654\text{ N/m}$$

Substitute numerical values in equation (2) and evaluate *A*:

$$A = 0.3\text{ m/s}\sqrt{\frac{2\text{ kg}}{654\text{ N/m}}} = 1.66\text{ cm}$$

Substitute in equation (1) to obtain:

$$h = 1.66\text{ cm} + 5.00\text{ cm} = \boxed{6.66\text{ cm}}$$

(*b*) Express the time required for the object to reach its maximum height the first time:

$$t = \tfrac{3}{4}T$$

Express the period of the motion:

$$T = 2\pi\sqrt{\frac{m}{k}}$$

Substitute numerical values and evaluate *T*:

$$T = 2\pi\sqrt{\frac{2\text{ kg}}{654\text{ N/m}}} = 0.347\text{ s}$$

Substitute to obtain:

$$t = \tfrac{3}{4}(0.347\text{ s}) = \boxed{0.261\text{ s}}$$

(c) Because $h < 8.0$ cm: $\boxed{\text{the spring is never uncompressed.}}$

Using conservation of energy and letting U_g be zero 5 cm above the floor, relate the height to which the object rises, Δy, to its initial kinetic energy:

$$\Delta K + \Delta U_g + \Delta U_s = 0$$

or, because $K_f = U_i = 0$,

$$\tfrac{1}{2}mv_i^2 - mg\Delta y + \tfrac{1}{2}k(\Delta y)^2 - \tfrac{1}{2}k(L - y_i)^2 = 0$$

Because $\Delta y = L - y_i$:

$$\tfrac{1}{2}mv_i^2 - mg\Delta y + \tfrac{1}{2}k(\Delta y)^2 - \tfrac{1}{2}k(\Delta y)^2 = 0$$

and

$$\tfrac{1}{2}mv_i^2 - mg\Delta y = 0$$

Solve for and evaluate v_i for $\Delta y = 3$ cm:

$$v_i = \sqrt{2g\Delta y} = \sqrt{2(9.81\,\text{m/s}^2)(3\,\text{cm})} = 0.767\,\text{m/s}$$

i.e., the minimum initial velocity that must be given to the object for the spring to be uncompressed at some time is $\boxed{0.767\,\text{m/s}}$

***56 ••**

Picture the Problem We can relate the elongation of the cable to the load on it using the definition of Young's modulus and use the expression for the frequency of a spring and mass oscillator to find the oscillation frequency of the engine block at the end of the wire.

(a) Using the definition of Young's modulus, relate the elongation of the cable to the applied stress:

$$Y = \frac{\text{stress}}{\text{strain}} = \frac{F/A}{\Delta\ell/\ell}$$

Solve for $\Delta\ell$:

$$\Delta\ell = \frac{F\ell}{AY} = \frac{Mg\ell}{AY}$$

Substitute numerical values and evaluate $\Delta\ell$:

$$\Delta\ell = \frac{(950\,\text{kg})(9.81\,\text{m/s}^2)(2.5\,\text{m})}{(1.5\,\text{cm}^2)(150\,\text{GN/m}^2)} = \boxed{1.04\,\text{mm}}$$

(b) Express the oscillation frequency of the wire-engine block system:

$$f = \frac{1}{2\pi}\sqrt{\frac{k_{\text{eff}}}{M}}$$

Express the effective "spring" constant of the cable:

$$k_{eff} = \frac{F}{\Delta\ell} = \frac{Mg}{\Delta\ell}$$

Substitute to obtain:

$$f = \frac{1}{2\pi}\sqrt{\frac{g}{\Delta\ell}}$$

Substitute numerical values and evaluate *f*:

$$f = \frac{1}{2\pi}\sqrt{\frac{9.81\,\text{m/s}^2}{1.04\,\text{mm}}} = \boxed{15.5\,\text{Hz}}$$

Energy of an Object on a Vertical Spring

57 ••

Picture the Problem Let the origin of our coordinate system be at y_0, where y_0 is the equilibrium position of the object and let $U_g = 0$ at this location. Because $F_{net} = 0$ at equilibrium, the extension of the spring is then $y_0 = mg/k$, and the potential energy stored in the spring is $U_s = \frac{1}{2}ky_0^2$. A further extension of the spring by an amount y increases U_s to $\frac{1}{2}k(y + y_0)^2 = \frac{1}{2}ky^2 + kyy_0 + \frac{1}{2}ky_0^2 = \frac{1}{2}ky^2 + mgy + \frac{1}{2}ky_0^2$. Consequently, if we set $U = U_g + U_s = 0$, a further extension of the spring by y increases U_s by $\frac{1}{2}ky^2 + mgy$ while decreasing U_g by mgy. Therefore, if $U = 0$ at the equilibrium position, the change in U is given by $\frac{1}{2}k(y')^2$, where $y' = y - y_0$.

(*a*) Express the total energy of the system:

$$E = \tfrac{1}{2}kA^2$$

Substitute numerical values and evaluate *E*:

$$E = \tfrac{1}{2}(600\,\text{N/m})(0.03\,\text{m})^2 = \boxed{0.270\,\text{J}}$$

(*b*) Express and evaluate U_g when the object is at its maximum downward displacement:

$$\begin{aligned} U_g &= -mgA \\ &= -(2.5\,\text{kg})(9.81\,\text{m/s}^2)(0.03\,\text{m}) \\ &= \boxed{-0.736\,\text{J}} \end{aligned}$$

(*c*) When the object is at its maximum downward displacement:

$$\begin{aligned} U_s &= \tfrac{1}{2}kA^2 + mgA \\ &= \tfrac{1}{2}(600\,\text{N/m})(0.03\,\text{m})^2 \\ &\quad + (2.5\,\text{kg})(9.81\,\text{m/s}^2)(0.03\,\text{m}) \\ &= \boxed{1.01\,\text{J}} \end{aligned}$$

(*d*) The object has its maximum kinetic energy when it is passing through its equilibrium position:

$$K_{max} = \tfrac{1}{2}kA^2 = \tfrac{1}{2}(600\,\text{N/m})(0.03\,\text{m})^2 = \boxed{0.270\,\text{J}}$$

58 ••

Picture the Problem Let the origin of our coordinate system be at y_0, where y_0 is the equilibrium position of the object and let $U_g = 0$ at this location. Because $F_{net} = 0$ at equilibrium, the extension of the spring is then $y_0 = mg/k$, and the potential energy stored in the spring is $U_s = \tfrac{1}{2}ky_0^2$. A further extension of the spring by an amount y increases U_s to $\tfrac{1}{2}k(y+y_0)^2 = \tfrac{1}{2}ky^2 + kyy_0 + \tfrac{1}{2}ky_0^2 = \tfrac{1}{2}ky^2 + mgy + \tfrac{1}{2}ky_0^2$. Consequently, if we set $U = U_g + U_s = 0$, a further extension of the spring by y increases U_s by $\tfrac{1}{2}ky^2 + mgy$ while decreasing U_g by mgy. Therefore, if $U = 0$ at the equilibrium position, the change in U is given by $\tfrac{1}{2}k(y')^2$, where $y' = y - y_0$.

(*a*) Express the total energy of the system:

$$E = \tfrac{1}{2}kA^2$$

Letting Δy represent the amount the spring is stretched from its natural length by the 1.5-kg object, apply $\sum F_y = ma_y$ to the object when it is in its equilibrium position:

$$k\Delta y - mg = 0$$

Solve for k:

$$k = \frac{mg}{\Delta y}$$

Substitute for k to obtain:

$$E = \frac{mgA^2}{2\Delta y}$$

Substitute numerical values and evaluate E:

$$E = \frac{(1.5\,\text{kg})(9.81\,\text{m/s}^2)(0.022\,\text{m})^2}{2(0.028\,\text{m})} = \boxed{0.127\,\text{J}}$$

(*b*) Express U_g when the object is at its maximum downward displacement:

$$U_g = -mgA$$

Substitute numerical values and evaluate U_g:

$$U_g = -(1.5\,\text{kg})(9.81\,\text{m/s}^2)(0.022\,\text{m}) = \boxed{-0.324\,\text{J}}$$

(*c*) When the object is at its maximum downward displacement:

$$U_s = \tfrac{1}{2}kA^2 + mgA$$

Substitute numerical values and evaluate U_s:

$$U_s = \tfrac{1}{2}(526\,\text{N/m})(0.022\,\text{m})^2 + (1.5\,\text{kg})(9.81\,\text{m/s}^2)(0.022\,\text{m}) = \boxed{0.451\,\text{J}}$$

(*d*) The object has its maximum kinetic energy when it is passing through its equilibrium position:

$$K_{max} = \tfrac{1}{2}kA^2 = \tfrac{1}{2}(526\,\text{N/m})(0.022\,\text{m})^2 = \boxed{0.127\,\text{J}}$$

***59 ••**

Picture the Problem We can find the amplitude of the motion by relating it to the maximum speed of the object. Let the origin of our coordinate system be at y_0, where y_0 is the equilibrium position of the object and let $U_g = 0$ at this location. Because $F_{net} = 0$ at equilibrium, the extension of the spring is then $y_0 = mg/k$, and the potential energy stored in the spring is $U_s = \tfrac{1}{2}ky_0^2$. A further extension of the spring by an amount y increases U_s to $\tfrac{1}{2}k(y+y_0)^2 = \tfrac{1}{2}ky^2 + kyy_0 + \tfrac{1}{2}ky_0^2 = \tfrac{1}{2}ky^2 + mgy + \tfrac{1}{2}ky_0^2$. Consequently, if we set $U = U_g + U_s = 0$, a further extension of the spring by y increases U_s by $\tfrac{1}{2}ky^2 + mgy$ while decreasing U_g by mgy. Therefore, if $U = 0$ at the equilibrium position, the change in U is given by $\tfrac{1}{2}k(y')^2$, where $y' = y - y_0$.

(*a*) Relate the maximum speed of the object to the amplitude of its motion:

$$v_{max} = A\omega$$

Solve for A:

$$A = \frac{v_{max}}{\omega} = v_{max}\sqrt{\frac{m}{k}}$$

Substitute numerical values and evaluate A:

$$A = (0.3\,\text{m/s})\sqrt{\frac{1.2\,\text{kg}}{300\,\text{N/m}}} = \boxed{1.90\,\text{cm}}$$

(*b*) Express the energy of the object at maximum displacement:

$$E = \tfrac{1}{2}kA^2$$

Substitute numerical values and evaluate E:

$$E = \tfrac{1}{2}(300\,\text{N/m})(0.019\,\text{m})^2 = \boxed{0.0542\,\text{J}}$$

(*c*) At maximum displacement from equilibrium:

$$U_g = -mgA$$

Substitute numerical values and evaluate U_g:

$$U_g = -(1.2\,\text{kg})(9.81\,\text{m/s}^2)(0.019\,\text{m}) = \boxed{-0.224\,\text{J}}$$

(*d*) Express the potential energy in the spring when the object is at its maximum downward displacement:

$$U_s = \tfrac{1}{2}kA^2 + mgA$$

Substitute numerical values and evaluate U_s:

$$U_s = \tfrac{1}{2}(300\,\text{N/m})(0.019\,\text{m})^2 + (1.2\,\text{kg})(9.81\,\text{m/s}^2)(0.019\,\text{m}) = \boxed{0.278\,\text{J}}$$

Simple Pendulums

60 •

Picture the Problem We can determine the required length of the pendulum from the expression for the period of a simple pendulum.

Express the period of a simple pendulum:

$$T = 2\pi\sqrt{\frac{L}{g}}$$

Solve for *L*:

$$L = \frac{T^2 g}{4\pi^2}$$

Substitute numerical values and evaluate *L*:

$$L = \frac{(5\,\text{s})^2(9.81\,\text{m/s}^2)}{4\pi^2} = \boxed{6.21\,\text{m}}$$

61 •

Picture the Problem We can find the period of the pendulum from $T = 2\pi\sqrt{L/g_{\text{moon}}}$ where $g_{\text{moon}} = \frac{1}{6}g$ and $L = 6.21$ m.

Express the period of a simple pendulum:

$$T = 2\pi\sqrt{\frac{L}{g_{\text{moon}}}}$$

Substitute numerical values and evaluate *T*:

$$T = 2\pi\sqrt{\frac{6.21\,\text{m}}{\frac{1}{6}(9.81\,\text{m/s}^2)}} = \boxed{12.2\,\text{s}}$$

62 •

Picture the Problem We can find the value of g at the location of the pendulum by solving the equation $T = 2\pi\sqrt{L/g}$ for g and evaluating it for the given length and period.

Express the period of a simple pendulum:

$$T = 2\pi\sqrt{\frac{L}{g}}$$

Solve for g:

$$g = \frac{4\pi^2 L}{T^2}$$

Substitute numerical values and evaluate g:

$$g = \frac{4\pi^2(0.7\,\text{m})}{(1.68\,\text{s})^2} = \boxed{9.79\,\text{m/s}^2}$$

***63** •

Picture the Problem We can use $T = 2\pi\sqrt{L/g}$ to find the period of this pendulum.

Express the period of a simple pendulum:

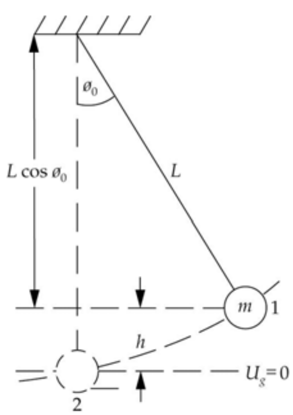
$$T = 2\pi\sqrt{\frac{L}{g}}$$

Substitute numerical values and evaluate T:

$$T = 2\pi\sqrt{\frac{34\,\text{m}}{9.81\,\text{m/s}^2}} = \boxed{11.7\,\text{s}}$$

64 ••

Picture the Problem The figure shows the simple pendulum at maximum angular displacement ϕ_0. The total energy of the simple pendulum is equal to its initial gravitational potential energy. We can apply the definition of gravitational potential energy and use the small-angle approximation to show that $E \approx \frac{1}{2}mgL\phi_0^2$.



Express the total energy of the simple pendulum at maximum displacement:

$$E = U_{\text{max displacement}} = mgh = mgL[1 - \cos\phi_0]$$

For $\phi << 1$:

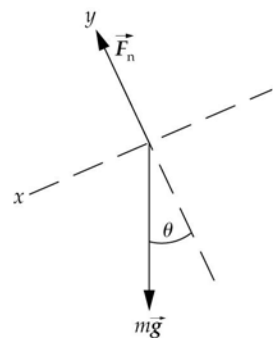
$$\cos\phi \approx 1 - \tfrac{1}{2}\phi^2$$

Substitute and simplify to obtain:

$$E = mgL\left[1-\left(1-\tfrac{1}{2}\phi_0^2\right)\right] = \boxed{\tfrac{1}{2}mgL\phi_0^2}$$

65 ••

Picture the Problem Because the cart is accelerating down the incline, the period of the simple pendulum will be given by $T = 2\pi\sqrt{L/g_{\text{eff}}}$ where g_{eff} is less than g by the acceleration of the cart. We can apply Newton's 2nd law to the cart to find its acceleration down the incline and then subtract this acceleration from g to find g_{eff}.



Express the period of a simple pendulum in terms of its length and the effective value of the acceleration of gravity:

$$T = 2\pi\sqrt{\frac{L}{g_{\text{eff}}}}$$

Relate g_{eff} to the acceleration of the cart:

$$g_{\text{eff}} = g - a$$

Apply $\sum F_x = ma_x$ to the cart and solve for its acceleration:

$$mg\sin\theta = ma$$

and

$$a = g\sin\theta$$

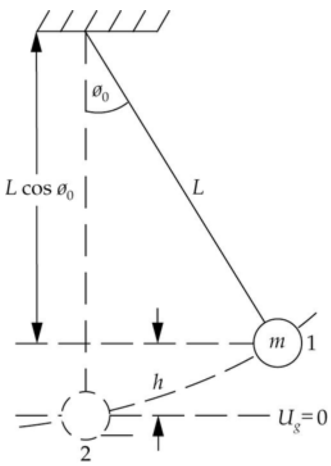
Substitute to obtain:

$$T = 2\pi\sqrt{\frac{L}{g-a}} = 2\pi\sqrt{\frac{L}{g-g\sin\theta}}$$

$$= \boxed{2\pi\sqrt{\frac{L}{g(1-\sin\theta)}}}$$

66 ••

Picture the Problem The figure shows the simple pendulum at maximum angular displacement ϕ_0. We can express the angular position of the pendulum's bob in terms of its initial angular position and time and differentiate this expression to find the maximum speed of the bob. We can use conservation of energy to find an exact value for v_{max} and the approximation $\cos\phi \approx 1 - \frac{1}{2}\phi^2$ to show that this value reduces to the former value for small ϕ.



(*a*) Relate the speed of the pendulum's bob to its angular speed:

$$v = L\frac{d\phi}{dt} \qquad (1)$$

Express the angular position of the pendulum as a function of time:

$$\phi = \phi_0 \cos\omega t$$

Differentiate this expression to express the angular speed of the pendulum:

$$\frac{d\phi}{dt} = -\phi_0\omega\sin\omega t$$

Substitute in equation (1) to obtain:

$$v = -L\phi_0\omega\sin\omega t = -v_{max}\sin\omega t$$

Simplify v_{max} to obtain:

$$v_{max} = L\phi_0\sqrt{\frac{g}{L}} = \boxed{\phi_0\sqrt{gL}}$$

(*b*) Use conservation of energy to relate the potential energy of the pendulum at point 1 to its kinetic energy at point 2:

$$\Delta K + \Delta U = 0$$

or, because $K_1 = U_2 = 0$,

$$K_2 - U_1 = 0$$

Substitute for K_2 and U_1:

$$\tfrac{1}{2}mv_2^2 - mgh = 0$$

Express h in terms of L and ϕ_0:

$$h = L(1-\cos\phi_0)$$

Substitute for h and solve for $v_2 = v_{max}$ to obtain:

$$v_{max} = \boxed{\sqrt{2gL(1-\cos\phi_0)}} \qquad (2)$$

(*c*) For $\phi_0 << 1$: $1-\cos\phi_0 \approx \frac{1}{2}\phi_0^2$

Substitute in equation (2) to obtain:

$$v_{\max} = \sqrt{2gL\left(\tfrac{1}{2}\phi_0^2\right)} = \boxed{\phi_0\sqrt{gL}}$$

in agreement with our result in part (*a*).

(*d*) Express the difference in the results from (*a*) and (*b*):

$$\Delta v = v_{\max,a} - v_{\max,b} \qquad (3)$$

Using ϕ_0 = 0.20 rad and L = 1 m, evaluate the result in (*b*):

$$v_{\max,b} = \sqrt{2\left(9.81\,\text{m/s}^2\right)(1\,\text{m})(1-\cos 0.2)} = 0.6254\,\text{m/s}$$

Using ϕ_0 = 0.20 rad and L = 1 m, evaluate the result in part (*a*):

$$v_{\max.a} = (0.20\,\text{rad})\sqrt{\left(9.81\,\text{m/s}^2\right)(1\,\text{m})} = 0.6264\,\text{m/s}$$

Substitute in equation (3) to obtain:

$$\Delta v = 0.6264\,\text{m/s} - 0.6254\,\text{m/s} = 0.001\,\text{m/s} = \boxed{1.00\,\text{mm/s}}$$

Physical Pendulums

67 •

Picture the Problem The period of this physical pendulum is given by $T = 2\pi\sqrt{I/MgD}$ where I is the moment of inertia of the thin disk with respect to an axis through its pivot point. We can use the parallel-axis theorem to express I in terms of the moment of inertia of the disk with respect to its center of mass and the distance from its center of mass to its pivot point.

Express the period of physical pendulum:

$$T = 2\pi\sqrt{\frac{I}{MgD}}$$

Using the parallel-axis theorem, find the moment of inertia of the thin disk about an axis through the pivot point:

$$I = I_{\text{cm}} + MR^2 = \tfrac{1}{2}MR^2 + MR^2 = \tfrac{3}{2}MR^2$$

Substitute to obtain:

$$T = 2\pi\sqrt{\frac{\tfrac{3}{2}MR^2}{MgR}} = 2\pi\sqrt{\frac{3R}{2g}}$$

Substitute numerical values and evaluate T:

$$T = 2\pi\sqrt{\frac{3(0.2\,\text{m})}{2\left(9.81\,\text{m/s}^2\right)}} = \boxed{1.10\,\text{s}}$$

68 •

Picture the Problem The period of this physical pendulum is given by $T = 2\pi\sqrt{I/MgD}$ where I is the moment of inertia of the circular hoop with respect to an axis through its pivot point. We can use the parallel-axis theorem to express I in terms of the moment of inertia of the hoop with respect to its center of mass and the distance from its center of mass to its pivot point.

Express the period of the physical pendulum:

$$T = 2\pi\sqrt{\frac{I}{MgD}}$$

Using the parallel-axis theorem, find the moment of inertia of the circular hoop about an axis through the pivot point:

$$I = I_{\text{cm}} + MR^2 = MR^2 + MR^2 = 2MR^2$$

Substitute to obtain:

$$T = 2\pi\sqrt{\frac{2MR^2}{MgR}} = 2\pi\sqrt{\frac{2R}{g}}$$

Substitute numerical values and evaluate T:

$$T = 2\pi\sqrt{\frac{2(0.5\,\text{m})}{9.81\,\text{m/s}^2}} = \boxed{2.01\,\text{s}}$$

69 •

Picture the Problem The period of a physical pendulum is given by $T = 2\pi\sqrt{I/MgD}$ where I is its moment of inertia with respect to an axis through its pivot point. We can solve this equation for I and evaluate it using the given numerical data.

Express the period of the physical pendulum:

$$T = 2\pi\sqrt{\frac{I}{MgD}}$$

Solve for I:

$$I = \frac{MgDT^2}{4\pi^2}$$

Substitute numerical values and evaluate I:

$$I = \frac{(3\,\text{kg})(9.81\,\text{m/s}^2)(0.1\,\text{m})(2.6\,\text{s})^2}{4\pi^2} = \boxed{0.504\,\text{kg}\cdot\text{m}^2}$$

***70 ••**

Picture the Problem We can use the expression for the period of a simple pendulum to find the period of the clock.

(*a*) Express the period of a simple pendulum:

$$T = 2\pi\sqrt{\frac{\ell}{g}}$$

Substitute numerical values and evaluate *T*:

$$T = 2\pi\sqrt{\frac{4\,\text{m}}{9.81\,\text{m/s}^2}} = \boxed{4.01\,\text{s}}$$

(*b*) By effectively raising the center of mass of the pendulum, placing coins in the tray shortens the period.

71 ••

Picture the Problem Let *x* be the distance of the pivot from the center of the rod, *m* the mass at each end of the rod, and *L* the length of the rod. We can express the period of the physical pendulum as a function of the distance *x* and then differentiate this expression with respect to *x* to show that, when *x* = *L*/2, the period is a minimum.

(*a*) Express the period of a physical pendulum:

$$T = 2\pi\sqrt{\frac{I}{MgD}} \qquad (1)$$

Express the moment of inertia of the dumbbell with respect to an axis through its center of mass:

$$I_{\text{cm}} = m\left(\frac{L}{2}\right)^2 + m\left(\frac{L}{2}\right)^2 = \tfrac{1}{2}mL^2$$

Using the parallel-axis theorem, express the moment of inertia of the dumbbell with respect to an axis through the pivot point:

$$I = I_{\text{cm}} + 2mx^2 = \tfrac{1}{2}mL^2 + 2mx^2$$

Substitute in equation (1) to obtain:

$$T = 2\pi\sqrt{\frac{\frac{1}{2}mL^2 + 2mx^2}{2mgx}} = \frac{2\pi}{\sqrt{g}}\sqrt{\frac{\frac{1}{4}L^2 + x^2}{x}} \qquad (2)$$

$$= C\sqrt{\frac{\frac{1}{4}L^2 + x^2}{x}}$$

where $C = \dfrac{2\pi}{\sqrt{g}}$

Set $dT/dx = 0$ to find the condition for minimum T:

$$\frac{dT}{dx} = C \cdot \frac{d}{dx}\sqrt{\frac{\frac{1}{4}L^2 + x^2}{x}} = 0 \text{ for extrema}$$

Evaluate the derivative to obtain:

$$\frac{2x^2 - \left(\frac{1}{4}L^2 + x^2\right)}{x^2\sqrt{\frac{\frac{1}{4}L^2 + x^2}{x}}} = 0$$

Because the denominator of this expression cannot be zero, it must be true that:

$$2x^2 - \left(\frac{1}{4}L^2 + x^2\right) = 0$$

Solve for x to obtain:

$$x = \boxed{\frac{1}{2}L}$$

i.e., the period is a minimum when the pivot point is at one of the masses.

(*b*) Substitute $x = L/4$ in equation (2) and simplify to obtain:

$$T = 2\pi\sqrt{\frac{\frac{1}{4}L^2 + \left(\frac{1}{4}L\right)^2}{\frac{1}{2}gL}} = \pi\sqrt{\frac{5L}{g}}$$

Substitute numerical values and evaluate T:

$$T = \pi\sqrt{\frac{5(2\,\text{m})}{9.81\,\text{m/s}^2}} = \boxed{3.17\,\text{s}}$$

Remarks: In (*a*), we've shown that $x = L/2$ corresponds to an *extreme* value; i.e., to either a maximum or a minimum. To complete the demonstration that this value of x corresponds to a minimum, we can either (1) show that d^2T/dx^2 evaluated at $x = L/2$ is positive, or (2) graph T as a function of x and note that the graph is a minimum at $x = L/2$.

72 ••

Picture the Problem Let x be the distance of the pivot from the center of the rod. We'll express the period of the physical pendulum as a function of the distance x and then differentiate this expression with respect to x to find the location of the pivot point that minimizes the period of the physical pendulum.

Express the period of a physical pendulum:

$$T = 2\pi\sqrt{\frac{I}{MgD}} \qquad (1)$$

Express the moment of inertia of the dumbbell with respect to an axis through its center of mass:

$$I_{\text{cm}} = m\left(\frac{L}{2}\right)^2 + m\left(\frac{L}{2}\right)^2 + \tfrac{1}{12}(2m)L^2 = \tfrac{2}{3}mL^2$$

Using the parallel-axis theorem, express the moment of inertia of the dumbbell with respect to an axis through the pivot point:

$$I = I_{\text{cm}} + 4mx^2 = \tfrac{2}{3}mL^2 + 4mx^2$$

Substitute in equation (1) to obtain:

$$T = 2\pi\sqrt{\frac{\tfrac{2}{3}mL^2 + 4mx^2}{4mgx}} = \frac{\pi}{\sqrt{g}}\sqrt{\frac{\tfrac{2}{3}L^2 + 4x^2}{x}}$$

or

$$T = C\sqrt{\frac{\tfrac{2}{3}L^2 + 4x^2}{x}} \text{ where } C = \frac{\pi}{\sqrt{g}}$$

Set $dT/dx = 0$ to find the condition for minimum T:

$$\frac{dT}{dx} = C \times \frac{d}{dx}\sqrt{\frac{\tfrac{2}{3}L^2 + 4x^2}{x}} = 0 \text{ for extrema}$$

Evaluate the derivative to obtain:

$$\frac{8x^2 - \left(\tfrac{2}{3}L^2 + 4x^2\right)}{2x^2\sqrt{\frac{\tfrac{2}{3}L^2 + 4x^2}{x}}} = 0$$

Because the denominator of this expression cannot be zero, it follows that:

$$8x^2 - \left(\tfrac{2}{3}L^2 + 4x^2\right) = 0$$

Solve for x to obtain:

$$x = \frac{L}{\sqrt{6}}$$

The distance to the pivot point from the nearer mass is:

$$d = \frac{L}{2} - \frac{L}{\sqrt{6}} = \boxed{0.0918L}$$

Remarks: We've shown that $x = L/\sqrt{6}$ corresponds to an *extreme* value; i.e., to either a maximum or a minimum. To complete the demonstration that this value of x corresponds to a minimum, we can either (1) show that d^2T/dx^2 evaluated at

$x = L/\sqrt{6}$ is positive, or (2) graph T as a function of x and note that the graph is a minimum at $x = L/\sqrt{6}$.

***73 ••**

Picture the Problem Let *x* be the distance of the pivot from the center of the meter stick, *m* the mass of the meter stick, and *L* its length. We'll express the period of the meter stick as a function of the distance *x* and then differentiate this expression with respect to *x* to determine where the hole should be drilled to minimize the period.

Express the period of a physical pendulum:

$$T = 2\pi\sqrt{\frac{I}{MgD}} \qquad (1)$$

Express the moment of inertia of the meter stick with respect to its center of mass:

$$I_{\text{cm}} = \tfrac{1}{12}mL^2$$

Using the parallel-axis theorem, express the moment of inertia of the meter stick with respect to the pivot point:

$$I = I_{\text{cm}} + mx^2 = \tfrac{1}{12}mL^2 + mx^2$$

Substitute in equation (1) to obtain:

$$T = 2\pi\sqrt{\frac{\frac{1}{12}mL^2 + mx^2}{mgx}} = \frac{2\pi}{\sqrt{g}}\sqrt{\frac{\frac{1}{12}L^2 + x^2}{x}} = C\sqrt{\frac{\frac{1}{12}L^2 + x^2}{x}}$$

where $C = \dfrac{2\pi}{\sqrt{g}}$

Set $dT/dx = 0$ to find the condition for minimum T:

$$\frac{dT}{dx} = C \times \frac{d}{dx}\sqrt{\frac{\frac{1}{12}L^2 + x^2}{x}} = 0 \text{ for extrema}$$

Evaluate the derivative to obtain:

$$\frac{2x^2 - \left(\frac{1}{12}L^2 + x^2\right)}{x^2\sqrt{\frac{\frac{1}{12}L^2 + x^2}{x}}} = 0$$

Because the denominator of this expression cannot be zero, it follows

$$2x^2 - \left(\tfrac{1}{12}L^2 + x^2\right) = 0$$

that:

Solve for and evaluate x to obtain:

$$x = \frac{L}{\sqrt{12}} = \frac{100\,\text{cm}}{\sqrt{12}} = 28.9\,\text{cm}$$

The hole should be drilled at a distance:

$$d = 50\,\text{cm} - 28.9\,\text{cm} = \boxed{21.1\,\text{cm}}$$

from the center of the meter stick.

74 ••

Picture the Problem Let *m* represent the mass and *r* the radius of the uniform disk. We'll use the expression for the period of a physical pendulum and the parallel-axis theorem to obtain a quadratic equation that we can solve for *d*. We will then treat our expression for the period of the pendulum as an extreme-value problem, setting its derivative equal to zero in order to determine the value for *d* that will minimize the period.

(*a*) Express the period of a physical pendulum:

$$T = 2\pi\sqrt{\frac{I}{mgd}}$$

Using the parallel-axis theorem, relate the moment of inertia with respect to an axis through the hole to the moment of inertia with respect to the disk's center of mass:

$$I = I_{\text{cm}} + md^2 = \tfrac{1}{2}mR^2 + md^2$$

Substitute to obtain:

$$T = 2\pi\sqrt{\frac{\frac{1}{2}mR^2 + md^2}{mgd}} = 2\pi\sqrt{\frac{\frac{1}{2}R^2 + d^2}{gd}} \qquad (1)$$

Square both sides of this equation, simplify, and substitute numerical values to obtain:

$$d^2 - \frac{gT^2}{4\pi^2}d + \frac{R^2}{2} = 0$$

or

$$d^2 - (1.553\,\text{m})d + 0.320\,\text{m}^2 = 0$$

Solve the quadratic equation to obtain:

$$d = \boxed{0.245\,\text{m}}$$

The second root, $d = 1.31$ m, is too large to be physically meaningful.

(*b*) Set the derivative of equation (1) equal to zero to find relative maxima and minima:

$$\frac{dT}{dd}=\frac{2\pi}{\sqrt{g}}\cdot\frac{d}{dd}\sqrt{\frac{\frac{1}{2}R^2+d^2}{d}}$$
$$=0\text{ for extrema}$$

Evaluate the derivative to obtain:

$$\frac{2d^2-\left(\frac{1}{2}R^2+d^2\right)}{2d^2\sqrt{\frac{\frac{1}{2}R^2+d^2}{d}}}=0$$

Because the denominator of this fraction cannot be zero:

$$2d^2-\left(\frac{1}{2}R^2+d^2\right)=0$$

Solve this equation to obtain:

$$d=\boxed{\frac{R}{\sqrt{2}}}$$

Evaluate equation (1) with $d=R/\sqrt{2}$ to obtain an expression for the shortest possible period of this physical pendulum:

$$T=2\pi\sqrt{\frac{\frac{1}{2}R^2+\frac{1}{2}R^2}{g\frac{R}{\sqrt{2}}}}=2\pi\sqrt{\frac{\sqrt{2}R}{g}}$$

Substitute numerical values and evaluate *T*:

$$T=2\pi\sqrt{\frac{\sqrt{2}(0.8\,\text{m})}{9.81\,\text{m/s}^2}}=\boxed{2.13\,\text{s}}$$

Remarks: We've shown that $d=R/\sqrt{2}$ corresponds to an *extreme* value; i.e., to either a maximum or a minimum. To complete the demonstration that this value of *d* corresponds to a minimum, we can either (1) show that d^2T/dd^2 evaluated at $d=R/\sqrt{2}$ is positive, or (2) graph *T* as a function of *d* and note that the graph is a minimum at $d=R/\sqrt{2}$.

75 •••

Picture the Problem We can use the equation for the period of a physical pendulum and the parallel-axis theorem to show that $h_1+h_2=gT^2/4\pi^2$.

Express the period of the physical pendulum:

$$T=2\pi\sqrt{\frac{I}{mgd}}$$

Using the parallel-axis theorem, relate the moment of inertia with respect to an axis through P_1 to the

$$I=I_{\text{cm}}+mh_1^2$$

moment of inertia with respect to the disk's center of mass:

Substitute to obtain:

$$T = 2\pi\sqrt{\frac{I_{\text{cm}} + mh_1^2}{mgh_1}}$$

Square both sides of this equation and rearrange to obtain:

$$\frac{mgT^2}{4\pi^2} = \frac{I_{\text{cm}}}{h_1} + mh_1 \qquad (1)$$

Because the period of oscillation is the same for point P_2:

$$\frac{I_{\text{cm}}}{h_1} + mh_1 = \frac{I_{\text{cm}}}{h_2} + mh_2$$

Solve this equation for I_{cm}:

$$I_{\text{cm}} = mh_1h_2$$

Substitute in equation (1) to obtain:

$$\frac{mgT^2}{4\pi^2} = \frac{mh_1h_2}{h_1} + mh_1$$

or

$$\boxed{h_2 + h_1 = \frac{gT^2}{4\pi^2}}$$

76 •••

Picture the Problem We can find the period of the physical pendulum in terms of the period of a simple pendulum by starting with $T = 2\pi\sqrt{I/mgL}$ and applying the parallel-axis theorem. Performing a binomial expansion for $r << L$ on the radicand of our expression for T will lead to $T \approx T_0(1 + r^2/5L^2)$.

(a) Express the period of the physical pendulum:

$$T = 2\pi\sqrt{\frac{I}{mgL}}$$

Using the parallel-axis theorem, relate the moment of inertia of the pendulum about an axis through its center of mass to its moment of inertia with respect to an axis through its point of support:

$$I = I_{\text{cm}} + mL^2 = \tfrac{2}{5}mr^2 + mL^2$$

Substitute and simplify to obtain:

$$T = 2\pi\sqrt{\frac{\frac{2}{5}mr^2 + mL^2}{mgL}} = 2\pi\sqrt{\frac{\frac{2}{5}r^2 + L^2}{gL}}$$

$$= 2\pi\sqrt{\frac{L}{g}\left(1+\frac{2r^2}{5L^2}\right)} = 2\pi\sqrt{\frac{L}{g}}\sqrt{1+\frac{2r^2}{5L^2}}$$

$$= \boxed{T_0\sqrt{1+\frac{2r^2}{5L^2}}}$$

(*b*) Using the binomial expansion, expand $\left(1+\frac{2r^2}{5L^2}\right)^{1/2}$:

$$\left(1+\frac{2r^2}{5L^2}\right)^{1/2} = 1+\frac{1}{2}\left(\frac{2r^2}{5L^2}\right)+\frac{1}{8}\left(\frac{2r^2}{5L^2}\right)^2 + \text{higher-order terms}$$

$$\approx 1+\frac{r^2}{5L^2}$$

provided $r << L$

Substitute in our result from (*a*) to obtain:

$$T \approx \boxed{T_0\left(1+\frac{r^2}{5L^2}\right)}$$

(*c*) Express the fractional error when the approximation $T = T_0$ is used for this pendulum:

$$\frac{\Delta T}{T} \approx \frac{T - T_0}{T_0} = \frac{T}{T_0} - 1$$

$$= 1 + \frac{r^2}{5L^2} - 1 = \frac{r^2}{5L^2}$$

Substitute numerical values and evaluate $\Delta T/T$:

$$\frac{\Delta T}{T} \approx \frac{(2\,\text{cm})^2}{5(100\,\text{cm})^2} = \boxed{0.008\%}$$

For an error of 1%:

$$\frac{r^2}{5L^2} = 0.01$$

Solve for and evaluate r with L = 100 cm:

$$r = L\sqrt{0.05} = (100\,\text{cm})\sqrt{0.05}$$

$$= \boxed{22.4\,\text{cm}}$$

77 •••

Picture the Problem The period of this physical pendulum is given by $T = 2\pi\sqrt{I/MgD}$. We can express its period as a function of the distance d by using the definition of the center of mass of the pendulum to find D in terms of d and the parallel-axis theorem to express I in terms of d. Solving the resulting quadratic equation yields d.

In (*b*), because the clock is losing 5 minutes per day, one would reposition the disk so that the clock runs faster; i.e., so the pendulum has a shorter period. We can determine the appropriate correction to make in the position of the disk by relating the fractional time loss to the fractional change in its position.

(*a*) Express the period of the physical pendulum:

$$T = 2\pi\sqrt{\frac{I}{m_{\text{tot}}gx_{\text{cm}}}}$$

Solve for $\frac{I}{x_{\text{cm}}}$:

$$\frac{I}{x_{\text{cm}}} = \frac{T^2 g m_{\text{tot}}}{4\pi^2} \qquad (1)$$

Express the moment of inertia of the physical pendulum, relative to an axis through the pivot point, as a function of *d*:

$$I = I_{\text{cm}} + Md^2 = \tfrac{1}{3}mL^2 + \tfrac{1}{2}Mr^2 + Md^2$$

Substitute numerical values and evaluate *I*:

$$\begin{aligned} I &= \tfrac{1}{3}(0.8\,\text{kg})(2\,\text{m})^2 + \tfrac{1}{2}(1.2\,\text{kg})(0.15\,\text{m})^2 \\ &\quad + (1.2\,\text{kg})d^2 \\ &= 1.0802\,\text{kg}\cdot\text{m}^2 + (1.2\,\text{kg})d^2 \end{aligned}$$

Locate the center of mass of the physical pendulum relative to the pivot point:

$$(2\,\text{kg})x_{\text{cm}} = (0.8\,\text{kg})(1\,\text{m}) + (1.2\,\text{kg})d$$

and

$$x_{\text{cm}} = 0.4\,\text{m} + 0.6d$$

Substitute in equation (1) to obtain:

$$\frac{1.0802\,\text{kg}\cdot\text{m}^2 + (1.2\,\text{kg})d^2}{0.4\,\text{m} + 0.6d} = \frac{T^2(9.81\,\text{m/s}^2)(2\,\text{kg})}{4\pi^2} = (0.49698\,\text{kg}\cdot\text{m/s}^2)T^2 \qquad (2)$$

Setting $T = 2.5$ s and solving for *d* yields:

$$d = \boxed{1.63572\,\text{m}}$$

where we have kept more than three significant figures for use in part (*b*).

(*b*) There are 1440 minutes per day. If the clock loses 5 minutes per day, then the period of the clock is related to the perfect period of the clock by:

$$1435T = 1440T_{\text{perfect}}$$

where $T_{\text{perfect}} = 3.5$ s.

Solve for and evaluate T:

$$T = \frac{1440}{1435} T_{\text{perfect}} = \frac{1440}{1435}(3.5\,\text{s}) = 3.51220\,\text{s}$$

Substitute $T = 3.51220$ s in equation (2) and solve for d to obtain:

$$d = 3.40140\,\text{m}$$

Substitute $T = 3.50$ s in equation (2) and solve for d' to obtain:

$$d' = 3.37825\,\text{m}$$

Express the distance the disk needs to be moved upward to correct the period:

$$\Delta d = d - d' = 3.40140\,\text{m} - 3.37825\,\text{m} = \boxed{2.32\,\text{cm}}$$

***78 ••**

Picture the Problem The period of a simple pendulum depends on its amplitude ϕ_0 according to $T = 2\pi\sqrt{\frac{L}{g}}\left[1 + \frac{1}{2^2}\sin^2\frac{1}{2}\phi_0 + \frac{1}{2^2}\left(\frac{3}{4}\right)^2\sin^4\frac{1}{2}\phi_0 + \ldots\right]$. We can approximate T to the second-order term and express $\Delta T/T = (T_{\text{slow}} - T_{\text{accurate}})/T$. Equating this expression to $\Delta T/T$ calculated from the fractional daily loss of time will allow us to solve for and evaluate the amplitude of the pendulum that corresponds to keeping perfect time.

Express the fractional daily loss of time:

$$\frac{\Delta T}{T} = \frac{48\,\text{s}}{\text{day}} \times \frac{1\,\text{day}}{24\,\text{h}} \times \frac{1\,\text{h}}{3600\,\text{s}} = \frac{48}{86400}$$

Approximate the period of the clock to the second-order term:

$$T = 2\pi\sqrt{\frac{L}{g}}\left[1 + \frac{1}{2^2}\sin^2\frac{1}{2}\phi_0\right]$$

Express the difference in the periods of the slow and accurate clocks:

$$\begin{aligned}\Delta T &= T_{\text{slow}} - T_{\text{accurate}} \\ &= 2\pi\sqrt{\frac{L}{g}}\left\{\left[1 + \frac{1}{2^2}\sin^2\frac{1}{2}(8.4°)\right] - \left[1 + \frac{1}{2^2}\sin^2\frac{1}{2}\phi_0\right]\right\} \\ &= 2\pi\sqrt{\frac{L}{g}}\left[\frac{1}{2^2}\sin^2\frac{1}{2}(8.4°) - \frac{1}{2^2}\sin^2\frac{1}{2}\phi_0\right]\end{aligned}$$

Divide both sides of this equation by T to obtain:

$$\frac{\Delta T}{T}=\frac{1}{4}\sin^2 4.2°-\frac{1}{4}\sin^2\frac{1}{2}\phi_0$$

Substitute for $\frac{\Delta T}{T}$ and simplify to obtain:

$$\frac{1}{4}\sin^2 4.2°-\frac{1}{4}\sin^2\frac{1}{2}\phi_0=\frac{48}{86400}$$

and

$$\sin\frac{1}{2}\phi_0=0.05605$$

Solve for ϕ_0:

$$\phi_0=\boxed{6.43°}$$

79 ••

Picture the Problem The period of a simple pendulum depends on its amplitude ϕ_0 according to $T=2\pi\sqrt{\frac{L}{g}}\left[1+\frac{1}{2^2}\sin^2\frac{1}{2}\phi_0+\frac{1}{2^2}\left(\frac{3}{4}\right)^2\sin^4\frac{1}{2}\phi_0+...\right]$. We'll approximate T to the second-order term and express $\Delta T/T=(T_{slow}-T_{correct})/T$. Equating this expression to $\Delta T/T$ calculated from the fractional daily loss of time will allow us to solve for and evaluate the amplitude of the pendulum that corresponds to keeping correct time.

Express the fractional daily loss of time:

$$\frac{\Delta T}{T}=\frac{5\,\text{min}}{\text{day}}\times\frac{1\,\text{day}}{24\,\text{h}}\times\frac{1\,\text{h}}{60\,\text{min}}=\frac{5}{1440}$$

Approximate the period of the clock to the second-order term:

$$T=2\pi\sqrt{\frac{L}{g}}\left[1+\frac{1}{2^2}\sin^2\frac{1}{2}\phi_0\right]$$

Assuming that the amplitude of the slow-running clock's pendulum is small enough to ignore, express the difference in the periods of the slow and corrected clocks:

$$\begin{aligned}\Delta T&=T_{slow}-T_{correct}\\&=2\pi\sqrt{\frac{L}{g}}\left\{1-\left[1+\frac{1}{2^2}\sin^2\frac{1}{2}\phi_0\right]\right\}\\&=2\pi\sqrt{\frac{L}{g}}\left[-\frac{1}{2^2}\sin^2\frac{1}{2}\phi_0\right]\end{aligned}$$

Divide both sides of this expression by T to obtain:

$$\frac{\Delta T}{T}=-\frac{1}{4}\sin^2\frac{1}{2}\phi_0$$

Substitute for $\frac{\Delta T}{T}$ and simplify to obtain:

$$-\frac{1}{4}\sin^2\frac{1}{2}\phi_0=\frac{-5}{1440}$$

and

$$\sin\frac{1}{2}\phi_0 = 0.1178$$

Solve for ϕ_0: $\phi_0 = \boxed{13.5°}$

Damped Oscillations

80 •

Picture the Problem We can use the definition of the damping constant and its dimensions to show that it has units of kg/s.

Using its definition, relate the decay constant τ to the damping constant b:

$$\tau = \frac{m}{b} \Rightarrow b = \frac{m}{\tau}$$

Substitute the units of m and τ to obtain:

$$\text{Dimensionally, } b = \frac{[M]}{[T]} = \boxed{\frac{\text{kg}}{\text{s}}}$$

81 •

Picture the Problem For small damping, $Q = \dfrac{2\pi}{\left(|\Delta E|/E\right)_{\text{cycle}}}$ where $\Delta E/E$ is the fractional energy loss per cycle.

Relate the Q factor to the fractional energy loss per cycle:

$$Q = \frac{2\pi}{\left(|\Delta E|/E\right)_{\text{cycle}}}$$

Solve for and evaluate the fractional energy loss per cycle:

$$\left(|\Delta E|/E\right)_{\text{cycle}} = \frac{2\pi}{Q} = \frac{2\pi}{200} = \boxed{3.14\%}$$

82 •

Picture the Problem We can find the period of the oscillator from $T = 2\pi\sqrt{m/k}$ and its total initial energy from $E_0 = \frac{1}{2}kA^2$. The Q factor can be found from its definition $Q = 2\pi/\left(|\Delta E|/E\right)_{\text{cycle}}$ and the damping constant from $Q = \omega_0 m/b$.

(*a*) The period of the oscillator is given by:

$$T = 2\pi\sqrt{\frac{m}{k}}$$

Substitute numerical values and evaluate T:

$$T = 2\pi\sqrt{\frac{2\,\text{kg}}{400\,\text{N/m}}} = \boxed{0.444\,\text{s}}$$

(*b*) Relate the initial energy of the

$$E_0 = \tfrac{1}{2}kA^2$$

oscillator to its amplitude:

Substitute numerical values and evaluate E_0:

$$E_0 = \tfrac{1}{2}(400\,\text{N/m})(0.03\,\text{m})^2 = \boxed{0.180\,\text{J}}$$

(*c*) Relate the fractional rate at which the energy decreases to the Q value and evaluate Q:

$$Q = \frac{2\pi}{(|\Delta E|/E)_{\text{cycle}}} = \frac{2\pi}{0.01} = \boxed{628}$$

Express the Q value in terms of b:

$$Q = \frac{\omega_0 m}{b}$$

Solve for the damping constant b:

$$b = \frac{\omega_0 m}{Q} = \frac{2\pi m}{TQ}$$

Substitute numerical values and evaluate b:

$$b = \frac{2\pi(2\,\text{kg})}{(0.444\,\text{s})(628)} = \boxed{0.0451\,\text{kg/s}}$$

83 ••

Picture the Problem The amplitude of the oscillation at time t is $A(t) = A_0 e^{-t/2\tau}$ where $\tau = m/b$ is the decay constant. We'll express the amplitudes one period apart and then show that their ratio is constant.

Relate the amplitude of a given oscillation peak to the time at which the peak occurs:

$$A(t) = A_0 e^{-t/2\tau}$$

Express the amplitude of the oscillation peak at $t' = t + T$:

$$A(t+T) = A_0 e^{-(t+T)/2\tau}$$

Express the ratio of these consecutive peaks:

$$\frac{A(t)}{A(t+T)} = \frac{A_0 e^{-t/2\tau}}{A_0 e^{-(t+T)/2\tau}} = e^{-T/2\tau} = \boxed{\text{constant}}$$

84 ••

Picture the Problem We can relate the fractional change in the energy of the oscillator each cycle to the fractional change in its amplitude. Both the Q value and the decay constant τ can be found from their definitions.

(*a*) Relate the energy of the oscillator to its amplitude:

$$E = \tfrac{1}{2}kA^2$$

Take the differential of this relationship to obtain:

$$dE = kAdA$$

Divide both sides of this equation by E:

$$\frac{dE}{E} = \frac{kAdA}{\frac{1}{2}kA^2} = 2\frac{dA}{A}$$

Approximate dE and dA by ΔE and ΔA and evaluate $\Delta E/E$:

$$\frac{\Delta E}{E} = 2(5\%) = \boxed{10\%}$$

(*b*) For small damping:

$$\frac{|\Delta E|}{E} = \frac{T}{\tau}$$

and

$$\tau = \frac{T}{|\Delta E|/E} = \frac{3\,\text{s}}{0.01} = \boxed{30\,\text{s}}$$

(*c*) Using its definition, express and evaluate Q:

$$A = \omega_0\tau = \frac{2\pi}{T}\tau = \frac{2\pi}{3\,\text{s}}(30\,\text{s}) = \boxed{62.8}$$

85 ••

Picture the Problem We can use the physical interpretation of Q for small damping $Q = \frac{2\pi}{\left(|\Delta E|/E\right)_{\text{cycle}}}$ to find the fractional decrease in the energy of the oscillator each cycle.

(*a*) Express the fractional decrease in energy each cycle as a function of the Q factor and evaluate $|\Delta E|/E$:

$$\frac{|\Delta E|}{E} = \frac{2\pi}{Q} = \frac{2\pi}{20} = \boxed{0.314}$$

(*b*) Using the definition of the Q factor, use Equation 14-35 to express ω' as a function of Q:

$$\omega' = \omega_0\left[1 - \frac{1}{4}\left(\frac{b^2}{m^2\omega_0^2}\right)\right]^{1/2}$$

$$= \omega_0\left[1 - \frac{1}{4Q^2}\right]^{1/2}$$

Use the approximation $(1 + x)^{½} \approx 1 + ½x$ for small x to obtain:

$$\omega' = \omega_0\left[1 - \frac{1}{8Q^2}\right]$$

Express and evaluate $\omega' - \omega_0$:

$$\omega' - \omega_0 = \omega_0\left[1 - \frac{1}{8Q^2}\right] - \omega_0 = -\frac{1}{8Q^2}$$

$$= -\frac{1}{8(20)^2}$$

$$= \boxed{-3.13\times10^{-2}\,\text{percent}}$$

86 ••

Picture the Problem The amplitude of the spring-and-mass oscillator varies with time according to $A = A_0 e^{-t/2\tau}$ and its energy according to $E = E_0 e^{-t/\tau}$.

(*a*) Express the amplitude of the oscillations as a function of time:

$$A = (6\,\text{cm})e^{-t/4\text{s}}$$

Evaluate the amplitude when t = 2 s:

$$A(2\,\text{s}) = (6\,\text{cm})e^{-2\,\text{s}/4\,\text{s}} = (6\,\text{cm})e^{-1/2}$$

$$= \boxed{3.64\,\text{cm}}$$

Evaluate the amplitude when t = 4 s:

$$A(4\,\text{s}) = (6\,\text{cm})e^{-4\,\text{s}/4\,\text{s}} = (6\,\text{cm})e^{-1}$$

$$= \boxed{2.21\,\text{cm}}$$

(*b*) Express the energy of the system at t = 0:

$$E(0) = E_0 e^{-0/2\,\text{s}} = E_0 = 60\,\text{J}$$

Express the energy in the system at t =2 s:

$$E(2\,\text{s}) = E_0 e^{-2\,\text{s}/2\,\text{s}} = E_0 e^{-1}$$

The energy dissipated in the first 2 s is:

$$\Delta E_{0-2\text{s}} = E(0) - E(2\,\text{s})$$

$$= E_0\left(1 - e^{-1}\right)$$

$$= (60\,\text{J})\left(1 - e^{-1}\right)$$

$$= \boxed{37.9\,\text{J}}$$

The energy dissipated in the second 2-s interval is:

$$\Delta E_{2-4\,\text{s}} = E_{2\,\text{s}}\left(1 - e^{-2\text{s}/2\,\text{s}}\right)$$

$$= (37.9\,\text{J})\left(1 - e^{-1}\right) = \boxed{24.0\,\text{J}}$$

***87** ••

Picture the Problem We can find the fractional loss of energy per cycle from the physical interpretation of Q for small damping. We will also find a general expression for the earth's vibrational energy as a function of the number of cycles it has completed. We can then solve this equation for the earth's vibrational energy after any number of days.

(*a*) Express the fractional change in energy as a function of *Q*:

$$\frac{\Delta E}{E}=\frac{2\pi}{Q}=\frac{2\pi}{400}=\boxed{1.57\%}$$

(*b*) Express the energy of the damped oscillator after one cycle:

$$E_1=E_0\left(1-\frac{\Delta E}{E}\right)$$

Express the energy after two cycles:

$$E_2=E_1\left(1-\frac{\Delta E}{E}\right)=E_0\left(1-\frac{\Delta E}{E}\right)^2$$

Generalizing to *n* cycles:

$$E_n=E_0\left(1-\frac{\Delta E}{E}\right)^n=E_0(1-0.0157)^n$$

$$=\boxed{E_0(0.9843)^n}$$

(*c*) Express 2 d in terms of the number of cycles; i.e., the number of vibrations the earth will have experienced:

$$2\,\text{d}=2\,\text{d}\times\frac{24\,\text{h}}{\text{d}}\times\frac{60\,\text{m}}{\text{h}}$$

$$=2880\,\text{min}\times\frac{1T}{54\,\text{min}}$$

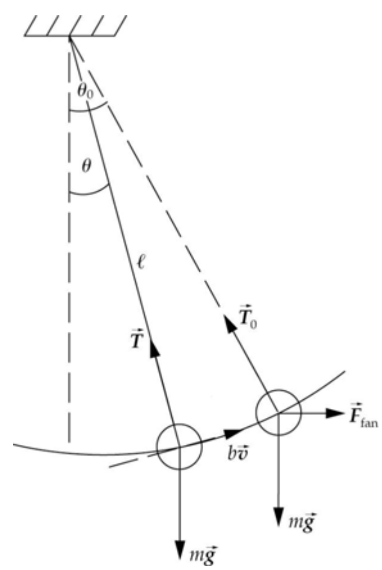
$$=53.3T$$

Evaluate $E(2\text{ d})$:

$$E(2\,\text{d})=E_0(0.9843)^{53.3}=\boxed{0.430E_0}$$

88 ••

Picture the Problem The diagram shows 1) the pendulum bob displaced through an angle θ_0 and held in equilibrium by the force exerted on it by the air from the fan and 2) the bob accelerating, under the influence of gravity, tension force, and drag force, toward its equilibrium position. We can apply Newton's 2nd law to the bob to obtain the differential equation of motion of the damped pendulum and then use its solution to find the decay time constant and the time required for the amplitude of oscillation to decay to 1°.



(*a*) Apply $\sum\tau=I\alpha$ to the pendulum to obtain:

$$-mg\ell\sin\theta+\ell F_{\text{d}}=I\frac{d^2\theta}{dt^2}$$

Express the moment of inertia of the pendulum with respect to an axis through its point of support:

$$I = m\ell^2$$

Substitute for I and F_d to obtain:

$$m\ell^2 \frac{d^2\theta}{dt^2} + \ell bv + mg\ell \sin\theta = 0$$

Because $\theta << 1$ and $v = \ell\omega = \ell d\theta/dt$:

$$m\ell^2 \frac{d^2\theta}{dt^2} + \ell^2 b\frac{d\theta}{dt} + mg\ell\theta = 0$$

or

$$m\frac{d^2\theta}{dt^2} + b\frac{d\theta}{dt} + \frac{mg}{\ell}\theta = 0$$

The solution to this second-order homogeneous differential equation with constant coefficients is:

$$\theta = \theta_0 e^{-t/2\tau}\cos(\omega' t + \delta) \qquad (1)$$

where θ_0 is the maximum amplitude, $\tau = m/b$ is the time constant, and the frequency $\omega' = \omega_0\sqrt{1-(b/2m\omega_0)^2}$.

Apply $\sum \vec{F} = m\vec{a}$ to the bob when it is at its maximum angular displacement to obtain:

$$\sum F_x = F_{\text{fan}} - T\sin\theta_0 = 0$$

and

$$\sum F_y = T\cos\theta_0 - mg = 0$$

Divide the x equation by the y equation to obtain:

$$\frac{F_{\text{fan}}}{mg} = \frac{T\sin\theta_0}{T\cos\theta_0} = \tan\theta_0$$

or

$$F_{\text{fan}} = mg\tan\theta_0$$

When the bob is in equilibrium, the drag force on it equals F_{fan}:

$$bv = mg\tan\theta_0$$

Solve for m/b in the definition of τ to obtain:

$$\tau = \frac{m}{b} = \frac{v}{g\tan\theta_0}$$

Substitute numerical values and evaluate τ:

$$\tau = \frac{7\text{ m/s}}{(9.81\text{ m/s}^2)\tan 5°} = \boxed{8.16\text{ s}}$$

(*b*) From equation (1) we have:

$$\theta = \theta_0 e^{-t/2\tau}$$

When the amplitude has decreased to 1°:

$$5° e^{-t/2\tau} = 1° \text{ or } e^{-t/2\tau} = 0.2$$

Take the natural logarithm of both sides of the equation to obtain:

$$-\frac{t}{2\tau} = \ln(0.2)$$

Solve for t: $t = -2\tau \ln(0.2)$

Substitute for τ and evaluate t: $t = -2(8.16\,\text{s})\ln(0.2) = \boxed{26.3\,\text{s}}$

Driven Oscillations and Resonance

89 •

Picture the Problem The resonant frequency of a vibrating system depends on the mass of the system and on a "stiffness" constant according to $f_0 = \dfrac{1}{2\pi}\sqrt{\dfrac{k}{m}}$ or, in the case of a simple pendulum oscillating with small-amplitude vibrations, $f_0 = \dfrac{1}{2\pi}\sqrt{\dfrac{g}{L}}$.

(*a*) For this spring-and-mass oscillator we have:

$$f_0 = \frac{1}{2\pi}\sqrt{\frac{400\,\text{N/m}}{10\,\text{kg}}} = \boxed{1.01\,\text{Hz}}$$

(*b*) For this spring-and-mass oscillator we have:

$$f_0 = \frac{1}{2\pi}\sqrt{\frac{800\,\text{N/m}}{5\,\text{kg}}} = \boxed{2.01\,\text{Hz}}$$

(*c*) For this simple pendulum we have:

$$f_0 = \frac{1}{2\pi}\sqrt{\frac{9.81\,\text{m/s}^2}{2\,\text{m}}} = \boxed{0.352\,\text{Hz}}$$

90 •

Picture the Problem We can use the physical interpretation of Q for small damping to find the Q factor for this damped oscillator. The width of the resonance curve depends on the Q factor according to $\Delta\omega = \omega_0/Q$.

(*a*) Using the physical interpretation of Q for small damping, relate Q to the fractional loss of energy of the damped oscillator per cycle:

$$Q = \frac{2\pi}{\left(|\Delta E|/E\right)_{\text{cycle}}}$$

Evaluate this expression for $\left(|\Delta E|/E\right)_{\text{cycle}} = 2\%$:

$$Q = \frac{2\pi}{0.02} = \boxed{314}$$

(*b*) Relate the width of the resonance curve to the Q value of the oscillatory system:

$$\Delta\omega = \frac{\omega_0}{Q} = \frac{2\pi f_0}{Q}$$

Substitute numerical values and evaluate $\Delta\omega$:

$$\Delta\omega = \frac{2\pi(300\,\text{s}^{-1})}{3.14} = \boxed{6.00\,\text{rad/s}}$$

91 ••

Picture the Problem The amplitude of the damped oscillations is related to the damping constant, mass of the system, the amplitude of the driving force, and the natural and driving frequencies through $A = \dfrac{F_0}{\sqrt{m^2(\omega_0^2 - \omega^2)^2 + b^2\omega^2}}$. Resonance occurs when $\omega = \omega_0$. At resonance, the amplitude of the oscillations is $A = F_0\big/\sqrt{b^2\omega^2}$ and the width of the resonance curve is related to the damping constant and the mass of the system according to $\Delta\omega = b/m$.

(*a*) Express the amplitude of the oscillations as a function of the driving frequency:

$$A = \frac{F_0}{\sqrt{m^2(\omega_0^2 - \omega^2)^2 + b^2\omega^2}}$$

Determine ω_0:

$$\omega_0 = \sqrt{\frac{k}{m}} = \sqrt{\frac{400\,\text{N/m}}{2\,\text{kg}}} = 14.14\,\text{rad/s}$$

Evaluate the radicand in the expression for *A* to obtain:

$$(2\,\text{kg})^2\left[(14.14\,\text{rad/s})^2 - (10\,\text{rad/s})^2\right]^2 + (2\,\text{kg/s})^2(10\,\text{rad/s})^2 = 4.04\times10^4\,\text{kg}^2/\text{s}^4$$

Substitute numerical values and evaluate *A*:

$$A = \frac{10\,\text{N}}{\sqrt{4.04\times10^4\,\text{kg}^2/\text{s}^4}} = \boxed{4.98\,\text{cm}}$$

(*b*) Resonance occurs when:

$$\omega = \omega_0 = \boxed{14.1\,\text{rad/s}}$$

(*c*) Express the amplitude of the motion at resonance:

$$A = \frac{F_0}{\sqrt{b^2\omega_0^2}}$$

Substitute numerical values and evaluate *A*:

$$A = \frac{10\,\text{N}}{\sqrt{(2\,\text{kg/s})^2(14.14\,\text{rad/s})^2}} = \boxed{35.4\,\text{cm}}$$

(*d*) The width of the resonance curve is:

$$\Delta\omega = \frac{b}{m} = \frac{2\,\text{kg/s}}{2\,\text{kg}} = \boxed{1.00\,\text{rad/s}}$$

92 ••

Picture the Problem We'll find a general expression for the damped oscillator's energy as a function of the number of cycles it has completed. We can then solve this equation for the number of cycles corresponding to the loss of half the oscillator's energy. The Q factor is related to the fractional energy loss per cycle through $\Delta E/E = 2\pi/Q$ and the width of the resonance curve is $\Delta\omega = \omega_0/Q$ where ω_0 is the oscillator's natural angular frequency.

(*a*) Express the energy of the damped oscillator after one cycle:

$$E_1 = E_0\left(1 - \frac{\Delta E}{E}\right)$$

Express the energy after two cycles:

$$E_2 = E_1\left(1 - \frac{\Delta E}{E}\right) = E_0\left(1 - \frac{\Delta E}{E}\right)^2$$

Generalizing to n cycles:

$$E_n = E_0\left(1 - \frac{\Delta E}{E}\right)^n$$

Substitute numerical values:

$$0.5E_0 = E_0(1 - 0.035)^n$$

or

$$0.5 = (0.965)^n$$

Solve for n to obtain:

$$n = \frac{\ln 0.5}{\ln 0.965} = 19.5$$

$$\approx \boxed{20 \text{ complete cycles.}}$$

(*b*) Apply the physical interpretation of Q for small damping to obtain:

$$Q = \frac{2\pi}{\Delta E/E} = \frac{2\pi}{0.035} = \boxed{180}$$

(*c*) The width of the resonance curve is given by:

$$\Delta\omega = \frac{\omega_0}{Q} = \frac{2\pi f_0}{Q} = \frac{2\pi(100\,\text{Hz})}{180}$$

$$= \boxed{3.49\,\text{rad/s}}$$

Collisions

93 •••

Picture the Problem Let the system include the spring-and-mass oscillator and the second object of mass m. Because the net external force acting on this system is zero, momentum is conserved during the collision of the second object with the oscillator.

Because the collision is elastic, we can also apply conservation of energy. Let the subscript 1 refer to the object attached to the spring and the subscript 2 identify the second object.

(*a*) Using momentum conservation, relate the speeds of the objects before and after their collision:

$$mv_{1i} + mv_{2i} = mv_{2f}$$

or

$$v_{1i} + v_{2i} = v_{2f} \qquad (1)$$

Using conservation of energy, obtain a second relationship between the speeds of the objects before and after their collision:

$$\tfrac{1}{2}mv_{1i}^2 + \tfrac{1}{2}mv_{2i}^2 = \tfrac{1}{2}mv_{2f}^2$$

or

$$v_{1i}^2 + v_{2i}^2 = v_{2f}^2 \qquad (2)$$

Solve equation (2) for v_{2i}^2:

$$v_{2i}^2 = v_{2f}^2 - v_{1i}^2 = (v_{2f} + v_{1i})(v_{2f} - v_{1i})$$

Substitute for v_{2f} from equation (1):

$$v_{2i}^2 = (v_{1i} + v_{2i} + v_{1i})(v_{1i} + v_{2i} - v_{1i})$$
$$= (2v_{1i} + v_{2i})(v_{2i}) = 2v_{1i}v_{2i} + v_{2i}^2$$

or

$$2v_{1i}v_{2i} = 0$$

Because $v_{1i} \neq 0$, it follows that:

$$v = v_{2i} = \boxed{0}$$

i.e., the second object must be initially at rest.

(*b*) Because $v_{2i} = 0$, we have, from equation (1):

$$v_{2f} = v_{1i}$$

Because the object connected to the spring was moving through its equilibrium position at the time of collision:

$$v_{1i} = v_{max} = A\omega = (0.1\,\text{m})(40\,\text{s}^{-1})$$
$$= \boxed{4.00\,\text{m/s}}$$

94 •••

Picture the Problem Let the system include the spring-and-mass oscillator and the second object of mass *m*. Because the net external force acting on this system is zero, momentum is conserved during the collision of the second object with the oscillator. Because the collision is elastic, we can also apply conservation of energy. Let the subscript 1 refer to the object attached to the spring and the subscript 2 identify the second object.

Using momentum conservation, relate the speeds of the objects

$$mv_{1i} + mv_{2i} = mv_{2f}$$

or

before and after their collision: $v_{1i} + v_{2i} = v_{2f}$ (1)

Using conservation of energy, obtain a second relationship between the speeds of the objects before and after their collision:

$$\tfrac{1}{2}mv_{1i}^2 + \tfrac{1}{2}mv_{2i}^2 = \tfrac{1}{2}mv_{2f}^2$$

or

$$v_{1i}^2 + v_{2i}^2 = v_{2f}^2 \quad (2)$$

Solve equation (2) for v_{2i}^2:

$$v_{2i}^2 = v_{2f}^2 - v_{1i}^2 = (v_{2f} + v_{1i})(v_{2f} - v_{1i})$$

Substitute for v_{2f} from equation (1):

$$v_{2i}^2 = (v_{1i} + v_{2i} + v_{1i})(v_{1i} + v_{2i} - v_{1i})$$
$$= (2v_{1i} + v_{2i})(v_{2i}) = 2v_{1i}v_{2i} + v_{2i}^2$$

or

$$2v_{1i}v_{2i} = 0$$

Because $v_{1i} \neq 0$, it follows that:

$$v = v_{2i} = 0$$

i.e., the second object must be initially at rest.

Because the object connected to the spring was moving through its equilibrium position at the time of collision:

$$v_{1i} = v_{max} = A\omega = (0.1\,\text{m})(40\,\text{s}^{-1})$$
$$= 4\,\text{m/s}$$

Express the total energy of the system just before the collision:

$$E = \tfrac{1}{2}mv_{1i}^2$$

Solve for *m*:

$$m = \frac{2E}{v_{1i}^2}$$

Substitute numerical values and evaluate *m*:

$$m = \frac{2(8\,\text{J})}{(4\,\text{m/s})^2} = \boxed{1.00\,\text{kg}}$$

Relate the spring constant to the angular frequency of the oscillator:

$$k = m\omega^2$$

Substitute numerical values and evaluate *k*:

$$k = (1\,\text{kg})(40\,\text{s}^{-1})^2 = \boxed{1.60\,\text{kN/m}}$$

95 •••

Picture the Problem Let the system include the spring-and-mass oscillator and the 1-kg object. Because the net external force acting on this system is zero, momentum is conserved during the collision of the second object with the oscillator. Let the subscript 1 refer to the 1-kg object and the subscript 2 to the 2-kg object. We can relate the amplitude of the motion to the maximum speed of the oscillator (which we can find from conservation of momentum) and the angular frequency of the oscillator, which we can determine from its definition. Once we have found the amplitudes and angular frequencies for both collisions, we express the position of each as a function of time, using the initial conditions to find the phase constants.

(*a*) Relate the amplitude of the motion to the angular frequency and maximum speed of the oscillator:

$$A = \frac{v_{\text{max}}}{\omega} \qquad (1)$$

Because the 2-kg object is initially at rest, the maximum speed of the oscillator will be its speed immediately after the collision. Use conservation of momentum to relate this maximum speed to the speed of the 1-kg object before the collision:

$$m_1 v_{1\text{i}} = (m_1 + m_2) v_{\text{max}}$$

Solve for v_{max}:

$$v_{\text{max}} = \frac{m_1}{m_1 + m_2} v_{1\text{i}}$$

Substitute numerical values and evaluate v_{max}:

$$v_{\text{max}} = \frac{1\,\text{kg}}{1\,\text{kg} + 2\,\text{kg}} (6\,\text{m/s}) = 2\,\text{m/s}$$

Express the angular frequency of the oscillator:

$$\omega = \sqrt{\frac{k}{m_1 + m_2}}$$

Substitute numerical values and evaluate ω:

$$\omega = \sqrt{\frac{600\,\text{N/m}}{3\,\text{kg}}} = 14.14\,\text{rad/s}$$

Substitute in equation (1) and evaluate A:

$$A = \frac{2\,\text{m/s}}{14.14\,\text{s}^{-1}} = \boxed{14.1\,\text{cm}}$$

Express and evaluate the period of the oscillator's period:

$$T = \frac{2\pi}{\omega} = \frac{2\pi}{14.14\,\text{s}^{-1}} = \boxed{0.444\,\text{s}}$$

(*b*) For an elastic collision:

$$v_{\text{max}} = v_{2\text{f}} = \frac{2m_1}{m_1 + m_2} v_{1\text{i}}$$

Substitute numerical values and evaluate v_{max}:

$$v_{max} = \frac{2(1\,\text{kg})}{3\,\text{kg}}(6\,\text{m/s}) = 4\,\text{m/s}$$

Using its definition, evaluate the angular frequency of the oscillator:

$$\omega = \sqrt{\frac{k}{m_2}} = \sqrt{\frac{600\,\text{N/m}}{2\,\text{kg}}} = 17.32\,\text{rad/s}$$

Substitute in equation (1) and evaluate A:

$$A = \frac{4\,\text{m/s}}{17.32\,\text{s}^{-1}} = \boxed{23.1\,\text{cm}}$$

Express and evaluate the period of the oscillator's period:

$$T = \frac{2\pi}{\omega} = \frac{2\pi}{17.32\,\text{s}^{-1}} = \boxed{0.363\,\text{s}}$$

(*c*) For the perfectly inelastic collision:

$$x(t) = (14.1\,\text{cm})\cos\left[\left(14.1\,\text{s}^{-1}\right)t + \delta\right] \quad (2)$$

Use the initial conditions to evaluate δ:

$$\delta = \tan^{-1}\left(-\frac{v_0}{\omega x_0}\right) = \tan^{-1}\left(-\frac{v_0}{\omega(0)}\right) = -\frac{\pi}{2}$$

Substitute in equation (2) to obtain:

$$x(t) = (14.1\,\text{cm})\cos\left[\left(14.1\,\text{s}^{-1}\right)t - \frac{\pi}{2}\right] = \boxed{(14.1\,\text{cm})\sin\left[\left(14.1\,\text{s}^{-1}\right)t\right]}$$

For the elastic collision:

$$x(t) = (23.1\,\text{cm})\cos\left[\left(17.3\,\text{s}^{-1}\right)t + \delta\right] \quad (3)$$

Use the initial conditions to evaluate δ:

$$\delta = \tan^{-1}\left(-\frac{v_0}{\omega x_0}\right) = \tan^{-1}\left(-\frac{v_0}{\omega(0)}\right) = -\frac{\pi}{2}$$

Substitute in equation (3) to obtain:

$$x(t) = (23.1\,\text{cm})\cos\left[\left(17.3\,\text{s}^{-1}\right)t - \frac{\pi}{2}\right] = \boxed{(23.1\,\text{cm})\sin\left[\left(17.3\,\text{s}^{-1}\right)t\right]}$$

General Problems

96 •

Picture the Problem The particle's displacement is of the form $x = A\cos(\omega t + \delta)$. Thus, we have $A = 0.4$ m, $\omega = 3$ rad/s, and $\delta = \pi/4$. We can find the frequency of the motion from its angular frequency and the period from the frequency. The particle's position at $t = 0$ and $t = 0.5$ s can be found directly from its displacement function.

(*a*) Express and evaluate the frequency of the particle's motion:

$$f=\frac{\omega}{2\pi}=\frac{3\,\text{rad/s}}{2\pi}=\boxed{0.477\,\text{Hz}}$$

Use the relationship between the frequency and the period of the particle's motion to find its period:

$$T=\frac{1}{f}=\frac{1}{0.477\,\text{s}^{-1}}=\boxed{2.09\,\text{s}}$$

(*b*) Using the expression for the particle's displacement, find its position at $t = 0$:

$$x(0)=(0.4\,\text{m})\cos\left[(3\,\text{rad/s})(0)+\frac{\pi}{4}\right]$$
$$=(0.4\,\text{m})\cos\left[\frac{\pi}{4}\right]=\boxed{0.283\,\text{m}}$$

(*c*) Using the expression for the particle's displacement, find its position at $t = 0.5$ s:

$$x(0)=(0.4\,\text{m})\cos\left[(3\,\text{rad/s})(0.5\,\text{s})+\frac{\pi}{4}\right]$$
$$=(0.4\,\text{m})\cos[2.29\,\text{rad}]$$
$$=\boxed{-0.264\,\text{m}}$$

97 •

Picture the Problem We can express the velocity of the particle by differentiating its displacement with respect to time.

(*a*) Differentiate the particle's displacement to obtain:

$$v=\frac{dx}{dt}$$
$$=\frac{d}{dt}\left\{(0.4\,\text{m})\sin\left[(3\,\text{rad/s})t+\frac{\pi}{4}\right]\right\}$$
$$=\boxed{-(1.2\,\text{m/s})\sin\left[(3\,\text{rad/s})t+\frac{\pi}{4}\right]}$$

(*b*) Evaluate the result in part (*a*) at $t = 0$:

$$v(0)=-(1.2\,\text{m/s})\sin\left[(3\,\text{rad/s})(0)+\frac{\pi}{4}\right]$$
$$=-(1.2\,\text{m/s})\sin\left[\frac{\pi}{4}\right]$$
$$=\boxed{-0.849\,\text{m/s}}$$

(*c*) By inspection of the result in part (*a*) (or from $v_{max}=A\omega$):

$$v_{max}=\boxed{1.20\,\text{m/s}}$$

(*d*) Substitute v_{max} for v to obtain:

$$1.2\,\text{m/s}=-(1.2\,\text{m/s})\sin\left[(3\,\text{rad/s})t'+\frac{\pi}{4}\right]$$

or

$$(3\,\text{rad/s})t' + \frac{\pi}{4} = \sin^{-1}(-1) = \frac{3\pi}{2}$$

Solve for t' to obtain:

$$t' = \boxed{1.31\,\text{s}}$$

98 •

Picture the Problem Let Δy represent the amount by which the spring stretches. We'll apply a condition for equilibrium to the object to relate the amount the spring has stretched to the angular frequency of its motion and then solve this equation for Δy.

Apply $\sum_i F_y = 0$ to the object when it is in its equilibrium position and solve for the elongation of the spring:

$$k\Delta y - mg = 0$$

or

$$\Delta y = \frac{m}{k}g = \frac{g}{\omega^2}$$

Relate the angular frequency of the object's motion to its period:

$$\omega = \frac{2\pi}{T}$$

Substitute to obtain:

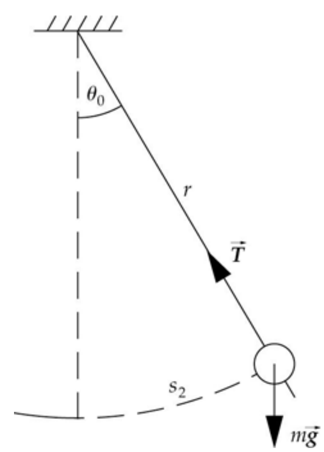
$$\Delta y = \left(\frac{T}{2\pi}\right)^2 g$$

Substitute numerical values and evaluate Δx:

$$\Delta y = \left(\frac{4.5\,\text{s}}{2\pi}\right)^2 (9.81\,\text{m/s}^2) = \boxed{5.03\,\text{m}}$$

***99** ••

Picture the Problem Compare the forces acting on the particle to the right in Figure 14-36 with the forces shown acting on the bob of the simple pendulum shown in the free-body diagram to the right. Because there is no friction, the only forces acting on the particle are *mg* and the normal force acting radially inward. In (*b*), we can think of the particles as the bobs of simple pendulums of equal length.

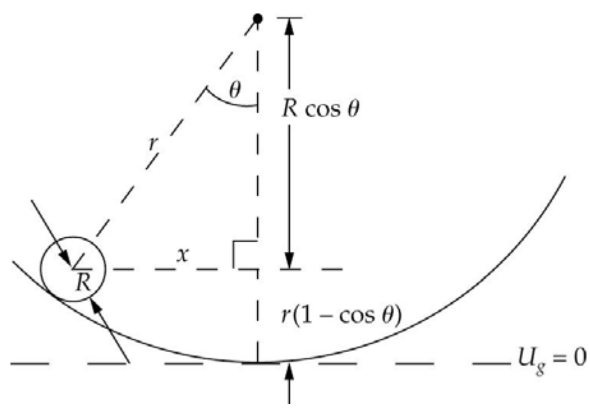


(*a*) The normal force is identical to the tension in a string of length *r* that keeps the particle moving in a circular path and a component of *mg* provides, for small displacements θ_0 or s_2, the linear restoring force required for oscillatory motion.

(*b*) The particles meet at the bottom. Because s_1 and s_2 are both much smaller than *r*, the particles behave like the bobs of simple pendulums of equal length; therefore they have the same periods.

100 ••

Picture the Problem The diagram shows the ball when it is a horizontal distance *x* from the bottom of the bowl. Note that we've chosen the zero of gravitational potential energy to be at the bottom of the bowl. The total energy of the ball is the sum of its potential energy and kinetic energies due to translation and rotation. Once we've obtained an expression for the total energy of the rolling ball, we can require, because the surface is frictionless, that the total energy of the sliding object be the same as that of the rolling ball. Because the motion of the ball is simple harmonic motion, we can assume a solution to its differential equation of motion and express the total energy of the ball in terms of this assumed solution. Doing so will lead us to an expression that we can solve for the oscillation frequency of the ball.



(*a*) Express the total energy *E* of the ball:

$$E = U + K = U + K_{\text{trans}} + K_{\text{rot}} \qquad (1)$$

Referring to the diagram shown above and assuming that $R << r$, express the potential energy of the ball when it is a horizontal distance *x* from the bottom of the bowl:

$$U(x) = mgr(1 - \cos\theta)$$

Express $\cos\theta$ as a power series:

$$\cos\theta = 1 - \frac{\theta^2}{2!} + \frac{\theta^4}{4!} + \ldots$$

For $\theta << 1$:

$$\cos\theta \approx 1 - \frac{\theta^2}{2!}$$

Substitute to obtain:

$$U(x) \approx mgr\left[1 - \left(1 - \frac{\theta^2}{2!}\right)\right] = \tfrac{1}{2} mgr\theta^2$$

For $R << r$:

$$\theta \approx \frac{x}{r}$$

Substitute to obtain:

$$U(x) = \frac{mgx^2}{2r}$$

Substitute in equation (1):

$$E = \frac{mgx^2}{2r} + \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2$$

Because the ball is rolling without slipping, $v = R\omega$. Substitute for ω and I to obtain:

$$E = \frac{mgx^2}{2r} + \frac{1}{2}mv^2 + \frac{1}{2}\left(\frac{2}{5}mR^2\right)\left(\frac{v}{R}\right)^2$$

Simplify to obtain:

$$E = \boxed{\frac{mgx^2}{2r} + \frac{7}{10}mv^2}$$

(*b*) Because energy is conserved if the side of the bowl is frictionless:

$$E = \frac{mgx^2}{2r} + \frac{7}{10}mv^2 = \text{constant}$$

Because the motion is simple harmonic motion, assume a solution of the form:

$$x = x_0 \cos(\omega t + \delta)$$

Differentiate this assumed solution with respect to time to obtain:

$$v = -\omega x_0 \sin(\omega t + \delta)$$

Substitute to obtain:

$$\begin{aligned} E &= \frac{mg}{2r}\left(x_0 \cos(\omega t + \delta)\right)^2 \\ &\quad + \frac{7}{10}m\left(-\omega x_0 \sin(\omega t + \delta)\right)^2 \\ &= \frac{mgx_0^2}{2r}\cos^2(\omega t + \delta) \\ &\quad + \frac{7m\omega^2 x_0^2}{10}\sin^2(\omega t + \delta) \end{aligned}$$

Express the condition the E = constant:

$$\frac{mgx_0^2}{2r} = \frac{7m\omega^2 x_0^2}{10} \text{ or } \frac{g}{r} = \frac{7\omega^2}{5}$$

Solve for ω to obtain:

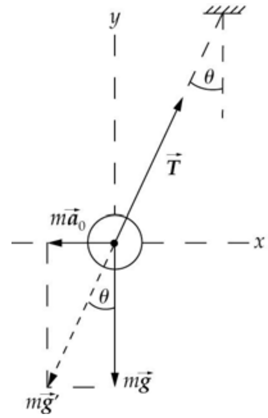
$$\omega = \boxed{\sqrt{\frac{5g}{7r}}}$$

101 ••

Picture the Problem Assume that the plane is accelerating to the right with an acceleration a_0. The free-body diagram shows the forces on the bob as seen in the accelerated frame of the airplane. Let g' represent the effective value of the acceleration due to gravity. The period of the yo-yo is given by

$$T = 2\pi\sqrt{L/g'}$$

where g' is the effective value of the acceleration due to gravity.



Express the period of your yo-yo pendulum as a function of the effective value for the acceleration due to gravity:

$$T = 2\pi\sqrt{\frac{L}{g'}}$$

Using the FBD, relate g' and g:

$$mg = mg'\cos\theta \Rightarrow g' = \frac{g}{\cos\theta}$$

Substitute to obtain:

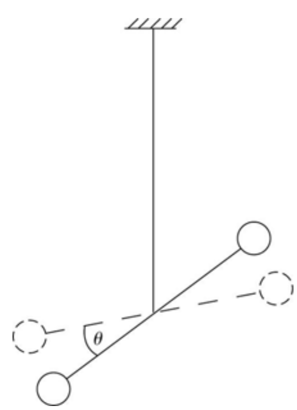
$$T = 2\pi\sqrt{\frac{L\cos\theta}{g}}$$

Substitute numerical values and evaluate T:

$$T = 2\pi\sqrt{\frac{(0.7\,\text{m})\cos 22°}{9.81\,\text{m/s}^2}} = \boxed{1.62\,\text{s}}$$

102 ••

Picture the Problem The diagram shows the wire described in the problem statement with an object of moment of inertia I suspended from its end. We can apply Newton's 2nd law to the suspended object to obtain its differential equation of motion. By comparing this equation to the equation of a simple harmonic oscillator, we can show that $\omega = \sqrt{\kappa/I}$.



Apply $\sum\tau = I\alpha$ to the object hung from the wire to obtain:

$$-\kappa\theta = I\alpha = I\frac{d^2\theta}{dt^2}$$

Divide both sides of this differential equation by I to obtain:

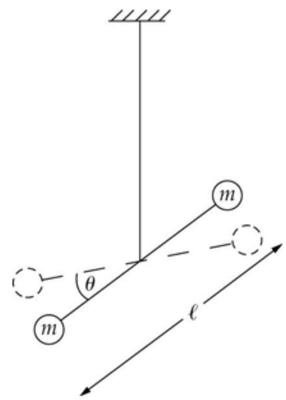
$$\frac{d^2\theta}{dt^2}+\frac{\kappa}{I}\theta=0$$

This equation can be written as:

$$\frac{d^2\theta}{dt^2}+\omega^2\theta=0 \text{ where } \boxed{\omega=\sqrt{\frac{\kappa}{I}}}$$

103 ••

Picture the Problem The diagram shows the torsion balance described in the problem statement. We can apply Newton's 2nd law to the suspended object to obtain its differential equation of motion. By comparing this equation and its solution to that of a simple harmonic oscillator, we can obtain an equation that we can solve for the torsion constant κ.



Apply $\sum\tau=I\alpha$ to the torsion pendulum:

$$-\kappa\theta=I\alpha=I\frac{d^2\theta}{dt^2}$$

or

$$\frac{d^2\theta}{dt^2}+\frac{\kappa}{I}\theta=0 \qquad (1)$$

The differential equation of simple harmonic motion is:

$$\frac{d^2x}{dt^2}+\omega^2x=0$$

where

$$x(t)=x_0\cos(\omega t+\delta) \text{ and } \omega=\frac{2\pi}{T}$$

The solution to equation (1) is:

$$\theta(t)=\theta_0\cos(\omega t+\delta)$$

where

$$\omega=\sqrt{\frac{\kappa}{I}}$$

Solve for κ to obtain:

$$\kappa=\omega^2I$$

Express the moment of inertia of the torsion pendulum:

$$I = 2m\left(\frac{\ell}{2}\right)^2 = \frac{m\ell^2}{2}$$

Substitute to obtain:

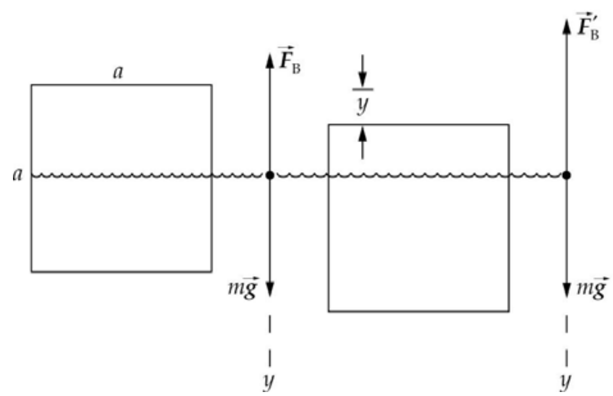
$$\kappa = \frac{\omega^2 m\ell^2}{2} = \frac{4\pi^2 m\ell^2}{2T^2} = \frac{2\pi^2 m\ell^2}{T^2}$$

Substitute numerical values and evaluate κ:

$$\kappa = \frac{2\pi^2(0.050\,\text{kg})(0.05\,\text{m})^2}{(80\,\text{s})^2} = \boxed{3.86\times10^{-7}\,\text{N}\cdot\text{m/rad}}$$

***104 ••**

Picture the Problem Choose a coordinate system in which the direction the cube is initially displaced (downward) is the positive *y* direction. The figure shows the forces acting on the cube when it is in equilibrium floating in the water and when it has been pushed down a small distance *y*. We can find the period of its oscillatory motion from its angular frequency. By applying Newton's 2nd law to the cube, we can obtain its equation of motion; from this equation we can determine the angular frequency of the cube's small-amplitude oscillations.



Express the period of oscillation in terms of the angular frequency of the oscillations:

$$T = \frac{2\pi}{\omega} \qquad (1)$$

Apply $\sum F_y = 0$ to the cube when it is floating in the water:

$$mg - F_B = 0$$

Apply $\sum T_y = ma_y$ to the cube when it is pushed down a small distance *y*:

$$mg - F_B' = ma_y$$

Eliminate *mg* between these equations to obtain:

$$F_B - F_B^{'} = ma_y$$

or

$$\Delta F_B = F_B - F_B^{'} = ma_y$$

For *y* << 1:

$$\Delta F_B \approx dF_B = -\rho Vg = -a^2 \rho gy = m\frac{d^2 y}{dt^2}$$

Rewrite the equation of motion as:

$$m\frac{d^2 y}{dt^2} = -a^2 \rho gy$$

or

$$\frac{d^2 y}{dt^2} = -\frac{a^2 \rho g}{m} y = -\omega^2 y$$

where $\omega^2 = \frac{a^2 \rho g}{m}$

Solve for ω:

$$\omega = a\sqrt{\frac{\rho g}{m}}$$

Substitute in equation (1) to obtain:

$$T = \frac{2\pi}{a\sqrt{\frac{\rho g}{m}}} = \boxed{\frac{2\pi}{a}\sqrt{\frac{m}{\rho g}}}$$

105 ••

Picture the Problem Assume that the density of the earth ρ is constant and let *m* represent the mass of the clock. We can decide the question of where the clock is more accurate by applying the law of gravitation to the clock at a depth *h* below/above the surface of the earth and at the earth's surface and expressing the ratios of the acceleration due to gravity below/above the surface of the earth to its value at the surface of the earth.

Express the gravitational force acting on the clock when it is at a depth *h* in a mine:

$$mg' = \frac{GM'm}{(R_E - h)^2}$$

where *M′* is the mass between the location of the clock and the center of the earth.

Express the gravitational force acting on the clock at the surface of the earth:

$$mg = \frac{GM_E m}{R_E^2}$$

Divide the first of these equations by the second to obtain:

$$\frac{g'}{g}=\frac{\dfrac{GM'}{(R_E-h)^2}}{\dfrac{GM_E}{R_E^2}}=\frac{M'}{M_E}\frac{R_E^2}{(R_E-h)^2}$$

Express M':

$$M'=\rho V'=\tfrac{4}{3}\pi\rho(R_E-h)^3$$

Express M_E:

$$M_E=\rho V=\tfrac{4}{3}\pi\rho R_E^3$$

Substitute to obtain:

$$\frac{g'}{g}=\frac{\frac{4}{3}\pi\rho(R_E-h)^3}{\frac{4}{3}\pi\rho R_E^3}\frac{R_E^2}{(R_E-h)^2}$$

Simplify and solve for g':

$$g'=g\left(\frac{R_E-h}{R_E}\right)=g\left(1-\frac{h}{R_E}\right)$$

or

$$g'=g\left(1-\frac{h}{R_E}\right) \qquad (1)$$

Express the gravitational force acting on the clock when it is at an elevation h:

$$mg''=\frac{GM_Em}{(R_E+h)^2}$$

Express the gravitational force acting on the clock at the surface of the earth:

$$mg=\frac{GM_Em}{R_E^2}$$

Divide the first of these equations by the second to obtain:

$$\frac{g''}{g}=\frac{\dfrac{GM_E}{(R_E+h)^2}}{\dfrac{GM_E}{R_E^2}}=\frac{R_E^2}{(R_E-h)^2}$$

$$=\frac{1}{\left(1+\dfrac{h}{R_E}\right)^2}$$

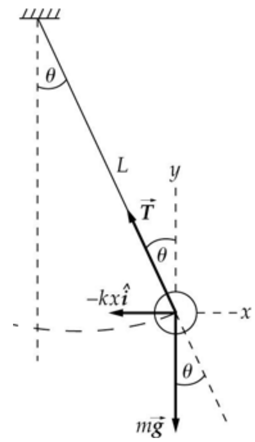
Solve for g'':

$$g''=g\left(1+\frac{h}{R_E}\right)^{-2}$$

Comparing equations (1) and (2), we see that g' is closer to g than is g''. Thus, the error is greater if the clock is elevated.

106 ••

Picture the Problem The figure shows this system when it has an angular displacement θ. The period of the system is related to its angular frequency according to $T = 2\pi/\omega$. We can find the equation of motion of the system by applying Newton's 2nd law. By writing this equation in terms of θ and using a small-angle approximation, we'll find an expression for ω that we can use to express T.



(*a*) Express the period of the system in terms of its angular frequency:

$$T = \frac{2\pi}{\omega} \qquad (1)$$

Apply $\sum \vec{F} = m\vec{a}$ to the bob:

$$\sum F_x = -kx - T\sin\theta = Ma_x$$

and

$$\sum F_y = T\cos\theta - Mg = 0$$

Eliminate T between the two equations to obtain:

$$-kx - Mg\tan\theta = Ma_x$$

Noting that $x = L\theta$ and $a_x = L\alpha = L\frac{d^2\theta}{dt^2}$, eliminate the variable x in favor of θ:

$$ML\frac{d^2\theta}{dt^2} = -kL\theta - Mg\tan\theta$$

For $\theta << 1$, $\tan\theta \approx \theta$:

$$ML\frac{d^2\theta}{dt^2} = -kL\theta - Mg\theta = -(kL + Mg)\theta$$

or

$$\frac{d^2\theta}{dt^2} = -\left(\frac{k}{M} + \frac{g}{L}\right)\theta = -\omega^2\theta$$

where

$$\omega = \sqrt{\frac{k}{M} + \frac{g}{L}}$$

Substitute in equation (1) to obtain:

$$T = \boxed{\dfrac{2\pi}{\sqrt{\dfrac{k}{M} + \dfrac{g}{L}}}}$$

(*b*) When $T = 2$ s and $M = 1$ kg we have:

$$2 = \frac{2\pi}{\sqrt{\dfrac{g}{L}}}$$

When $T = 1$ s we have:

$$1 = \frac{2\pi}{\sqrt{k + \dfrac{g}{L}}}$$

Solve these equations simultaneously to obtain:

$$k = \boxed{29.6\,\text{N/m}}$$

107 ••

Picture the Problem Applying Newton's 2nd law to the first object as it is about to slip will allow us to express μ_s in terms of the maximum acceleration of the system which, in turn, depends on the amplitude and angular frequency of the oscillatory motion.

(*a*) Apply $\sum F_x = ma_x$ to the second object as it is about to slip:

$$f_{s,\max} = m_2 a_{\max}$$

Apply $\sum F_y = 0$ to the second object:

$$F_n - m_2 g = 0$$

Use $f_{s,\max} = \mu_s F_n$ to eliminate $f_{s,\max}$ and F_n between the two equations:

$$\mu_s m_2 g = m_2 a_{\max}$$

and

$$\mu_s = \frac{a_{\max}}{g}$$

Relate the maximum acceleration of the oscillator to its amplitude and angular frequency:

$$a_{\max} = A\omega^2 = A\frac{k}{m_1 + m_2}$$

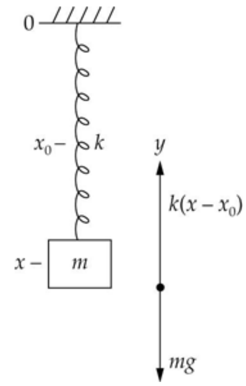
Substitute for $a_{\max}$ to obtain:

$$\mu_s = \boxed{\frac{Ak}{(m_1 + m_2)g}}$$

(*b*) A is unchanged. E is unchanged because $E=\frac{1}{2}kA^2$. ω is reduced by increasing the total mass of the system and T is increased.

108 ••

Picture the Problem The diagram shows the box hanging from the stretched spring and the free-body diagram when the box is in equilibrium. We can apply $\sum F_y = 0$ to the box to derive an expression for *x*. In (*b*) and (*c*), we can proceed similarly to obtain expressions for the effective spring constant, the new equilibrium position of the box, and frequency of oscillations when the box is released.



(*a*) Apply $\sum F_y = 0$ to the box to obtain:

$$k(x-x_0)-mg=0$$

Solve for *x*:

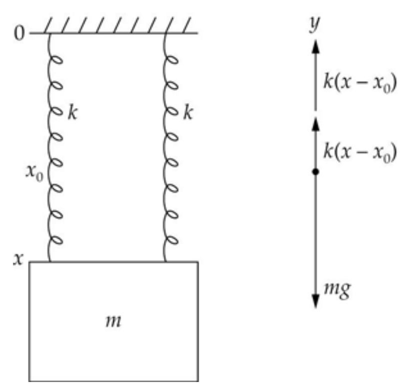
$$x=\frac{mg}{k}+x_0$$

Substitute numerical values and evaluate *x*:

$$x=\frac{(100\,\text{kg})(9.81\,\text{m/s}^2)}{500\,\text{N/m}}+0.5\text{m}$$

$$=\boxed{2.46\,\text{m}}$$

(*b*) Draw the free-body diagram for the block with the two springs exerting equal upward forces on it:



Apply $\sum F_y = 0$ to the box to obtain:

$$k(x-x_0)+k(x-x_0)-mg=0$$

or

$$k_{\text{eff}}(x-x_0)-mg=0 \qquad (1)$$

where

$$k_{\text{eff}}=2k$$

When the box is displaced from this equilibrium position and released, its motion is simple harmonic motion and its frequency is given by:

$$\omega = \sqrt{\frac{k_{\text{eff}}}{m}} = \sqrt{\frac{2k}{m}}$$

Substitute numerical values and evaluate ω:

$$\omega = \sqrt{\frac{2(500\,\text{N/m})}{100\,\text{kg}}} = \boxed{3.16\,\text{rad/s}}$$

(c) Solve equation (1) for x:

$$x = \frac{mg}{2k} + x_0$$

Substitute numerical values and evaluate x:

$$x = \frac{(100\,\text{kg})(9.81\,\text{m/s}^2)}{2(500\,\text{N/m})} + 0.5\,\text{m} = \boxed{1.48\,\text{m}}$$

109 ••

Picture the Problem We'll differentiate the expression for the period of simple pendulum $T = 2\pi\sqrt{\frac{L}{g}}$ with respect to g, separate the variables, and use a differential approximation to establish that $\frac{\Delta T}{T} \approx -\frac{1}{2}\frac{\Delta g}{g}$.

(a) Express the period of a simple pendulum in terms of its length and the local value of the acceleration due to gravity:

$$T = 2\pi\sqrt{\frac{L}{g}}$$

Differentiate this expression with respect to g to obtain:

$$\frac{dT}{dg} = \frac{d}{dg}\left[2\pi\sqrt{L}g^{-1/2}\right] = -\pi\sqrt{L}g^{-3/2} = -\frac{T}{2g}$$

Separate the variables to obtain:

$$\frac{dT}{T} = -\frac{1}{2}\frac{dg}{g}$$

Approximate dT and dg by ΔT and Δg for $\Delta g << g$:

$$\frac{\Delta T}{T} \approx \boxed{-\frac{1}{2}\frac{\Delta g}{g}}$$

(b) Solve the result in part (a) for Δg:

$$\Delta g = -2g\frac{\Delta T}{T}$$

Express $\Delta T/T$:

$$\frac{\Delta T}{T}=-90\frac{\text{s}}{\text{d}}\times\frac{1\,\text{d}}{24\,\text{h}}\times\frac{1\,\text{h}}{3600\,\text{s}}=-1.04\times10^{-3}$$

Substitute and evaluate Δg:

$$\Delta g=-2\left(9.81\,\text{m/s}^2\right)\left(-1.04\times10^{-3}\right)=0.0204\,\text{m/s}^2=\boxed{2.04\,\text{cm/s}^2}$$

110 ••

Picture the Problem We can find the frequency of the vibrating system from its angular frequency; this depends on the spring constant and the total mass involved in the motion. The energy of the system can be found from the amplitude of its motion.

(*a*) Relate the frequency of the vibrating system to its angular frequency:

$$f=\frac{\omega}{2\pi}=\frac{1}{2\pi}\sqrt{\frac{k}{2m}}$$

Substitute numerical values and evaluate *f*:

$$f=\frac{1}{2\pi}\sqrt{\frac{240\,\text{N/m}}{2(0.6\,\text{kg})}}=\boxed{2.25\,\text{Hz}}$$

Express the total energy of the system:

$$E=\tfrac{1}{2}kA^2$$

Substitute numerical values and evaluate *E*:

$$E=\tfrac{1}{2}(240\,\text{N/m})(0.6\,\text{m})^2=\boxed{43.2\,\text{J}}$$

(*b*) (1) The glue dissolves when the spring is at maximum compression:

Relate the frequency to the system's new angular frequency:

$$f_1=\frac{\omega_1}{2\pi}=\frac{1}{2\pi}\sqrt{\frac{k}{m}}$$

Substitute numerical values and evaluate f_1:

$$f_1=\frac{1}{2\pi}\sqrt{\frac{240\,\text{N/m}}{0.6\,\text{kg}}}=\boxed{3.18\,\text{Hz}}$$

Express the system's new amplitude as a function of the oscillator's maximum speed and its new angular frequency:

$$A_1=\frac{v_{\text{max}}}{\omega_1}=v_{\text{max}}\sqrt{\frac{m}{k}}$$

Find the maximum speed of the oscillator:

$$v_{\text{max}}=A\omega=2\pi fA=2\pi\left(2.25\,\text{s}^{-1}\right)(0.6\,\text{m})=8.48\,\text{m/s}$$

Substitute and evaluate A_1:

$$A_1 = (8.48\,\text{m/s})\sqrt{\frac{0.6\,\text{kg}}{240\,\text{N/m}}} = \boxed{42.4\,\text{cm}}$$

Express and evaluate the energy of the system:

$$E_1 = \tfrac{1}{2}kA_1^2 = \tfrac{1}{2}(240\,\text{N/m})(0.424\,\text{m})^2 = \boxed{21.6\,\text{J}}$$

(*b*) (2) The glue dissolves when the spring is at maximum extension and f_2 is the same as f_1:

$$f_2 = \boxed{3.18\,\text{Hz}}$$

Because the second object is at rest, the amplitude and energy of the system are unchanged:

$$A_2 = A = \boxed{0.600\,\text{m}}$$

and

$$E_2 = E = \boxed{43.2\,\text{J}}$$

111 ••

Picture the Problem Choose a coordinate system in which the positive *x* direction is to the right and assume that the object is displaced to the right. In case (*a*), note that the two springs undergo the same displacement whereas in (*b*) they experience the same force.

(*a*) Express the net force acting on the object:

$$F_{\text{net}} = -k_1x - k_2x = -(k_1 + k_2)x = -k_{\text{eff}}x$$

where $k_{\text{eff}} = \boxed{k_1 + k_2}$

(*b*) Express the force acting on each spring and solve for x_2:

$$F = -k_1x_1 = -k_2x_2$$

or

$$x_2 = \frac{k_1}{k_2}x_1$$

Express the total extension of the springs:

$$x_1 + x_2 = -\frac{F}{k_{\text{eff}}}$$

Solve for k_{eff}:

$$k_{\text{eff}} = -\frac{F}{x_1 + x_2} = -\frac{-k_1x_1}{x_1 + x_2} = \frac{k_1x_1}{x_1 + \frac{k_1}{k_2}x_1} = \frac{1}{\frac{1}{k_1} + \frac{1}{k_2}}$$

Take the reciprocal of both sides of the equation to obtain:

$$\frac{1}{k_{\text{eff}}} = \boxed{\frac{1}{k_1} + \frac{1}{k_2}}$$

***112 ••**

Picture the Problem If the displacement of the block is $y = A \sin \omega t$, its acceleration is $a = -\omega^2 A\sin\omega t$.

(*a*) At maximum upward extension, the block is momentarily at rest. Its downward acceleration is g. The downward acceleration of the piston is $\omega^2 A$. Therefore, if $\omega^2 A > g$, the block will separate from the piston.

(*b*) Express the acceleration of the small block:

$$a = -A\omega^2 \sin \omega t$$

For $\omega^2 A = 3g$ and $A = 15$ cm:

$$a = -3g \sin \omega t = -g$$

Solve for t:

$$t = \frac{1}{\omega}\sin^{-1}\left(\frac{1}{3}\right) = \sqrt{\frac{A}{3g}}\sin^{-1}\left(\frac{1}{3}\right)$$

Substitute numerical values and evaluate t:

$$t = \sqrt{\frac{0.15\,\text{m}}{3(9.81\,\text{m/s}^2)}}\sin^{-1}\frac{1}{3} = \boxed{0.0243\,\text{s}}$$

113 ••

Picture the Problem The plunger and ball are moving with their maximum speed as they pass through their equilibrium position ($x = 0$). Once it has passed its equilibrium position, the acceleration of the plunger becomes negative; therefore it begins to slow down and the ball, continuing with speed v_s, separates from the plunger. We can find this separation speed by equating it to the maximum speed of the plunger. Application of conservation of energy to the motion of the plunger will allow us to express the distance at which the plunger comes momentarily to rest.

(*a*) The ball will leave the plunger when the plunger is moving with its maximum speed; i.e., at its equilibrium position:

$$x = \boxed{0}$$

(*b*) Express the speed of the ball upon separation in terms of the maximum speed of the plunger:

$$v_s = v_{\max} = A\omega = x_0\omega$$

The angular frequency is given by:

$$\omega = \sqrt{\frac{k}{m_b + m_p}}$$

Substitute to obtain:

$$v_s = \boxed{x_0\sqrt{\frac{k}{m_b + m_p}}}$$

(*c*) Apply conservation of energy to the plunger:

$$K_f - K_i + U_{f,s} - U_{i,s} = 0$$

or, because $K_f = U_i = 0$,

$$-\tfrac{1}{2}m_p v_s^2 + \tfrac{1}{2}kx_f^2 = 0$$

Solve for x_f:

$$x_f = \sqrt{\frac{m_p}{k}}v_s$$

Substitute for v_s and simplify to obtain:

$$x_f = \boxed{x_0\sqrt{\frac{m_p}{m_b + m_p}}}$$

114 ••

Picture the Problem Applying Newton's 2nd law to the box as it is about to slip will allow us to express μ_s in terms of the maximum acceleration of the platform which, in turn, depends on the amplitude and angular frequency of the oscillatory motion.

(*a*) Apply $\sum F_x = ma_x$ to the box as it is about to slip:

$$f_{s,max} = ma_{max}$$

Apply $\sum F_y = 0$ to the box:

$$F_n - mg = 0$$

Use $f_{s,max} = \mu_s F_n$ to eliminate $f_{s,max}$ and F_n between the two equations:

$$\mu_s mg = ma_{max}$$

and

$$\mu_s = \frac{a_{max}}{g}$$

Relate the maximum acceleration of the oscillator to its amplitude and angular frequency:

$$a_{max} = A\omega^2$$

Substitute for a_{max} :

$$\mu_s = \frac{A\omega^2}{g} = \frac{4\pi^2 A}{T^2 g}$$

Substitute numerical values and evaluate μ_s:

$$\mu_s = \frac{4\pi^2(0.4\,\text{m})}{(0.8\,\text{s})^2(9.81\,\text{m/s}^2)} = \boxed{2.52}$$

(*b*) Solve the equation derived above for A_{max}:

$$A_{max} = \frac{\mu_s g}{\omega^2} = \frac{\mu_s g T^2}{4\pi^2}$$

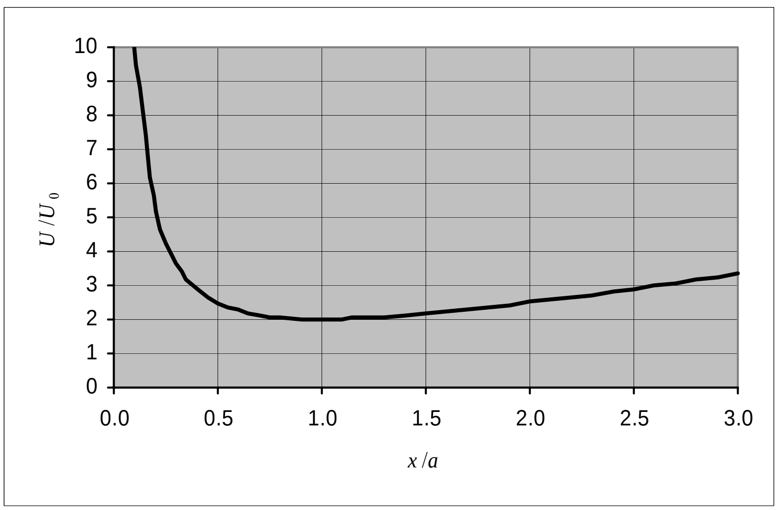
Substitute numerical values and evaluate A_{max}:

$$A_{max} = \frac{(0.4)(9.81\,\text{m/s}^2)(0.8\,\text{s})^2}{4\pi^2} = \boxed{6.36\,\text{cm}}$$

115 •••

Picture the Problem In (*b*), we can use the condition $F_{net} = dU/dx = 0$ for stable equilibrium to find the value of $x = x_0$ at stable equilibrium. In (*c*) and (*d*), we can simply follow the outline provided in the problem statement. In (*e*), we can obtain the frequency from $f = \frac{1}{2\pi}\sqrt{\frac{k}{m}}$ using the value for *k* from the potential function.

(*a*) A graph of $U(x)$ follows:



(*b*) Express the condition for equilibrium:

$$F = \frac{dU}{dx} = 0$$

Differentiate U with respect to x:

$$\frac{dU}{dx} = \frac{d}{dx}\left[U_0\left(\frac{x}{a} + \frac{a}{x}\right)\right] = U_0\left[\frac{1}{a} - \frac{a}{x^2}\right] = \frac{U_0}{a}\left(1 - \frac{a^2}{x^2}\right)$$

Set this derivative equal to zero and solve for *x*:

$$\frac{U_0}{a}\left(1-\frac{a^2}{x_0^2}\right)=0$$

and

$$x_0 = \boxed{a} \text{ or } \alpha = \boxed{1}$$

(*c*) Express $U(x_0 + \varepsilon)$:

$$U(x_0+\varepsilon)=U_0\left[\frac{x_0+\varepsilon}{a}+\frac{a}{x_0+\varepsilon}\right]$$

$$=U_0\left[\frac{x_0}{a}+\frac{\varepsilon}{a}+\frac{1}{\frac{x_0}{a}+\frac{\varepsilon}{a}}\right]$$

or, because $x_0 = a$,

$$U(x_0+\varepsilon)=U_0\left[1+\frac{\varepsilon}{a}+\frac{1}{1+\frac{\varepsilon}{a}}\right]$$

$$=\boxed{U_0\left[1+\beta+(1+\beta)^{-1}\right]}$$

where $\beta=\frac{\varepsilon}{a}$

(*d*) Expand $(1+\beta)^{-1}$ to obtain:

$$(1+\beta)^{-1}=1+(-1)\beta+\frac{(-1)(-2)}{2\times 1}\beta^2+...$$

$$\approx 1-\beta+\beta^2$$

Substitute in $U(x_0 + \varepsilon)$:

$$U(x_0+\varepsilon)=U_0\left[1+\beta+1-\beta+\beta^2\right]$$

$$=U_0\left[2+\beta^2\right]$$

$$=2U_0+U_0\frac{\varepsilon^2}{a^2}$$

$$=\boxed{\text{constant}+U_0\frac{\varepsilon^2}{a^2}}$$

(*e*) Express the potential energy of a simple harmonic oscillator:

$$U=\text{constant}+\tfrac{1}{2}k\varepsilon^2$$

If the particle whose potential energy is given in part (*d*) is to undergo simple harmonic motion:

$$k=\frac{2U_0}{a^2}$$

Express the frequency of the simple harmonic motion, substitute for *k*, and simplify to obtain:

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{m}} = \frac{1}{2\pi}\sqrt{\frac{2U_0}{a^2 m}}$$
$$= \boxed{\frac{1}{2\pi a}\sqrt{\frac{2U_0}{m}}}$$

116 •••

Picture the Problem Let *m* represent the mass of the cylindrical drum, *R* its radius, and *k* the stiffness constant of the spring. We can find the angular frequency of the oscillations by equating the maximum kinetic energy of the drum and the maximum energy stored in the spring. We can then express the frequency of the system in terms of its angular frequency. The application of Newton's 2nd law, under on-the-verge-of-sliding conditions, together with the introduction of the oscillator's total energy, will lead us to an expression for the minimum value of the coefficient of static friction.

(*a*) Express the frequency of oscillation of the system for small displacements from equilibrium:

$$f = \frac{\omega}{2\pi} \qquad (1)$$

Express the kinetic energy of the drum and simplify to obtain:

$$K = \tfrac{1}{2}I\omega^2 + \tfrac{1}{2}mv^2$$
$$= \tfrac{1}{2}\left(\tfrac{1}{2}mR^2\right)\left(\frac{v}{R}\right)^2 + \tfrac{1}{2}mv^2$$
$$= \tfrac{3}{4}mv^2$$

Apply conservation of energy to obtain:

$$K_{max} = \tfrac{3}{4}mv_{max}^2 = \tfrac{1}{2}kA^2$$

Substitute $A\omega$ for v_{max}:

$$\tfrac{3}{4}m(A\omega)^2 = \tfrac{1}{2}kA^2$$

Solve for ω:

$$\omega = \sqrt{\frac{2k}{3m}}$$

Substitute in equation (1) to obtain:

$$f = \frac{1}{2\pi}\sqrt{\frac{2k}{3m}}$$

Substitute numerical values and evaluate *f*:

$$f = \frac{1}{2\pi}\sqrt{\frac{2(4000\,\text{N/m})}{3(6\,\text{kg})}} = \boxed{3.36\,\text{Hz}}$$

(*b*) Apply $\sum F_x = 0$ to the drum to

$$kA - f_{s,max} = 0$$

or

establish the condition that governs slipping:

$$kA - \mu_s F_n = 0$$

Using $F_n = mg$, solve for μ_s:

$$\mu_s = \frac{kA}{mg} \qquad (2)$$

Express the oscillator's total energy in terms of the amplitude of its motion:

$$E = \tfrac{1}{2}kA^2 \Rightarrow kA = \sqrt{2Ek}$$

Substitute in equation (2) to obtain:

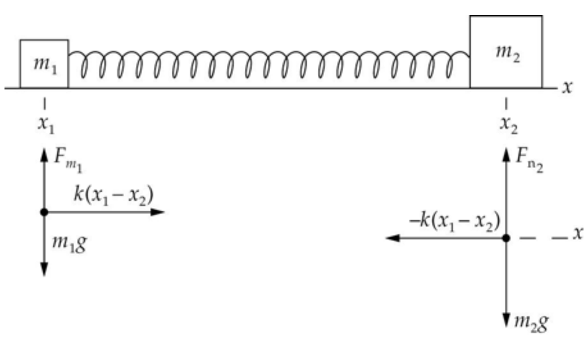
$$\mu_s = \frac{\sqrt{2Ek}}{mg}$$

Substitute numerical values and evaluate μ_s:

$$\mu_s = \frac{\sqrt{2(5\,\text{J})(4000\,\text{N/m})}}{(6\,\text{kg})(9.81\,\text{m/s}^2)} = \boxed{3.40}$$

***117** •••

Picture the Problem The pictorial representation shows the two blocks connected by the spring and displaced from their equilibrium positions. We can apply Newton's 2nd law to each of these coupled oscillators and solve the resulting equations simultaneously to obtain the differential equation of motion of the coupled oscillators. We can then compare this differential equation and its solution to the differential equation of motion of the simple harmonic oscillator and its solution to show that the oscillation frequency is $\omega = (k/\mu)^{1/2}$ where $\mu = m_1m_2/(m_1 + m_2)$ is the reduced mass of the system.



Apply $\sum \vec{F} = m\vec{a}$ to the block whose mass is m_1 and solve for its acceleration:

$$k(x_1 - x_2) = m_1a_1 = m_1\frac{d^2x_1}{dt^2}$$

or

$$a_1 = \frac{d^2x_1}{dt^2} = \frac{k}{m_1}(x_1 - x_2)$$

Apply $\sum \vec{F} = m\vec{a}$ to the block whose mass is m_2 and solve for its

$$-k(x_1 - x_2) = m_2a_2 = m_1\frac{d^2x_2}{dt^2}$$

acceleration: or

$$a_2 = \frac{d^2x_2}{dt^2} = \frac{k}{m_2}(x_2 - x_1)$$

Subtract the first equation from the second to obtain:

$$\frac{d^2(x_2 - x_1)}{dt^2} = \frac{d^2x}{dt^2} = -k\left(\frac{1}{m_1} + \frac{1}{m_2}\right)x$$

where $x = x_2 - x_1$

The reduced mass of the system is:

$$\frac{1}{\mu} = \frac{1}{m_1} + \frac{1}{m_2} \text{ or } \mu = \frac{m_1 m_2}{m_1 + m_2}$$

Substitute to obtain:

$$\frac{d^2x}{dt^2} = -\frac{k}{\mu}x \qquad (1)$$

Compare this differential equation with the differential equation of the simple harmonic oscillator:

$$\frac{d^2x}{dt^2} = -\frac{k}{m}x$$

The solution to this equation is:

$$x = x_0 \cos(\omega t + \delta)$$

where $\omega = \sqrt{\frac{k}{m}}$

Express the solution to equation (1):

$$x = x_0 \cos(\omega t + \delta)$$

where $\omega = \boxed{\sqrt{\frac{k}{\mu}}}$

118 ••

Picture the Problem We can use $\omega = (k/\mu)^{1/2}$ and $\mu = m_1m_2/(m_1 + m_2)$ from Problem 117 to find the spring constant for the HCl molecule.

Use the result of Problem 118 to relate the oscillation frequency to the spring constant and reduced mass of the HCl molecule:

$$\omega = \sqrt{\frac{k}{\mu}}$$

Solve for k to obtain:

$$k = \mu\omega^2$$

Express the reduced mass of the HCl molecule:

$$\mu = \frac{m_1 m_2}{m_1 + m_2}$$

Substitute to obtain:

$$k = \frac{m_1 m_2 \omega^2}{m_1 + m_2}$$

Express the masses of the hydrogen and Cl atoms:

$m_1 = 1\text{ amu} = 1.67\times10^{-27}$ kg
and
$m_2 = 35.45\text{ amu} = 5.92\times10^{-26}$ kg

Substitute numerical values and evaluate k:

$$k = \frac{(1.67\times10^{-27}\text{ kg})(5.92\times10^{-26}\text{ kg})(8.969\times10^{13}\text{ s}^{-1})^2}{1.67\times10^{-27}\text{ kg} + 5.92\times10^{-26}\text{ kg}} = \boxed{13.1\text{ N/m}}$$

119 ••

Picture the Problem In Problem 117, we derived an expression for the oscillation frequency of a spring-and-two-block system as a function of the stiffness constant of the spring and the reduced mass of the two blocks. We can solve this problem, assuming that the "spring constant" does not change, by using the result of Problem 117 and the reduced mass of a deuterium atom and a Cl atom in the equation for the oscillation frequency.

Use the result of Problem 117 to relate the oscillation frequency to the spring constant and reduced mass of the HCl molecule:

$$\omega = \sqrt{\frac{k}{\mu}}$$

Express the reduced mass of the HCl molecule:

$$\mu = \frac{m_1 m_2}{m_1 + m_2}$$

Express the masses of the deuterium and Cl atoms:

$m_1 = 2\text{ amu} = 3.34\times10^{-27}$ kg
and
$m_2 = 35.45\text{ amu} = 5.92\times10^{-26}$ kg

Evaluate the reduced mass of the molecule:

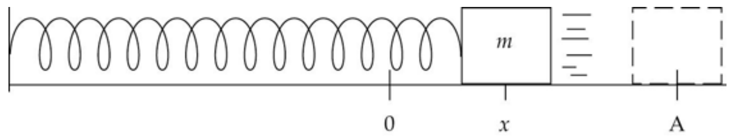
$$\mu = \frac{(3.34\times10^{-27}\text{ kg})(5.92\times10^{-26}\text{ kg})}{3.34\times10^{-27}\text{ kg} + 5.92\times10^{-26}\text{ kg}} = 3.16\times10^{-27}\text{ kg}$$

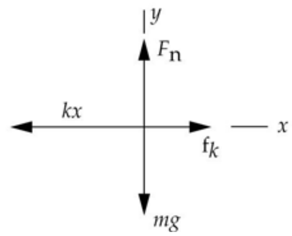
Substitute numerical values and evaluate ω:

$$\omega = \sqrt{\frac{13.1\text{ N/m}}{3.16\times10^{-27}\text{ kg}}} = \boxed{6.44\times10^{13}\text{ rad/s}}$$

120 •••

Picture the Problem The pictorial representation shows the block moving from right to left with an instantaneous displacement x from its equilibrium position. The free-body diagram shows the forces acting on the block during the half-cycles that it moves from right to left. When the block is moving from left to right, the directions of the kinetic friction force and the restoring force exerted by the spring are reversed. We can apply Newton's 2nd law to these motions to obtain the differential equations given in the problem statements and then use their solutions to plot the graph called for in (*c*).





(*a*) Apply $\sum F_x = ma_x$ to the block while it is moving to the left to obtain:

$$f_k - kx = m\frac{d^2x}{dt^2}$$

Using $f_k = \mu_k F_n = \mu_k mg$, eliminate f_k in the differential equation of motion:

$$m\frac{d^2x}{dt^2} = -kx + \mu_k mg$$

or

$$m\frac{d^2x}{dt^2} = -k\left(x - \frac{\mu_k mg}{k}\right)$$

Let $x_0 = \dfrac{\mu_k mg}{k}$ to obtain:

$$m\frac{d^2x}{dt^2} = -k(x - x_0)$$

or

$$\boxed{\frac{d^2x'}{dt^2} = -\frac{k}{m}x' = -\omega^2 x'}$$

provided $x' = x - x_0$ and

$$x_0 = \boxed{\frac{\mu_k mg}{k} = \frac{\mu_k g}{\omega^2}}$$

The solution to the differential equation is:

$$x' = x_0' \cos(\omega t + \delta)$$

and its derivative is

$$v' = -\omega x_0' \sin(\omega t + \delta)$$

The initial conditions are:

$$x'(0) = x - x_0 \text{ and } v'(0) = 0$$

Apply these conditions to obtain:

$$x'(0) = x_0' \cos\delta = x - x_0$$

and

$$v'(0) = -\omega x_0' \sin\delta = 0$$

Solve these equations simultaneously to obtain:

$$\delta = 0 \text{ and } x_0' = x - x_0$$

and

$$x' = (x - x_0)\cos\omega t$$

or

$$\boxed{x = (x - x_0)\cos\omega t + x_0} \qquad (1)$$

(*b*) Apply $\sum \vec{F} = m\vec{a}$ to the block while it is moving to the right to obtain:

$$-f_k - kx = m\frac{d^2x}{dt^2}$$

Using $f_k = \mu_k F_n = \mu_k mg$, eliminate f_k in the differential equation of motion:

$$m\frac{d^2x}{dt^2} = -kx - \mu_k mg$$

or

$$m\frac{d^2x}{dt^2} = -k\left(x + \frac{\mu_k mg}{k}\right)$$

Let $x_0 = \dfrac{\mu_k mg}{k}$ to obtain:

$$m\frac{d^2x}{dt^2} = -k(x + x_0)$$

or

$$\boxed{\frac{d^2x''}{dt^2} = -\frac{k}{m}x'' = -\omega^2 x''}$$

provided $x'' = x + x_0$ and

$$x_0 = \boxed{\frac{\mu_k mg}{k} = \frac{\mu_k g}{\omega^2}}\,.$$

The solution to the differential equation is:

$$x'' = x_0''\cos(\omega t + \delta)$$

and its derivative is

$$v'' = -\omega x_0''\sin(\omega t + \delta)$$

The initial conditions are:

$$x''(0) = x + x_0 \text{ and } v''(0) = 0$$

Apply these conditions to obtain:

$$x''(0) = x_0''\cos\delta = x + x_0$$

and

$$v''(0) = -\omega x_0''\sin\delta = 0$$

Solve these equations simultaneously to obtain:

$$\delta = 0 \text{ and } x_0'' = x + x_0$$

and

$$x'' = (x + x_0)\cos\omega t$$

or

$$\boxed{x = (x + x_0)\cos\omega t - x_0} \qquad (2)$$

(*c*) A spreadsheet program to calculate the position of the oscillator as a function of time (equations (1) and (2)) is shown below. The constants used in the position functions (x_0 = 1 m and T = 2 s were used for simplicity) and the formulas used to calculate the positions are shown in the table. *After each half-period, one must compute a new amplitude for the oscillation, using the final value of the position from the last half-period.*

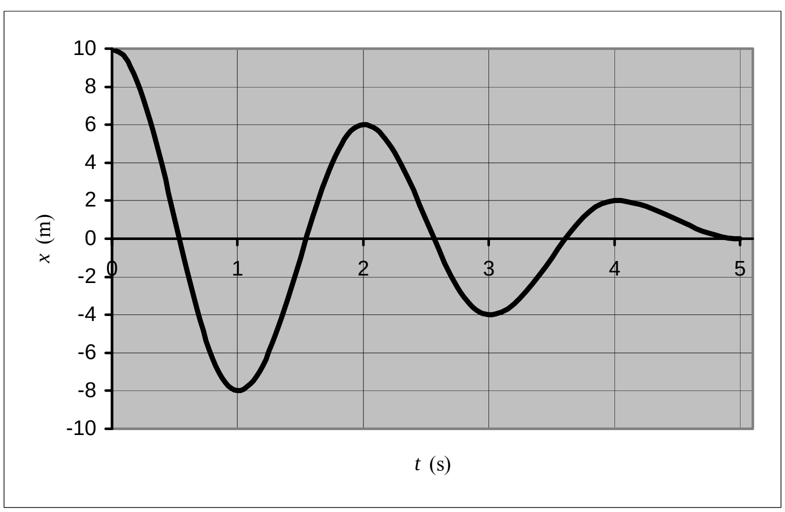
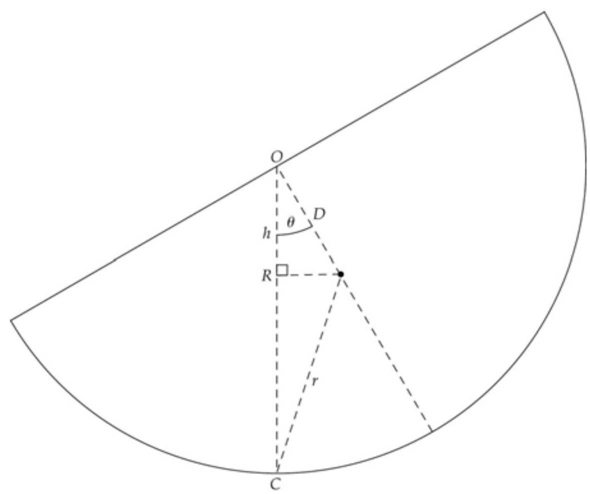
The graph shown below was plotted using the data from columns C (t) and D (x). Note that the motion of the block ceases after five half - cycles.



121 •••

Picture the Problem The diagram shows the half-cylinder displaced from its equilibrium position through an angle θ. The frequency of its motion will be found by expressing the mechanical energy E in terms of θ and $d\theta/dt$. For small θ we will obtain an equation of the form $E = \frac{1}{2}\kappa\theta^2 + \frac{1}{2}I\left(\frac{d\theta}{dt}\right)^2$. Differentiating both sides of this equation with respect to time will lead to $0 = \left(\kappa\theta + I\frac{d^2\theta}{dt^2}\right)\frac{d\theta}{dt}$, an equation that must be valid at all times. Because the situation of interest to us requires that $d\theta/dt$ is not always equal to zero, we have $0 = \kappa\theta + I\frac{d^2\theta}{dt^2}$ or $\frac{d^2\theta}{dt^2} + \frac{\kappa}{I}\theta = 0$, the differential equation of simple harmonic motion with $\omega^2 = \kappa/I$. The distance from O to the center of mass D, where, from Problem 8-39, $D = (4/3\pi)R$, and the distance from the contact point C to the center of mass is r. Finally, we'll take the potential energy to be zero where θ is zero and assume that there is no slipping.



Apply conservation of energy to obtain:

$$E = U + K$$

$$= Mg(h - D) + \frac{1}{2}I_C\left(\frac{d\theta}{dt}\right)^2 \quad (1)$$

From Table 9-1, the moment of inertia of a solid cylinder about an axis perpendicular to its face and through its center is given by:

$$I_{0,\,\text{solid cylinder}} = \frac{1}{2}(2M)R^2 = MR^2$$

where M is the mass of the half-cylinder.

Express the moment of inertia of the half-cylinder about the same axis:

$$I_{0,\text{ half cylinder}} = I_0 = \frac{1}{2}\left[MR^2\right] = \frac{1}{2}MR^2$$

Use the parallel-axis theorem to relate I_{cm} to I_0:

$$I_0 = I_{cm} + MD^2$$

Substitute for I_{cm} and solve for I_{cm}:

$$I_{cm} = I_0 - D^2M = \frac{1}{2}MR^2 - D^2M$$

Apply the parallel-axis theorem a second time to obtain an expression for I_C:

$$I_C = \frac{1}{2}MR^2 - D^2M + Mr^2 = M\left(\frac{1}{2}R^2 - D^2 + r^2\right) \quad (2)$$

Apply the law of cosines to obtain:

$$r^2 = R^2 + D^2 - 2RD\cos\theta$$

Substitute for r^2 in equation (2) to obtain:

$$I_C = M\left(\frac{1}{2}R^2 - D^2 + R^2 + D^2 - 2RD\cos\theta\right) = MR^2\left(\frac{3}{2} - 2\frac{D}{R}\cos\theta\right)$$

Substitute for h and I_C in equation (1):

$$E = MgD(1-\cos\theta) + \frac{1}{2}MR^2\left(\frac{3}{2} - 2\frac{D}{R}\cos\theta\right)\left(\frac{d\theta}{dt}\right)^2$$

Use the small angle approximation $\cos\theta \approx 1 - \frac{1}{2}\theta^2$ to obtain:

$$E = \frac{1}{2}MgD\theta^2 + \frac{1}{2}MR^2\left(\frac{3}{2} - \frac{D}{R}\left[2-\theta^2\right]\right)\left(\frac{d\theta}{dt}\right)^2$$

Because $\theta^2 << 2$, we can neglect the θ^2 in the square brackets to obtain:

$$E = \frac{1}{2}MgD\theta^2 + \frac{1}{2}MR^2\left(\frac{3}{2} - 2\frac{D}{R}\right)\left(\frac{d\theta}{dt}\right)^2$$

Differentiating both sides with respect to time yields:

$$0 = MgD\theta\frac{d\theta}{dt} + MR^2\left(\frac{3}{2} - 2\frac{D}{R}\right)\left(\frac{d\theta}{dt}\right)\left(\frac{d^2\theta}{dt^2}\right),$$

$$R^2\left(\frac{3}{2} - 2\frac{D}{R}\right)\left(\frac{d^2\theta}{dt^2}\right) + gD\theta = 0,$$

and

$$\frac{d^2\theta}{dt^2} + \frac{gD}{R^2\left(\frac{3}{2} - 2\frac{D}{R}\right)}\theta = 0,$$

the differential equation of simple harmonic motion with $\omega^2 = \frac{gD}{R^2\left(\frac{3}{2} - 2\frac{D}{R}\right)}$.

Substitute for D to obtain:

$$\omega^2 = \frac{\frac{4}{3\pi}}{\left(\frac{3}{2} - \frac{8}{3\pi}\right)}\frac{g}{R} = \left(\frac{8}{9\pi - 16}\right)\frac{g}{R}$$

Express the period of the motion in terms of ω and simplify to obtain:

$$T = \frac{2\pi}{\omega} = 2\pi\sqrt{\left(\frac{9\pi - 16}{8}\right)\frac{R}{g}}$$

$$= \boxed{7.78\sqrt{\frac{R}{g}}}$$

***122** •••

Picture the Problem The net force acting on the particle as it moves in the tunnel is the x-component of the gravitational force acting on it. We can find the period of the particle from the angular frequency of its motion. We can apply Newton's 2nd law to the particle in order to express ω in terms of the radius of the earth and the acceleration due to gravity at the surface of the earth.

(a) From the figure we see that:

$$F_x = F_r \sin\theta = -\frac{GmM_E}{R_E^3}r\frac{x}{r}$$

$$= \boxed{-\frac{GmM_E}{R_E^3}x}$$

Because this force is a linear restoring force, the motion of the particle is simple harmonic motion.

(*b*) Express the period of the particle as a function of its angular frequency:

$$T = \frac{2\pi}{\omega} \qquad (1)$$

Apply $\sum F_x = ma_x$ to the particle:

$$-\frac{GmM_E}{R_E^3}x = ma$$

Solve for *a*:

$$a = -\frac{GM_E}{R_E^3}x = -\omega^2 x$$

where

$$\omega = \sqrt{\frac{GM_E}{R_E^2}}$$

Use $GM_E = gR_E^2$ to simplify ω:

$$\omega = \sqrt{\frac{gR_E^2}{R_E^3}} = \sqrt{\frac{g}{R_E}}$$

Substitute in equation (1) to obtain:

$$T = \frac{2\pi}{\sqrt{\dfrac{g}{R_E}}} = \boxed{2\pi\sqrt{\frac{R_E}{g}}}$$

Substitute numerical values and evaluate *T*:

$$T = 2\pi\sqrt{\frac{6.37\times10^6\text{ m}}{9.81\text{ m/s}^2}} = 5.06\times10^3\text{ s}$$

$$= \boxed{84.4\text{ min}}$$

123 •••

Picture the Problem The amplitude of a damped oscillator decays with time according to $A = A_0e^{-(b/2m)t}$. We can find *b*/2*m* from $\omega' = \omega_0\sqrt{1-\left(\dfrac{b}{2m\omega_0}\right)^2}$ and then substitute in the amplitude equation to find the factor by which the amplitude is decreased during each oscillation. We'll use our result from (*a*), together with the dependence of the energy of the oscillator on the square of its amplitude, to find the factor by which its energy is reduced during each oscillation.

(*a*) Express the variation in amplitude with time:

$$A = A_0e^{-(b/2m)t} \qquad (1)$$

Relate the damped and undamped frequencies of the oscillator:

$$\omega' = \omega_0\sqrt{1-\left(\frac{b}{2m\omega_0}\right)^2} \qquad (14\text{-}46)$$

Solve for $b/2m$:

$$\frac{b}{2m} = \omega_0\sqrt{1-\frac{\omega'^2}{\omega_0^2}} = \omega_0\sqrt{1-(0.9)^2}$$
$$= 0.436\omega_0$$

Find the period of the damped oscillations:

$$T = \frac{2\pi}{\omega'} = \frac{2\pi}{0.9\omega_0}$$

Substitute in equation (1) with $t = T$ to obtain:

$$\frac{A}{A_0} = e^{-(0.436\omega_0)\left(\frac{2\pi}{0.9\omega_0}\right)} = e^{-3.04}$$
$$= \boxed{0.0478}$$

(*b*) Express the energy of the oscillator at time $t = 0$:

$$E_0 = \tfrac{1}{2}kA_0^2$$

Express the energy of the oscillator at time $t = T$:

$$E = \tfrac{1}{2}kA^2$$

Divide the second of these equations by the first, simplify, and substitute to evaluate E/E_0:

$$\frac{E}{E_0} = \frac{A^2}{A_0^2} = \left(\frac{A}{A_0}\right)^2 = (0.0477)^2$$
$$= \boxed{0.00228}$$

124 •••

Picture the Problem We can differentiate Equation 14-52 twice and substitute *x* and d^2x/dt^2 in Equation 14-51 to determine the condition that must be satisfied in order for Equation 14-52 to be a solution of Equation 14-51.

The differential equation of motion is Equation 14-51:

$$m\frac{d^2x}{dt^2} + b\frac{dx}{dt} + m\omega_0^2 x = F_0\cos\omega t$$

Its proposed solution is Equation 14-52:

$$x = A\cos(\omega t - \delta)$$

Obtain the first and second derivatives of *x*:

$$\frac{dx}{dt} = -A\omega\sin(\omega t - \delta)$$

and

$$\frac{d^2x}{dt^2} = -A\omega^2\cos(\omega t - \delta)$$

Substitute in the differential equation to obtain:

$$-mA\omega^2\cos(\omega t - \delta) - bA\omega\sin(\omega t - \delta) + m\omega_0^2 A\cos(\omega t - \delta) = F_0\cos\omega t$$

Using trigonometric identities, expand $\cos(\omega t - \delta)$ and $\sin(\omega t - \delta)$ to obtain:

$$-mA\omega^2(\cos\omega t\cos\delta + \sin\omega t\sin\delta) - bA\omega(\sin\omega t\cos\delta - \cos\omega t\sin\delta)$$
$$+ m\omega_0^2 A(\cos\omega t\cos\delta + \sin\omega t\sin\delta) = F_0\cos\omega t$$

Factor $mA(\cos\omega t\cos\delta + \sin\omega t\sin\delta)$ from the first and third terms to obtain:

$$mA(\omega_0^2 - \omega^2)(\cos\omega t\cos\delta + \sin\omega t\sin\delta) - bA\omega(\sin\omega t\cos\delta - \cos\omega t\sin\delta) = F_0\cos\omega t$$

Factor $\cos\omega t\cos\delta$ from the first term on the left-hand side of the equation and $\sin\omega t\cos\delta$ from the 2nd term:

$$mA(\omega_0^2 - \omega^2)(\cos\omega t\cos\delta)\left(1 + \frac{\sin\omega t\sin\delta}{\cos\omega t\cos\delta}\right) - bA\omega(\sin\omega t\cos\delta)\left(1 - \frac{\cos\omega t\sin\delta}{\sin\omega t\cos\delta}\right)$$
$$= F_0\cos\omega t$$

Simplify to obtain:

$$mA(\omega_0^2 - \omega^2)(\cos\omega t\cos\delta)(1 + \tan\omega t\tan\delta) - bA\omega(\sin\omega t\cos\delta)\left(1 - \frac{\tan\delta}{\tan\omega t}\right)$$
$$= F_0\cos\omega t$$

Divide both sides of the equation by $m(\omega_0^2 - \omega^2)$:

$$A(\cos\omega t\cos\delta)(1 + \tan\omega t\tan\delta) - \frac{bA\omega}{m(\omega_0^2 - \omega^2)}(\sin\omega t\cos\delta)\left(1 - \frac{\tan\delta}{\tan\omega t}\right)$$
$$= \frac{F_0}{m(\omega_0^2 - \omega^2)}\cos\omega t$$

The phase constant for a driven oscillator is given by Equation 14-54:

$$\tan\delta = \frac{b\omega}{m(\omega_0^2 - \omega^2)}$$

Substitute for $\tan\delta$:

$$A(\cos\omega t\cos\delta)\left(1+\tan\omega t\frac{b\omega}{m(\omega_0^2-\omega^2)}\right)-\frac{bA\omega}{m(\omega_0^2-\omega^2)}(\sin\omega t\cos\delta)$$
$$\times\left(1-\frac{\frac{b\omega}{m(\omega_0^2-\omega^2)}}{\tan\omega t}\right)=\frac{F_0}{m(\omega_0^2-\omega^2)}\cos\omega t$$

Simplify to obtain:

$$A(\cos\omega t\cos\delta)(1+\tan^2\delta)=\frac{F_0}{m(\omega_0^2-\omega^2)}\cos\omega t$$

Use the trigonometric identity $1+\tan^2\delta=\frac{1}{\cos^2\delta}$:

$$A(\cos\omega t\cos\delta)\frac{1}{\cos^2\delta}=\frac{F_0}{m(\omega_0^2-\omega^2)}\cos\omega t$$

Simplify to obtain:

$$A\cos\omega t=\frac{F_0\cos\delta}{m(\omega_0^2-\omega^2)}\cos\omega t$$

Thus $x=A\cos(\omega t-\delta)$ is a solution to Equation 14-51 provided:

$$\boxed{A=\frac{F_0\cos\delta}{m(\omega_0^2-\omega^2)}}$$

***125** •••

Picture the Problem We can follow the step-by-step instructions provided in the problem statement to obtain the desired results.

(*a*) Express the average power delivered by a driving force to a driven oscillator:

$P=\vec{F}\cdot\vec{v}=Fv\cos\theta$

or, because θ is 0°,

$P=Fv$

Express *F* as a function of time:

$F=F_0\cos\omega t$

Express the position of the driven oscillator as a function of time:

$x=A\cos(\omega t-\delta)$

Differentiate this expression with respect to time to express the velocity of the oscillator as a function of time:

$$v = -A\omega\sin(\omega t - \delta)$$

Substitute to express the average power delivered to the driven oscillator:

$$P = (F_0 \cos \omega t)[-A\omega\sin(\omega t - \delta)]$$
$$= \boxed{-A\omega F_0 \cos \omega t \sin(\omega t - \delta)}$$

(*b*) Expand $\sin(\omega t - \delta)$ to obtain:

$$\sin(\omega t - \delta) = \sin \omega t \cos \delta - \cos \omega t \sin \delta$$

Substitute in your result from (*a*) and simplify to obtain:

$$P = -A\omega F_0 \cos \omega t(\sin \omega t \cos \delta - \cos \omega t \sin \delta)$$
$$= \boxed{A\omega F_0 \sin \delta \cos^2 \omega t - A\omega F_0 \cos \delta \cos \omega t \sin \omega t}$$

(*c*) Integrate $\sin\theta\cos\theta$ over one period to determine $\langle \sin\theta\cos\theta \rangle$:

$$\langle \sin\theta\cos\theta \rangle = \frac{1}{2\pi}\left[\int_0^{2\pi} \sin\theta\cos\theta d\theta\right]$$
$$= \frac{1}{2\pi}\left[\frac{1}{2}\sin^2\theta\Big|_0^{2\pi}\right]$$
$$= 0$$

Integrate $\cos^2\theta$ over one period to determine $\langle \cos^2\theta \rangle$:

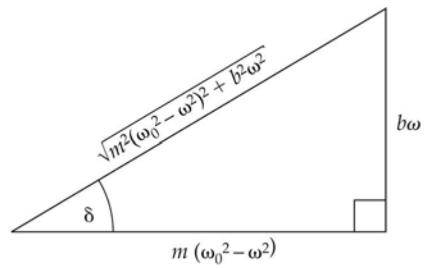
$$\langle \cos^2\theta \rangle = \frac{1}{2\pi}\int_0^{2\pi} \cos^2\theta d\theta$$
$$= \frac{1}{2\pi}\left[\frac{1}{2}\int_0^{2\pi}(1+\cos 2\theta)d\theta\right]$$
$$= \frac{1}{2\pi}\left[\tfrac{1}{2}\int_0^{2\pi} d\theta + \tfrac{1}{2}\int_0^{2\pi}\cos 2\theta d\theta\right]$$
$$= \frac{1}{2\pi}(\pi + 0) = \frac{1}{2}$$

Substitute and simplify to express P_{av}:

$$P_{av} = A\omega F_0 \sin\delta\langle \cos^2 \omega t\rangle - A\omega F_0 \cos\delta\langle \cos\omega t \sin \omega t\rangle$$
$$= \tfrac{1}{2}A\omega F_0 \sin\delta - A\omega F_0 \cos\delta(0)$$
$$= \boxed{\tfrac{1}{2}A\omega F_0 \sin\delta}$$

(*d*) Construct a triangle that is consistent with

$$\tan\delta = \frac{b\omega}{m\left(\omega_0^2 - \omega^2\right)}:$$



Using the triangle, express sin*δ*:

$$\boxed{\sin\delta = \frac{b\omega}{\sqrt{m^2\left(\omega_0^2-\omega^2\right)^2 + b^2\omega^2}}}$$

Using equation 14-53, reduce this expression to the simpler form:

$$\boxed{\sin\delta = \frac{b\omega A}{F_0}}$$

(*e*) Solve $\sin\delta = \dfrac{b\omega A}{F_0}$ for *ω*:

$$\omega = \frac{F_0}{bA}\sin\delta$$

Substitute in the expression for P_{av} to eliminate *ω*:

$$\boxed{P_{av} = \frac{F_0^2}{2b}\sin^2\delta}$$

Substitute for $\sin\delta$ from (*d*) to obtain Equation 14-55:

$$\boxed{P_{av} = \frac{1}{2}\left[\frac{b\omega^2 F_0^2}{m^2\left(\omega_0^2-\omega^2\right)^2 + b^2\omega^2}\right]}$$

126 •••

Picture the Problem We can follow the step-by-step instructions given in the problem statement to derive the given results.

(*a*) Express the condition on the denominator of Equation 14-55 when the power input is half its maximum value:

$$m^2\left(\omega_0^2-\omega^2\right)^2 + b^2\omega^2 = 2b^2\omega_0^2$$

and, for a sharp resonance,

$$m^2\left(\omega_0^2-\omega^2\right)^2 \approx b^2\omega_0^2$$

Factor the difference of two squares to obtain:

$$m^2\left[(\omega_0-\omega)(\omega_0+\omega)\right]^2 \approx b^2\omega_0^2$$

or

$$\boxed{m^2(\omega_0-\omega)^2(\omega_0+\omega)^2 \approx b^2\omega_0^2}$$

(*b*) Use the approximation $\omega + \omega_0 \approx 2\omega_0$ to obtain:

$$m^2(\omega_0-\omega)^2(2\omega_0)^2 \approx b^2\omega_0^2$$

Solve for $\omega_0 - \omega$:

$$\omega_0 - \omega = \boxed{\pm\frac{b}{2m}} \qquad (1)$$

(c) Using its definition, express Q:

$$Q = \frac{\omega_0 m}{b}$$

Solve for b:

$$b = \boxed{\frac{\omega_0 m}{Q}}$$

(d) Substitute for b in equation (1) to obtain:

$$\omega_0 - \omega = \pm\frac{\omega_0}{2Q}$$

Solve for ω:

$$\omega = \omega_0 \pm \frac{\omega_0}{2Q}$$

Express the two values of ω:

$$\omega_+ = \boxed{\omega_0 + \frac{\omega_0}{2Q}}$$

and

$$\omega_- = \boxed{\omega_0 - \frac{\omega_0}{2Q}}$$

Remarks: Note that the width of the resonance at half-power is $\Delta\omega = \omega_+ - \omega_- = \omega_0/Q$, in agreement with Equation 14-49.

127 •••

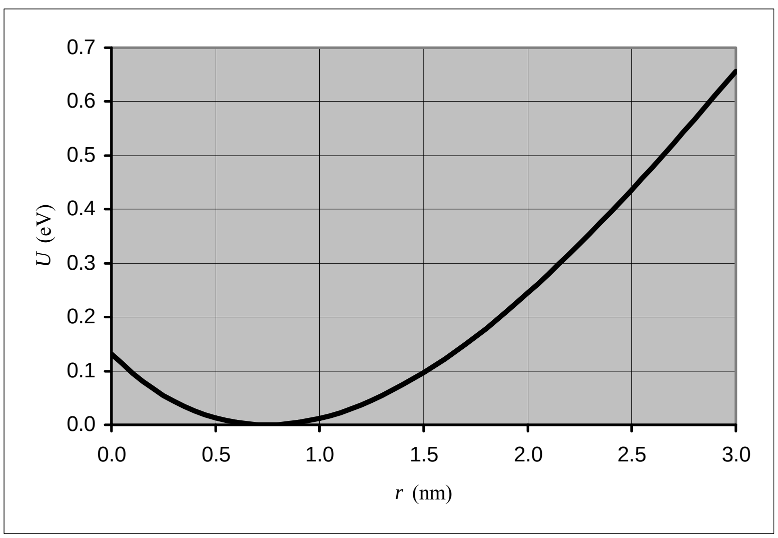
Picture the Problem We can find the equilibrium separation for the Morse potential by setting $dU/dr = 0$ and solving for r. The second derivative of U will give the "spring constant" for small displacements from equilibrium. In (c), we can use $\omega = \sqrt{k/\mu}$, where k is our result from (b) and μ is the reduced mass of a homonuclear diatomic molecule, to find the oscillation frequency of the molecule.

(a) A spreadsheet program to calculate the Morse potential as a function of r is shown below. The constants and cell formulas used to calculate the potential are shown in the table.

Cell	Content/Formula	Algebraic Form
B1	5	D
B2	0.2	β
C9	C8 + 0.1	$r + \Delta r$
D8	$B$1*(1–EXP(–$B$2*(C8–$B$3)))^2	$D\left[1 - e^{-\beta(r-r_0)}\right]^2$

	A	B	C	D
1	D=	5	eV	
2	Beta=	0.2	nm^{-1}	
3	r0=	0.75	nm	
4				
5				
6			r	U(r)
7			(nm)	(eV)
8			0.0	0.13095
9			0.1	0.09637
10			0.2	0.06760
11			0.3	0.04434
12			0.4	0.02629
235			22.7	4.87676
236			22.8	4.87919
237			22.9	4.88156
238			23.0	4.88390
239			23.1	4.88618

The graph shown below was plotted using the data from columns C (*r*) and D (*U*(*r*)).



(*b*) Differentiate the Morse potential with respect to r to obtain:

$$\frac{dU}{dr}=\frac{d}{dr}\left\{D\left[1-e^{-\beta(r-r_0)}\right]^2\right\}$$
$$=-2\beta D\left[1-e^{-\beta(r-r_0)}\right]$$

Set this derivative equal to zero for extrema:

$$-2\beta D\left[1-e^{-\beta(r-r_0)}\right]=0$$

Solve for r to obtain: $r = \boxed{r_0}$

Evaluate the second derivative of $U(r)$ to obtain:

$$\frac{d^2U}{dr^2} = \frac{d}{dr}\left\{-2\beta D\left[1 - e^{-\beta(r-r_0)}\right]\right\} = 2\beta^2 D e^{-\beta(r-r_0)}$$

Evaluate this derivative at $r = r_0$:

$$\left.\frac{d^2U}{dr^2}\right|_{r=r_0} = 2\beta^2 D \qquad (1)$$

Recall that the potential function for a simple harmonic oscillator is: $U = \frac{1}{2}kx^2$

Differentiate this expression twice to obtain:

$$\frac{d^2U}{dx^2} = k$$

By comparison with equation (1) we have: $k = \boxed{2\beta^2 D}$

(*c*) Express the oscillation frequency of the diatomic molecule:

$$\omega = \sqrt{\frac{k}{\mu}}$$

where μ is the reduced mass of the molecule.

Express the reduced mass of the homonuclear diatomic molecule:

$$\mu = \frac{m_1 m_2}{m_1 + m_2} = \frac{m^2}{2m} = \frac{m}{2}$$

Substitute and simplify to obtain:

$$\omega = \sqrt{\frac{2\beta^2 D}{\frac{m}{2}}} = \boxed{2\beta\sqrt{\frac{D}{m}}}$$

Remarks: An alternative approach in (*b*) is the expand the Morse potential in a Taylor series

$$U(r) = U(r_0) + (r - r_0)U'(r_0) + \frac{1}{2!}(r - r_0)^2 U''(r_0) + \text{higher order terms}$$

to obtain $U(r) \approx \beta^2 D(r - r_0)^2$**. Comparing this expression to the energy of a spring-and-mass oscillator we see that, as was obtained above,** $k = 2\beta^2 D$**.**

Chapter 15
Wave Motion

Conceptual Problems

***1 •**

Determine the Concept The speed of a transverse wave on a rope is given by $v = \sqrt{F/\mu}$ where F is the tension in the rope and μ is its linear density. The waves on the rope move faster as they move up because the tension increases due to the weight of the rope below.

2 •

Determine the Concept The distance between successive crests is one wavelength and the time between successive crests is the period of the wave motion. Thus, T = 0.2 s and $f = 1/T = 5$ Hz. $\boxed{(b)\text{ is correct.}}$

3 •

Picture the Problem True. The energy per unit volume (the average energy density) is given by $\eta_{av} = \frac{1}{2}\rho\omega^2 s_0^2$ where s_0 is the displacement amplitude.

4 •

Determine the Concept At every point along the rope the wavelength, speed, and frequency of the wave are related by $\lambda = v/f$. The speed of the wave, in turn, is given by $v = \sqrt{F/\mu}$ where F is the tension in the rope and μ is its linear density. Due to the weight of the rope below, the tension is greater at the top and the speed of the wave is also greater at the top. Because $\lambda \propto v$, the wavelength is greater at the top.

***5 •**

Determine the Concept The speed of the wave v on the bullwhip varies with the tension F in the whip and its linear density μ according to $v = \sqrt{F/\mu}$. As the whip tapers, the wave speed in the tapered end increases due to the decrease in the mass density, so the wave travels faster.

6 •

Picture the Problem The intensity level of a sound wave β, measured in decibels, is given by $\beta = (10\,\text{dB})\log(I/I_0)$ where $I_0 = 10^{-12}$ W/m^2 is defined to be the threshold of hearing.

Express the intensity of the 60-dB sound:

$$60\text{dB} = (10\,\text{dB})\log\frac{I_{60}}{I_0} \Rightarrow I_{60} = 10^6 I_0$$

Express the intensity of the 30-dB sound:

$$30\,\text{dB} = (10\,\text{dB})\log\frac{I_{30}}{I_0} \Rightarrow I_{30} = 10^3 I_0$$

Because $I_{60} = 10^3 I_{30}$:

$$\boxed{\text{The statement is false.}}$$

7 •

Determine the Concept No. Because the source and receiver are at rest relative to each other, there is no relative motion of the source and receiver and there will be no Doppler shift in frequency.

8 •

Determine the Concept Because there is no relative motion of the source and receiver, there will be no Doppler shift and the observer will hear sound of frequency f_0.

$\boxed{(a)\text{ is correct.}}$

***9** ••

Determine the Concept The light from the companion star will be shifted about its mean frequency periodically due to the relative approach to and recession from the earth of the companion star as it revolves about the black hole.

10 •

Determine the Concept In any medium, the wavelength, frequency, and speed of a wave are related through $\lambda = v/f$. Because the frequency of a wave is determined by its source and is independent of the nature of the medium, if v differs in the two media, the wavelengths will also differ. In this situation, the frequencies are the same but the speeds of propagation are different.

11 •

(*a*) True. The particles that make up the string move at right angles to the direction the wave is propagating.

(*b*) False. Sound waves in air are *longitudinal* waves of compression and rarefaction.

(*c*) False. The speed of sound in air varies with the square root of the absolute temperature. The speed of sound at 20°C is 4% greater than that at 5°C.

12 •

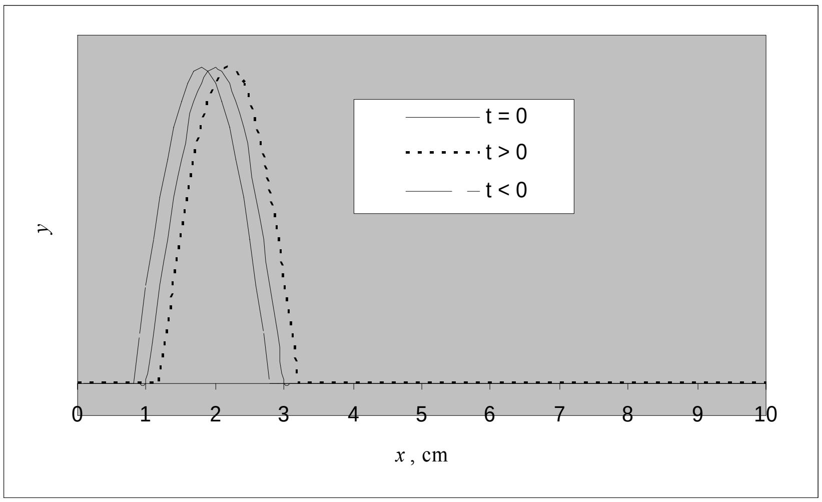
Determine the Concept In any medium, the wavelength, frequency, and speed of a sound wave are related through $\lambda = v/f$. Because the frequency of a wave is determined by its source and is independent of the nature of the medium, if v is greater in water than in air, λ will be greater in water than in air. $\boxed{(a) \text{ is correct.}}$

***13 •**

Determine the Concept There was only one explosion. Sound travels faster in water than air. Abel heard the sound wave in the water first, then, surfacing, heard the sound wave traveling through the air, which took longer to reach him.

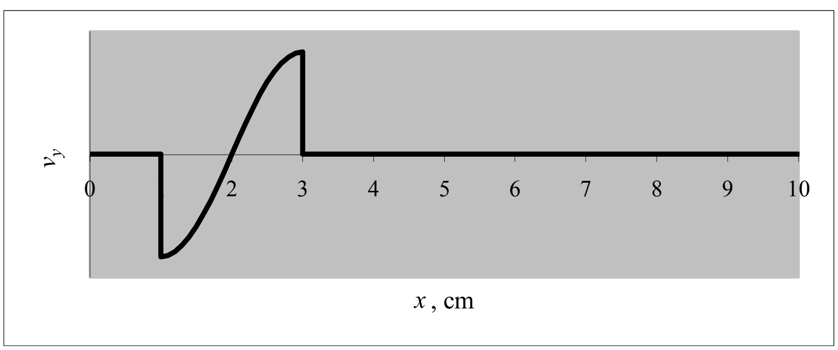
14 ••

Determine the Concept The graph shown below shows the pulse at an earlier time ($-\Delta t$) and later time (Δt). One can see that at $t = 0$, the portion of the string between 1 cm and 2 cm is moving down, the portion between 2 cm and 3 cm is moving up, and the string at $x = 2$ cm is instantaneously at rest.



15 ••

Determine the Concept The velocity of the string at $t = 0$ is shown. Note that the velocity is negative for 1 cm < x < 2 cm and is positive for 2 cm < x < 3 cm.



16 ••

Determine the Concept As the jar is evacuated, the speed of sound inside the jar decreases. Because of the mismatch between the speed of sound inside and outside of the jar, a larger fraction of the sound wave is reflected back into the jar, and a smaller fraction is transmitted through the glass of the bell jar.

***17** ••

Determine the Concept Path C. Because the wave speed is highest in the water, and more of path C is underwater than A or B, the sound wave will spend the least time on path C.

Estimation and Approximation

18 ••

Picture the Problem The rate at which energy is delivered by sound waves is the product of its intensity and the area over which the energy is delivered. We can use the definition of the intensity level of the speech at 1 m to find the intensity of the sound and the formula for the area of a sphere to find the area over which the energy is distributed.

Express the power of human speech as a function of its intensity:

$$P = IA$$

Express the area of a sphere of radius 1 m:

$$A = 4\pi r^2 = 4\pi(1\,\text{m})^2 = 4\pi\,\text{m}^2$$

Use $\beta = (10\,\text{dB})\log(I/I_0)$ to solve for the intensity of the sound at the 65-dB level:

$$65\,\text{dB} = (10\,\text{dB})\log\frac{I}{I_0}$$

and

$$I = 10^{6.5} I_0 = 10^{6.5}\left(10^{-12}\,\text{W/m}^2\right) = 3.16\times10^{-6}\,\text{W/m}^2$$

Substitute and evaluate P:

$$P = \left(3.16\times10^{-6}\,\text{W/m}^2\right)\left(4\pi\,\text{m}^2\right) = \boxed{3.97\times10^{-5}\,\text{W}}$$

19 ••

Picture the Problem Let d represent the distance from the bridge to the water under the assumption that the time for the sound to reach the man is negligible; let t be the elapsed time between dropping the stone and hearing the splash. We'll use a constant-acceleration equation to find the distance to the water in all three parts of the problem, just improving our initial value with corrections taking into account the time required for the sound of the splash to reach the man on the bridge.

(*a*) Using a constant-acceleration equation, relate the distance the stone falls to its time-of-fall:

$$d = v_0 t + \tfrac{1}{2} g t^2$$

or, because $v_0 = 0$,

$$d = \tfrac{1}{2} g t^2$$

Substitute numerical values and evaluate *d*:

$$d = \tfrac{1}{2}\left(9.81\,\text{m/s}^2\right)\left(4\,\text{s}\right)^2 = \boxed{78.5\,\text{m}}$$

(*b*) Express the actual distance to the water *d′* in terms of a time correction Δ*t*:

$$d' = \tfrac{1}{2} g\left(t - \Delta t\right)^2$$

Express Δ*t*:

$$\Delta t = \frac{d}{v_\text{s}}$$

Substitute to obtain:

$$d' = \tfrac{1}{2} g\left(t - \frac{d}{v_\text{s}}\right)^2$$

Substitute numerical values and evaluate *d′*:

$$d' = \tfrac{1}{2}\left(9.81\,\text{m/s}^2\right)\left(4\,\text{s} - \frac{78.5\,\text{m}}{340\,\text{m/s}}\right)^2$$

$$= \boxed{69.7\,\text{m}}$$

(*c*) Express the total time for the rock to fall and the sound to return to the man:

$$\Delta t = \Delta t_\text{falling rock} + \Delta t_\text{sound} = \sqrt{\frac{2d}{\text{g}}} + \frac{d}{v_\text{s}}$$

Rewrite the equation in quadratic form:

$$d^2 - 2v_\text{s}^2\left(\frac{1}{g} + \frac{\Delta t}{v_\text{s}}\right)d + v_\text{s}^2\left(\Delta t\right)^2 = 0$$

Substitute numerical values to obtain:

$$d^2 - \left(2.63\times10^4\,\text{m}\right)d + 1.85\times10^6\,\text{m}^2 = 0$$

Solve for the positive value of *d*:

$d = \boxed{70.5\,\text{m}}$ … about 1% larger than our result in part (*b*) and 11% smaller than our first approximation in (*a*).

***20 ••**

Picture the Problem You can use a protractor to measure the angle of the shock cone and then estimate the speed of the bullet using $\sin\theta = v/u$. The speed of sound in helium at room temperature (293 K) is 977 m/s.

Relate the speed of the bullet u to the speed of sound v in helium and the angle of the shock cone θ:

$$\sin\theta = \frac{v}{u}$$

Solve for u:

$$u = \frac{v}{\sin\theta}$$

Measure θ to obtain:

$$\theta \approx 70°$$

Substitute numerical values and evaluate u:

$$u = \frac{977\,\text{m/s}}{\sin 70°} = \boxed{1.04\,\text{km/s}}$$

21 ••

Picture the Problem Let d be the distance to the townhouses. We can relate the speed of sound to the distance to the townhouses to the frequency of the clapping for which no echo is heard.

Relate the speed of sound to the distance it travels to the townhouses and back to the elapsed time:

$$v = \frac{2d}{\Delta t}$$

Express d in terms of the number of strides and distance covered per stride:

$$d = (30\,\text{strides})(1.8\,\text{m/stride}) = 54\,\text{m}$$

Relate the elapsed time Δt to the frequency f of the clapping:

$$\Delta t = \frac{1}{f} = \frac{1}{2.5\,\text{claps/s}} = 0.4\,\text{s}$$

Substitute numerical values and evaluate v:

$$v = \frac{2(54\,\text{m})}{0.4\,\text{s}} = \boxed{270\,\text{m/s}}$$

Express the percent difference between this result and 340 m/s:

$$\frac{340\,\text{m/s} - 270\,\text{m/s}}{340\,\text{m/s}} = \boxed{20.6\%}$$

Speed of Waves

22 •

Picture the Problem The speed of sound in a fluid is given by $v = \sqrt{B/\rho}$ where B is the bulk modulus of the fluid and ρ is its density.

(*a*) Express the speed of sound in water in terms of its bulk modulus:

$$v = \sqrt{\frac{B}{\rho}}$$

Substitute numerical values and evaluate v:

$$v = \sqrt{\frac{2.0\times10^{9}\ \text{N/m}^2}{10^{3}\ \text{kg/m}^3}} = \boxed{1.41\,\text{km/s}}$$

(*b*) Solve $v = \sqrt{B/\rho}$ for *B*:

$$B = \rho v^2$$

Substitute numerical values and evaluate *B*:

$$B = \left(13.6\times10^3\ \text{kg/m}^3\right)\left(1410\,\text{m/s}\right)^2 = \boxed{2.70\times10^{10}\ \text{N/m}^2}$$

***23** •

Picture the Problem The speed of sound in a gas is given by $v = \sqrt{\gamma RT/M}$ where *R* is the gas constant, *T* is the absolute temperature, *M* is the molecular mass of the gas, and γ is a constant that is characteristic of the particular molecular structure of the gas. Because hydrogen gas is diatomic, γ = 1.4.

Express the dependence of the speed of sound in hydrogen gas on the absolute temperature:

$$v = \sqrt{\frac{\gamma RT}{M}}$$

Substitute numerical values and evaluate *v*:

$$v = \sqrt{\frac{1.4\left(8.314\,\text{J/mol}\cdot\text{K}\right)\left(300\,\text{K}\right)}{2\times10^{-3}\,\text{kg/mol}}} = \boxed{1.32\,\text{km/s}}$$

24 •

Picture the Problem The speed of a transverse wave pulse on a wire is given by $v = \sqrt{F/\mu}$ where *F* is the tension in the wire, *m* is its mass, *L* is its length, and μ is its mass per unit length.

Express the dependence of the speed of the pulse on the tension in the wire:

$$v = \sqrt{\frac{F}{\mu}}$$

where μ is the mass per unit length of the wire.

Substitute numerical values and evaluate *v*:

$$v = \sqrt{\frac{F}{m/L}} = \sqrt{\frac{900\,\text{N}}{0.1\,\text{kg}/7\,\text{m}}} = \boxed{251\,\text{m/s}}$$

25 •

Picture the Problem The speed of transverse waves on a wire is given by $v = \sqrt{F/\mu}$ where *F* is the tension in the wire, *m* is its mass, *L* is its length, and μ is its mass per unit length.

Express the dependence of the speed of the pulse on the tension in the wire and the linear density of the wire:

$$v = \sqrt{\frac{F}{m/L}}$$

Solve for *m*:

$$m = \frac{FL}{v^2}$$

Substitute numerical values and evaluate *m*:

$$m = \frac{(550\,\text{N})(0.8\,\text{m})}{(150\,\text{m/s})^2} = \boxed{19.6\,\text{g}}$$

***26** •

Picture the Problem The speed of a wave pulse on a wire is given by $v = \sqrt{F/\mu}$ where F is the tension in the wire, m is its mass, L is its length, and μ is its mass per unit length.

(*a*) Doubling the length while keeping the mass per unit length constant does not change the linear density:

$$v = \boxed{20\,\text{m/s}}$$

(*b*) Because *v* depends of $\sqrt{F}$, doubling the tension increases *v* by a factor of $\sqrt{2}$:

$$v = \sqrt{2}(20\,\text{m/s}) = \boxed{28.3\,\text{m/s}}$$

(*c*) Because *v* depends on $1/\sqrt{\mu}$, doubling μ reduces *v* by a factor of $\sqrt{2}$:

$$v = \frac{20\,\text{m/s}}{\sqrt{2}} = \boxed{14.1\,\text{m/s}}$$

27 •

Picture the Problem The speed of a transverse wave on the piano wire is given by $v = \sqrt{F/\mu}$ where F is the tension in the wire, m is its mass, L is its length, and μ is its mass per unit length.

(*a*) The speed of transverse waves on the wire is given by:

$$v = \sqrt{\frac{F}{\mu}} = \sqrt{\frac{F}{m/L}}$$

Substitute numerical values and evaluate *v*:

$$v = \sqrt{\frac{500\,\text{N}}{(0.005\,\text{kg})/(0.7\,\text{m})}} = \boxed{265\,\text{m/s}}$$

(*b*) Letting m' represent the mass of the wire when copper has been wrapped around the steel wire, express Δm, the amount of copper wire required:

$$\Delta m = m' - m$$

Express the new wave speed v':

$$v' = \sqrt{\frac{F}{m'/L}}$$

Express the ratio of the speed of the waves in part (*a*) to the reduced wave speed:

$$\frac{v}{v'} = 2 = \frac{\sqrt{\frac{F}{m/L}}}{\sqrt{\frac{F}{m'/L}}} = \sqrt{\frac{m'}{m}}$$

Solve for and evaluate m':

$$m' = 4m$$

Substitute to obtain:

$$\Delta m = m' - m = 4m - m = 3(5\,\text{g}) = \boxed{15.0\,\text{g}}$$

28 ••

Picture the Problem We can estimate the accuracy of this procedure by comparing the estimated distance to the actual distance. Whether a correction for the time it takes the light to reach you is important can be decided by comparing the times required for light and sound to travel a given distance.

(*a*) Convert 340 m/s to km/s:

$$v = 340\,\frac{\text{m}}{\text{s}} \times \frac{1\,\text{km}}{1000\,\text{m}} = \boxed{0.340\,\text{km/s}}$$

(*b*) Express the fractional error in the procedure:

$$\frac{\Delta s}{s} = \frac{s - s_{\text{estimated}}}{s} = \frac{0.340t - 0.333t}{0.340t} = \frac{0.007}{0.340} = \boxed{2.06\%}$$

(*c*) Compare the time required for light to travel 1 km to the time required for sound to travel the same distance:

$$\frac{\Delta t_{\text{light}}}{\Delta t_{\text{sound}}} = \frac{\frac{1\,\text{km}}{c}}{\frac{1\,\text{km}}{v}} = \frac{v}{c} = \frac{340\,\text{m/s}}{3\times10^{8}\,\text{m/s}} \approx 10^{-6}$$

Because this fraction is so small, a correction for the time for light to reach you is not important.

***29** ••

Picture the Problem The speed of a transverse wave on a string is given by $v=\sqrt{F/\mu}$ where F is the tension in the wire and μ is its linear density. We can differentiate this expression with respect to F and then separate the variables to show that the differentials satisfy $dv/v=\frac{1}{2}dF/F$. We'll approximate the differential quantities to determine by how much the tension must be changed to increase the speed of the wave to 312 m/s.

(*a*) Evaluate *dv*/*dF*:

$$\frac{dv}{dF}=\frac{d}{dF}\left[\sqrt{\frac{F}{\mu}}\right]=\frac{1}{2}\sqrt{\frac{1}{F\mu}}=\frac{1}{2}\cdot\frac{v}{F}$$

Separate the variables to obtain:

$$\boxed{\frac{dv}{v}=\frac{1}{2}\frac{dF}{F}}$$

(*b*) Solve for *dF*:

$$dF=2F\frac{dv}{v}$$

Approximate *dF* with Δ*F* and *dv* with Δ*v* to obtain:

$$\Delta F=2F\frac{\Delta v}{v}$$

Substitute numerical values and evaluate Δ*F*:

$$\Delta F=2(500\,\text{N})\frac{12\,\text{m/s}}{300\,\text{m/s}}=\boxed{40.0\,\text{N}}$$

30 ••

Picture the Problem The speed of sound in a gas is given by $v=\sqrt{\gamma RT/M}$ where R is the gas constant, T is the absolute temperature, M is the molecular mass of the gas, and γ is a constant that is characteristic of the particular molecular structure of the gas. We can differentiate this expression with respect to T and then separate the variables to show that the differentials satisfy $dv/v=\frac{1}{2}dT/T$. We'll approximate the differential quantities to determine the percentage change in the velocity of sound when the temperature increases from 0 to 27°C. Lacking information regarding the nature of the gas, we can express the ratio of the speeds of sound at 300 K and 273 K to obtain an expression that involves just the temperatures.

(*a*) Evaluate *dv*/*dT*:

$$\frac{dv}{dT}=\frac{d}{dT}\left[\sqrt{\frac{\gamma RT}{M}}\right]=\frac{1}{2}\sqrt{\frac{M}{\gamma RT}}\left(\frac{\gamma R}{M}\right)$$

$$=\frac{1}{2}\frac{v}{T}$$

Separate the variables to obtain:

$$\boxed{\frac{dv}{v}=\frac{1}{2}\frac{dT}{T}}$$

(*b*) Approximate *dT* with Δ*T* and *dv* with Δ*v* and substitute numerical values to obtain:

$$\frac{\Delta v}{v}=\frac{1}{2}\frac{\Delta T}{T}=\frac{1}{2}\left(\frac{27K}{273\text{K}}\right)=\boxed{4.95\%}$$

(*c*) Using a differential approximation, approximate the speed of sound at 300 K:

$$v_{300\,\text{K}}\approx v_{273\,\text{K}}+v_{273\,\text{K}}\frac{\Delta v}{v}$$

$$=v_{273\,\text{K}}\left(1+\frac{\Delta v}{v}\right)$$

Substitute numerical values and evaluate $v_{300\,\text{K}}$:

$$v_{300\,\text{K}}=(331\,\text{m/s})(1+0.0495)=\boxed{347\,\text{m/s}}$$

Use $v=\sqrt{\gamma RT/M}$ to express the speed of sound at 300 K:

$$v_{300\,\text{K}}=\sqrt{\frac{\gamma R(300\,\text{K})}{M}}$$

Use $v=\sqrt{\gamma RT/M}$ to express the speed of sound at 273 K:

$$v_{273\,\text{K}}=\sqrt{\frac{\gamma R(273\,\text{K})}{M}}$$

Divide the first of these equations by the second and solve for and evaluate $v_{300\,\text{K}}$:

$$\frac{v_{300\,\text{K}}}{v_{273\,\text{K}}}=\frac{\sqrt{\frac{\gamma R(300\,\text{K})}{M}}}{\sqrt{\frac{\gamma R(273\,\text{K})}{M}}}=\sqrt{\frac{300}{273}}$$

and

$$v_{300\,\text{K}}=(331\,\text{m/s})\sqrt{\frac{300}{273}}=\boxed{347\,\text{m/s}}$$

Note that these two results agree to three significant figures.

31 •••

Picture the Problem The speed of sound in a gas is given by $v=\sqrt{\gamma RT/M}$ where R is the gas constant, T is the absolute temperature, M is the molecular mass of the gas, and γ

is a constant that is characteristic of the particular molecular structure of the gas. Because $T = t + 273$ K, we can differentiate v with respect to t to show that $dv/dt = \frac{1}{2}(v/T)$.

Evaluate dv/dt:

$$\frac{dv}{dt} = \frac{d}{dt}\left[\sqrt{\frac{\gamma R(t + 273\,\text{K})}{M}}\right] = \frac{1}{2}\sqrt{\frac{M}{\gamma R(t + 273\,\text{K})}}\left(\frac{\gamma R}{M}\right) = \frac{1}{2}\frac{v}{T}$$

Substitute for t to obtain:

$$\frac{dv}{dt} = \frac{1}{2}\left[\frac{v}{t + 273\,\text{K}}\right]$$

Use the approximation

$$v(T) \approx v(T_0) + \left(\frac{dv}{dT}\right)_{T_0} \Delta T$$

to write:

$$v(t) \approx v(0°C) + \frac{1}{2}\left[\frac{v}{t + 273\,\text{K}}\right]t = v(0°C) + \Delta v \qquad (1)$$

where

$$\Delta v = \frac{1}{2}\left[\frac{331\,\text{m/s}}{t + 273\,\text{K}}\right]t$$

For $t << 273$ K:

$$\Delta v \approx \frac{1}{2}\left[\frac{331\,\text{m/s}}{273\,\text{K}}\right]t = (0.606\,\text{m/s}\cdot\text{K})t$$

Substitute in equation (1) to obtain:

$$v(t) = v(0°C) + (0.606\,\text{m/s}\cdot\text{K})t = \boxed{331\,\text{m/s} + (0.606\,\text{m/s}\cdot\text{K})t}$$

32 ••

Picture the Problem Let d be the distance to the munitions plant, v_1 be the speed of sound in air, v_2 be the speed of sound in rock, and Δt be the difference in the arrival times of the sound at the man's apartment. We can express Δt in terms of $t1$ and $t2$ and then express these travel times in terms of the distance d and the speeds of the sound waves in air and in rock to obtain an equation we can solve for the distance from the man's apartment to the munitions plant.

Express the difference in travel times for the sound wave transmitted through air and the sound wave transmitted through the earth:

$$t_1 - t_2 = \Delta t$$

Express the transmission times in terms of the distance traveled and the speeds in the two media:

$$t_1 = \frac{d}{v_1} \text{ and } t_2 = \frac{d}{v_2}$$

Substitute to obtain:

$$\frac{d}{v_1} - \frac{d}{v_2} = \Delta t$$

or

$$d\left(\frac{1}{v_1} - \frac{1}{v_2}\right) = d\left(\frac{v_2 - v_1}{v_1 v_2}\right) = \Delta t$$

Solve for *d*:

$$d = \frac{v_1 v_2}{v_2 - v_1}\Delta t$$

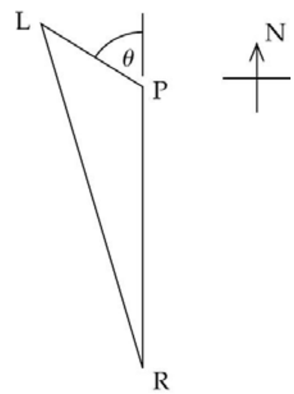
Substitute numerical values and evaluate *d*:

$$d = \frac{(340\,\text{m/s})(3000\,\text{m/s})}{3000\,\text{m/s} - 340\,\text{m/s}}(3\,\text{s})$$

$$= \boxed{1.15\,\text{km}}$$

33 •••

Picture the Problem The locations of the lightning strike (L), dorm room (R), and baseball park (P) are indicated on the diagram. We can neglect the time required for the electromagnetic pulse to reach the source of the radio transmission, which is the ballpark. The angle θ is related to the sides of the triangle through the law of cosines. We're given the distance d_{PR} and can find the other sides of the triangle using the speed of sound and the elapsed times.



Using the law of cosines, relate the angle θ to the distances that make up the sides of the triangle:

$$d_{LR}^2 = d_{LP}^2 + d_{PR}^2 - 2d_{LP}d_{PR}\cos(180° - \theta) = d_{LP}^2 + d_{PR}^2 + 2d_{LP}d_{PR}\cos\theta$$

Solve for θ:

$$\theta = \cos^{-1}\left(\frac{d_{LR}^2 - d_{LP}^2 - d_{PR}^2}{2d_{LP}d_{PR}}\right)$$

Express the distance from the lightning strike to the ball park:

$$d_{LP} = v_s \Delta t_{LP} = (340\,\text{m/s})(2\,\text{s}) = 680\,\text{m}$$

Express the distance from the lightning strike to the dorm room:

$$d_{LR} = v_s \Delta t_{LR} = (340\,\text{m/s})(6\,\text{s}) = 2040\,\text{m}$$

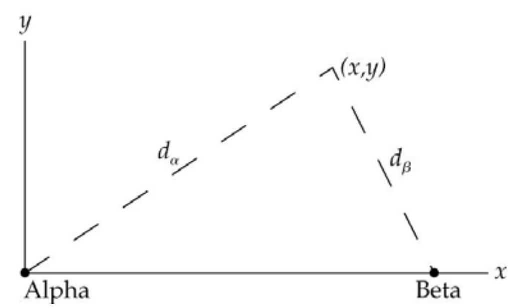
Substitute and evaluate θ:

$$\theta = \cos^{-1}\left(\frac{(2040\,\text{m})^2 - (680\,\text{m})^2 - (1600\,\text{m})^2}{2(680\,\text{m})(1600\,\text{m})}\right) = \pm 58.4°$$

The lightning struck 680 m from the ballpark, 58.4° W (or E) of north.

***34** •••

Picture the Problem Choose a coordinate system in which station Alpha is at the origin and the axes are oriented as shown in the pictorial representation. Because 0.75 mi = 1.21 km, Alpha's coordinates are (0, 0), Beta's are (1.21 km, 0), and those of the lightning strike are (x, y). We can relate the distances from the stations to the speed of sound in air and the times required to hear the thunder at the two stations.



Relate the distance d_α to the position coordinates of Alpha and the lightning strike:

$$x^2 + y^2 = d_\alpha^2 \quad (1)$$

Relate the distance d_β to the position coordinates of Beta and the lightning strike:

$$(x - 1.21\,\text{km})^2 + y^2 = d_\beta^2 \quad (2)$$

Relate the distance d_α to the speed of sound in air v and the time that elapses between seeing the lightning at Alpha and hearing the thunder:

$$d_\alpha = v\Delta t_\alpha = (340\,\text{m/s})(3.4\,\text{s}) = 1156\,\text{m}$$

Relate the distance d_β to the speed of sound in air v and the time that elapses between seeing the lightning at Beta and hearing the thunder:

$$d_\beta = v\Delta t_\beta = (340\,\text{m/s})(2.5\,\text{s}) = 850\,\text{m}$$

Substitute in equations (1) and (2) to obtain:

$$x^2 + y^2 = (1156\,\text{m})^2 = 1.336\,\text{km}^2 \quad (3)$$

and

$$(x - 1.21\,\text{km})^2 + y^2 = (850\,\text{m})^2 = 0.7225\,\text{km}^2 \quad (4)$$

Subtract equation (4) from equation (3) to obtain:

$$x^2 - (x - 1.21\,\text{km})^2 = 1.336\,\text{km}^2 - 0.7225\,\text{km}^2$$

or

$$(2.42\,\text{km})x - (1.21\,\text{km})^2 = 0.6135\,\text{km}^2$$

Solve for x to obtain:

$$x = 0.855\,\text{km}$$

Substitute in equation (3) to obtain:

$$(0.855\,\text{km})^2 + y^2 = 1.336\,\text{km}^2$$

Solve for y, keeping the positive root because the lightning strike is to the north of the stations, to obtain:

$$y = 0.778\,\text{km}$$

The coordinates of the lightning strike are:

$$\boxed{(0.855\,\text{km}, 0.778\,\text{km})}$$

or

$$\boxed{(0.531\,\text{mi}, 0.484\,\text{mi})}$$

35 •••

Picture the Problem The velocity of longitudinal waves on the Slinky is given by $v = \sqrt{B/\rho}$ where B is the bulk modulus of the material from which the slinky is constructed and ρ is its mass per unit volume. The velocity of transverse waves on the slinky is given by $v = \sqrt{F/\mu}$ where F is the tension in the slinky and μ is its mass per unit length. Substitution for B and ρ will lead to $v = L\sqrt{k/m}$ in (*a*) and similar substitutions, together with the assumption that $L_0 << L$ will yield the same result for (*b*).

(*a*) Express the velocity of longitudinal waves on the slinky:

$$v = \sqrt{\frac{B}{\rho}} \quad (1)$$

For the slinky:

$$\rho = \frac{m}{V}$$

and

$$B = -\frac{P}{\Delta V/V} \quad (2)$$

Letting A be the cross-sectional area of the slinky:

$$\rho = \frac{m}{AL} \text{ and } P = -k\frac{\Delta L}{A}$$

Substitute in equation (2) and simplify to obtain:

$$B = k\frac{L}{A}$$

Substitute in equation (1):

$$v = \sqrt{\frac{k\frac{L}{A}}{\frac{m}{AL}}} = \boxed{L\sqrt{\frac{k}{m}}}$$

(*b*) Express the velocity of transverse waves on the slinky:

$$v = \sqrt{\frac{F}{\mu}} \qquad (3)$$

For the slinky:

$$\mu = \frac{m}{L}$$

and

$$F = k\Delta L = k(L - L_0) = kL\left(1 - \frac{L_0}{L}\right)$$
$$\approx kL \text{ if } L_0 << L$$

Substitute in equation (3) to obtain:

$$v = \sqrt{\frac{kL}{\frac{m}{L}}} = \boxed{L\sqrt{\frac{k}{m}}}$$

The Wave Equation

36 •

Picture the Problem The general wave equation is $\frac{\partial^2 y}{\partial x^2} = \frac{1}{v^2}\frac{\partial^2 y}{\partial t^2}$. To show that each of the functions satisfies this equation, we'll need to find their first and second derivatives with respect to *x* and *t* and then substitute these derivatives in the wave equation.

(*a*) Find the first two spatial derivatives of $y(x,t) = k(x + vt)^3$:

$$\frac{\partial y}{\partial x} = 3k(x + vt)^2$$

and

$$\frac{\partial^2 y}{\partial x^2} = 6k(x + vt) \qquad (1)$$

Find the first two temporal derivatives of $y(x,t) = k(x + vt)^3$:

$$\frac{\partial y}{\partial t} = 3kv(x + vt)^2$$

and

$$\frac{\partial^2 y}{\partial t^2} = 6kv^2(x + vt) \qquad (2)$$

Express the ratio of equation (1) to equation (2):

$$\frac{\dfrac{\partial^2 y}{\partial x^2}}{\dfrac{\partial^2 y}{\partial t^2}} = \frac{6k(x + vt)}{6kv^2(x + vt)} = \boxed{\frac{1}{v^2}}$$

confirming that $y(x,t) = k(x + vt)^3$ satisfies the general wave equation.

(*b*) Find the first two spatial derivatives of $y(x,t) = Ae^{ik(x-vt)}$:

$$\frac{\partial y}{\partial x} = ikAe^{ik(x-vt)}$$

and

$$\frac{\partial^2 y}{\partial x^2} = i^2k^2Ae^{ik(x-vt)}$$

or

$$\frac{\partial^2 y}{\partial x^2} = -k^2Ae^{ik(x-vt)} \qquad (3)$$

Find the first two temporal derivatives of $y(x,t) = Ae^{ik(x-vt)}$:

$$\frac{\partial y}{\partial t} = -ikvAe^{ik(x-vt)}$$

and

$$\frac{\partial^2 y}{\partial t^2} = i^2k^2v^2Ae^{ik(x-vt)}$$

or

$$\frac{\partial^2 y}{\partial t^2} = -k^2v^2Ae^{ik(x-vt)} \qquad (4)$$

Express the ratio of equation (3) to equation (4):

$$\frac{\dfrac{\partial^2 y}{\partial x^2}}{\dfrac{\partial^2 y}{\partial t^2}} = \frac{-k^2Ae^{ik(x-vt)}}{-k^2v^2Ae^{ik(x-vt)}} = \boxed{\frac{1}{v^2}}$$

confirming that $y(x,t) = Ae^{ik(x-vt)}$ satisfies the general wave equation.

(*c*) Find the first two spatial derivatives of $y(x,\, t) = \ln k(x - vt)$:

$$\frac{\partial y}{\partial x} = \frac{k}{x - vt}$$

and

$$\frac{\partial^2 y}{\partial x^2} = -\frac{k^2}{(x - vt)^2} \qquad (5)$$

Find the first two temporal derivatives of $y(x,t)=\ln k(x-vt)$:

$$\frac{\partial y}{\partial t}=-\frac{vk}{x-vt}$$

and

$$\frac{\partial^2 y}{\partial t^2}=-\frac{v^2k^2}{(x-vt)^2} \qquad (6)$$

Express the ratio of equation (5) to equation (6):

$$\frac{\dfrac{\partial^2 y}{\partial x^2}}{\dfrac{\partial^2 y}{\partial t^2}}=\frac{-\dfrac{k^2}{(x-vt)^2}}{-\dfrac{v^2k^2}{(x-vt)^2}}=\boxed{\frac{1}{v^2}}$$

confirming that $y(x,t)=\ln k(x-vt)$ satisfies the general wave equation.

***37 •**

Picture the Problem The general wave equation is $\frac{\partial^2 y}{\partial x^2}=\frac{1}{v^2}\frac{\partial^2 y}{\partial t^2}$. To show that $y=A\sin kx\cos\omega t$ satisfies this equation, we'll need to find the first and second derivatives of *y* with respect to *x* and *t* and then substitute these derivatives in the wave equation.

Find the first two spatial derivatives of $y=A\sin kx\cos\omega t$:

$$\frac{\partial y}{\partial x}=Ak\cos kx\cos\omega t$$

and

$$\frac{\partial^2 y}{\partial x^2}=-Ak^2\sin kx\cos\omega t \qquad (1)$$

Find the first two temporal derivatives of $y=A\sin kx\cos\omega t$:

$$\frac{\partial y}{\partial t}=-\omega A\sin kx\sin\omega t$$

and

$$\frac{\partial^2 y}{\partial t^2}=-\omega^2 A\sin kx\cos\omega t \qquad (2)$$

Express the ratio of equation (1) to equation (2):

$$\frac{\dfrac{\partial^2 y}{\partial x^2}}{\dfrac{\partial^2 y}{\partial t^2}}=\frac{-Ak^2\sin kx\cos\omega t}{-A\omega^2\sin kx\cos\omega t}=\frac{k^2}{\omega^2}$$

$$=\boxed{\frac{1}{v^2}}$$

confirming that $y=A\sin kx\cos\omega t$ satisfies the general wave equation.

Harmonic Waves on a String

38 •

Picture the Problem We can find the velocity of the waves from the definition of velocity and their wavelength from $\lambda = v/f$.

Express the wavelength of the waves:

$$\lambda = \frac{v}{f}$$

Using the definition of velocity, find the wave velocity:

$$v = \frac{\Delta x}{\Delta t} = \frac{6\,\text{m}}{0.5\,\text{s}} = 12\,\text{m/s}$$

Substitute to obtain:

$$\lambda = \frac{12\,\text{m/s}}{60\,\text{s}^{-1}} = \boxed{20.0\,\text{cm}}$$

39 •

Picture the Problem Equation 15-13, $y(x,t) = A\sin(kx - \omega t)$, describes a wave traveling in the positive x direction. For a wave traveling in the negative x direction we have $y(x,t) = A\sin(kx + \omega t)$.

(a) Factor k from the argument of the sine function to obtain:

$$y(x,t) = A\sin k\left(x - \frac{\omega}{k}t\right) = \boxed{A\sin k(x - vt)}$$

(b) Substitute $k = 2\pi/\lambda$ and $\omega = 2\pi f$ to obtain:

$$y(x,t) = A\sin\left(\frac{2\pi}{\lambda}x - 2\pi ft\right) = \boxed{A\sin 2\pi\left(\frac{x}{\lambda} - ft\right)}$$

(c) Substitute $k = 2\pi/\lambda$ and $\omega = 2\pi/T$ to obtain:

$$y(x,t) = A\sin\left(\frac{2\pi}{\lambda} - \frac{2\pi}{T}t\right) = \boxed{A\sin 2\pi\left(\frac{x}{\lambda} - \frac{1}{T}t\right)}$$

(*d*) Substitute $k = 2\pi/\lambda$ to obtain:

$$y(x,t) = A\sin\left(\frac{2\pi}{\lambda}x - \omega t\right) = A\sin\frac{2\pi}{\lambda}\left(x - \frac{\lambda\omega}{2\pi}t\right) = \boxed{A\sin\frac{2\pi}{\lambda}(x - vt)}$$

(*e*) Substitute $k = 2\pi/\lambda$ and $\omega = 2\pi f$ to obtain:

$$y(x,t) = A\sin(kx - 2\pi ft) = A\sin 2\pi f\left(\frac{k}{2\pi f}x - t\right) = \boxed{A\sin 2\pi f\left(\frac{x}{v} - t\right)}$$

For waves traveling in the negative *x* direction, we simply change the – signs to + signs.

***40 •**

Picture the Problem We can use $f = c/\lambda$ to express the frequency of any periodic wave in terms of its wavelength and velocity.

(*a*) Find the frequency of light of wavelength 4×10^{-7} m:

$$f = \frac{c}{\lambda} = \frac{2.998\times10^{8}\ \text{m/s}}{4\times10^{-7}\ \text{m}} = 7.50\times10^{14}\ \text{Hz}$$

Find the frequency of light of wavelength 7×10^{-7} m:

$$f = \frac{c}{\lambda} = \frac{2.998\times10^{8}\ \text{m/s}}{7\times10^{-7}\ \text{m}} = 4.28\times10^{14}\ \text{Hz}$$

Therefore the range of frequencies is:

$$\boxed{4.28\times10^{14}\ \text{Hz} \le f \le 7.50\times10^{14}\ \text{Hz}}$$

(*b*) Use the same relationship to calculate the frequency of these microwaves:

$$f = \frac{c}{\lambda} = \frac{2.998\times10^{8}\ \text{m/s}}{3\times10^{-2}\ \text{m}} = \boxed{1.00\times10^{10}\ \text{Hz}}$$

41 •

Picture the Problem The average power propagated along the string by a harmonic wave is $P_{av} = \frac{1}{2}\mu\omega^2A^2v$, where *v* is the speed of the wave, and μ, ω, and *A* are the linear density of the string, the angular frequency of the wave, and the amplitude of the wave, respectively.

Express and evaluate the power propagated along the string:

$$P_{av} = \tfrac{1}{2}\mu\omega^2 A^2 v$$

The speed of the wave on the string is given by:

$$v = \sqrt{\frac{F}{\mu}}$$

Substitute for v to obtain:

$$P_{av} = \tfrac{1}{2}\mu\omega^2 A^2 \sqrt{\frac{F}{\mu}}$$

Substitute numerical values and evaluate P_{av}:

$$P_{av} = \tfrac{1}{2}\left(4\pi^2\right)(0.05\,\text{kg/m})\left(10\,\text{s}^{-1}\right)^2(0.05\,\text{m})^2\sqrt{\frac{80\,\text{N}}{0.05\,\text{kg/m}}} = \boxed{9.87\,\text{W}}$$

42 •

Picture the Problem The average power propagated along the rope by a harmonic wave is $P_{av} = \tfrac{1}{2}\mu\omega^2 A^2 v$, where v is the velocity of the wave, and μ, ω, and A are the linear density of the string, the angular frequency of the wave, and the amplitude of the wave, respectively.

Rewrite the power equation in terms of the frequency of the wave:

$$P_{av} = \tfrac{1}{2}\mu\omega^2 A^2 v = 2\pi^2 \mu f^2 A^2 v$$

Solve for the frequency:

$$f = \sqrt{\frac{P_{av}}{2\pi^2 \mu A^2 v}} = \frac{1}{2\pi A}\sqrt{\frac{2P_{av}}{\mu v}}$$

The wave velocity is given by:

$$v = \sqrt{\frac{F}{\mu}}$$

Substitute for v and simplify to obtain:

$$f = \frac{1}{2\pi A}\sqrt{\frac{2P_{av}}{\mu\sqrt{\frac{F}{\mu}}}} = \frac{1}{2\pi A}\sqrt{\frac{2P_{av}}{\sqrt{\mu F}}}$$

Substitute numerical values and evaluate f:

$$f = \frac{1}{2\pi(0.01\,\text{m})}\sqrt{\frac{2(100\,\text{W})}{\sqrt{\left(\frac{0.1\,\text{kg}}{2\,\text{m}}\right)(60\,\text{N})}}} = \boxed{171\,\text{Hz}}$$

43 ••

Picture the Problem Equation 15-13, $y(x,t) = A\sin(kx - \omega t)$, describes a wave traveling in the positive *x* direction. For a wave traveling in the negative *x* direction, we have $y(x,t) = A\sin(kx + \omega t)$. We can determine *A, k,* and ω by examination of the wave function. The wavelength, frequency, and period of the wave can, in turn, be determined from *k* and ω.

(*a*) Because the sign between the *kx* and ωt terms is positive, the wave is traveling in the negative *x* direction.

Find the speed of the wave:

$$v = \frac{\omega}{k} = \frac{314\,\text{s}^{-1}}{62.8\,\text{m}^{-1}} = \boxed{5.00\,\text{m/s}}$$

(*b*) The coefficient of *x* is *k* and:

$$k = \frac{2\pi}{\lambda}$$

Solve for and evaluate λ:

$$\lambda = \frac{2\pi}{k} = \frac{2\pi}{62.8\,\text{m}^{-1}} = \boxed{10.0\,\text{cm}}$$

The coefficient of *t* is ω and:

$$f = \frac{\omega}{2\pi} = \frac{314\,\text{s}^{-1}}{2\pi} = \boxed{50.0\,\text{Hz}}$$

The period of the wave motion is the reciprocal of its frequency:

$$T = \frac{1}{f} = \frac{1}{50\,\text{s}^{-1}} = \boxed{0.0200\,\text{s}}$$

(*c*) Express and evaluate the maximum speed of any string segment:

$$v_{max} = A\omega = (0.001\,\text{m})(314\,\text{rad/s}) = \boxed{0.314\,\text{m/s}}$$

44 ••

Picture the Problem Let the positive *x* direction be to the right. Then equation 15-13, $y(x,t) = A\sin(kx - \omega t)$, describes a wave traveling in the positive *x* direction. We can find ω and *k* from the data included in the problem statement and substitute in the general equation. The maximum speed of a point on the string can be found from $v_{max} = A\omega$ and the maximum acceleration from $a_{max} = A\omega^2$.

(*a*) Express the general form of the equation of a harmonic wave traveling to the right:

$$y(x,t) = A\sin(kx - \omega t)$$

Evaluate ω:

$$\omega = 2\pi f = 2\pi\left(80\,\text{s}^{-1}\right) = 503\,\text{s}^{-1}$$

Determine k:

$$k = \frac{\omega}{v} = \frac{503\,\text{s}^{-1}}{12\,\text{m/s}} = 41.9\,\text{m}^{-1}$$

Substitute to obtain: $y(x,t) = \boxed{(0.025\,\text{m})\sin\left[\left(41.9\,\text{m}^{-1}\right)x - \left(503\,\text{s}^{-1}\right)t\right]}$

(*b*) Express and evaluate the maximum speed of a point on the string:

$$v_{\text{max}} = A\omega = (0.025\,\text{m})\left(503\,\text{s}^{-1}\right) = \boxed{12.6\,\text{m/s}}$$

(*c*) Express the maximum acceleration of a point on the string:

$$a_{\text{max}} = A\omega^2$$

Substitute numerical values and evaluate a_{max}:

$$a_{\text{max}} = (0.025\,\text{m})\left(503\,\text{s}^{-1}\right)^2 = \boxed{6.33\,\text{km/s}^2}$$

45 ••

Picture the Problem The average total energy of waves on a string is given by $\Delta E_{\text{av}} = \frac{1}{2}\mu\omega^2A^2\Delta x,$ where μ is the linear density of the string, ω is its angular frequency, A the amplitude of the wave motion, and, in this problem, Δx is the length of the string. The average power propagated along the string is $P_{\text{av}} = \frac{1}{2}\mu\omega^2A^2v.$

(*a*) ΔE_{av} is given by:

$$\Delta E_{\text{av}} = \tfrac{1}{2}\mu\omega^2A^2\Delta x = 2\pi^2\mu f^2A^2\Delta x$$

Evaluate $\Delta E_{\text{av}} = \frac{1}{2}\mu\omega^2A^2\Delta x$ with $\Delta x = L = 20$ m:

$$\Delta E_{\text{av}} = 2\pi^2\left(\frac{0.06\,\text{kg}}{20\,\text{m}}\right)\left(200\,\text{s}^{-1}\right)^2(0.012\,\text{m})^2(20\,\text{m}) = \boxed{6.82\,\text{J}}$$

(*b*) Express the power transmitted past a given point on the string:

$$P_{\text{av}} = \tfrac{1}{2}\mu\omega^2A^2v$$

The speed of the wave is given by: $v = \sqrt{\frac{F}{\mu}}$

Substitute for v to obtain: $P_{av} = \frac{1}{2}\mu\omega^2 A^2 \sqrt{\frac{F}{\mu}}$

Substitute numerical values and evaluate P_{av}:

$$P_{av} = 2\pi^2\left(\frac{0.06\,\text{kg}}{20\,\text{m}}\right)\left(200\,\text{s}^{-1}\right)^2(0.012\,\text{m})^2\sqrt{\frac{50\,\text{N}}{\frac{0.06\,\text{kg}}{20\,\text{m}}}} = \boxed{44.0\,\text{W}}$$

***46 ••**

Picture the Problem The power propagated along the rope by a harmonic wave is $P = \frac{1}{2}\mu\omega^2 A^2 v$ where v is the velocity of the wave, and μ, ω, and A are the linear density of the string, the angular frequency of the wave, and the amplitude of the wave, respectively. We can use the wave function $y = \left(A_0 e^{-bx}\right)\sin(kx - \omega t)$ to determine the amplitude of the wave at $x = 0$ and at point x.

(*a*) Express the power associated with the wave at the origin: $P = \frac{1}{2}\mu\omega^2 A^2 v$

Evaluate the amplitude at $x = 0$: $A(0) = \left(A_0 e^0\right) = A_0$

Substitute to obtain: $P(0) = \boxed{\frac{1}{2}\mu\omega^2 A_0^2 v}$

(*b*) Express the amplitude of the wave at x: $A(x) = \left(A_0 e^{-bx}\right)$

Substitute to obtain:

$$P(x) = \frac{1}{2}\mu\omega^2\left(A_0 e^{-bx}\right)^2 v = \boxed{\frac{1}{2}\mu\omega^2 A_0^2 v e^{-2bx}}$$

47 ••

Picture the Problem The average power propagated along the rope by a harmonic wave is $P_{av} = \frac{1}{2}\mu\omega^2 A^2 v$ where v is the velocity of the wave, and μ, ω, and A are the linear density of the string, the angular frequency of the wave, and the amplitude of the wave, respectively.

(*a*) Express the average power transmitted along the wire:

$$P_{av} = \tfrac{1}{2}\mu\omega^2 A^2 v = 2\pi^2 \mu f^2 A^2 v$$

Substitute numerical values and evaluate P_{av}:

$$P_{av} = 2\pi^2(0.01\,\text{kg/m})(400\,\text{s}^{-1})^2 \times (0.5\times10^{-3}\,\text{m})^2(10\,\text{m/s}) = \boxed{79.0\,\text{mW}}$$

(*b*) Because $P_{av} \propto f^2$:

Increasing f by a factor of 10 would increase P_{av} by a factor of 100.

Because $P_{av} \propto A^2$:

Increasing A by a factor of 10 would increase P_{av} by a factor of 100.

Because $P_{av} \propto v$ and $v \propto \sqrt{F}$:

Increasing F by a factor of 10^4 would increase v by a factor of 100 and P_{av} by a factor of 100.

(*c*)

Depending on the adjustability of the power source, increasing f or A would be the easiest.

***48 •••**

Picture the Problem We can use the assumption that both the wave function and its first spatial derivative are continuous at $x = 0$ to establish equations relating A, B, C, k_1, and k_2. Then, we can solve these simultaneous equations to obtain expressions for B and C in terms of A, v_1, and v_2.

(*a*) Let $y_1(x, t)$ represent the wave function in the region $x < 0$, and $y_2(x, t)$ represent the wave function in the region $x > 0$. Express the continuity of the two wave functions at $x = 0$:

$$y_1(0,t) = y_2(0,t)$$

and

$$A\sin[k_1(0) - \omega t] + B\sin[k_1(0) + \omega t] = C\sin[k_2(0) - \omega t]$$

or

$$A\sin(-\omega t) + B\sin\omega t = C\sin(-\omega t)$$

Because the sine function is odd; i.e., $\sin(-\theta) = -\sin\theta$:

$$-A\sin\omega t + B\sin\omega t = -C\sin\omega t$$

and

$$A - B = C \qquad (1)$$

Differentiate the wave functions with respect to x to obtain:

$$\frac{\partial y_1}{\partial x} = Ak_1 \cos(k_1 x - \omega t) + Bk_1 \cos(k_1 x + \omega t)$$

and

$$\frac{\partial y_2}{\partial x} = Ck_2 \cos(k_2 x - \omega t)$$

Express the continuity of the slopes of the two wave functions at $x = 0$:

$$\left.\frac{\partial y_1}{\partial x}\right|_{x=0} = \left.\frac{\partial y_2}{\partial x}\right|_{x=0}$$

and

$$Ak_1 \cos[k_1(0) - \omega t] + Bk_1 \cos[k_1(0) + \omega t] = Ck_2 \cos[k_2(0) - \omega t]$$

or

$$Ak_1 \cos(-\omega t) + Bk_1 \cos \omega t = Ck_2 \cos(-\omega t)$$

Because the cosine function is even; i.e., $\cos(-\theta) = \cos\theta$:

$$Ak_1 \cos \omega t + Bk_1 \cos \omega t = Ck_2 \cos \omega t$$

and

$$k_1 A + k_1 B = k_2 C \qquad (2)$$

Multiply equation (1) by k_1 and add it to equation (2) to obtain:

$$2k_1 A = (k_1 + k_2)C$$

Solve for C:

$$C = \frac{2k_1}{k_1 + k_2} A = \frac{2}{1 + k_2/k_1} A$$

Solve for C/A and substitute ω/v_1 for k_1 and ω/v_2 for k_2 to obtain:

$$\frac{C}{A} = \frac{2}{1 + k_2/k_1} = \boxed{\frac{2}{1 + v_1/v_2}}$$

Substitute in equation (1) to obtain:

$$A - B = \left(\frac{2}{1 + v_1/v_2}\right) A$$

Solve for B/A:

$$\frac{B}{A} = \boxed{-\frac{1 - v_1/v_2}{1 + v_1/v_2}}$$

(b) We wish to show that

$$B^2 + (v_1/v_2)C^2 = A^2$$

Use the results of (a) to obtain the expressions $B = -[(1 - \alpha)/(1 + \alpha)]\,A$ and $C = 2A/(1 + \alpha)$, where $\alpha = v_1/v_2$.

Substitute these expressions into

$$B^2 + (v_1/v_2)C^2 = A^2$$

and check to see if the resulting equation is an identity:

$$B^2 + \frac{v_1}{v_2}C^2 = A^2$$

$$\left(\frac{1-\alpha}{1+\alpha}\right)^2 A^2 + \alpha\left(\frac{2}{1+\alpha}\right)^2 A^2 = A^2$$

$$\left(\frac{1-\alpha}{1+\alpha}\right)^2 + \alpha\left(\frac{2}{1+\alpha}\right)^2 = 1$$

$$\frac{(1-\alpha)^2 + 4\alpha}{(1+\alpha)^2} = 1$$

$$\frac{1 - 2\alpha + \alpha^2 + 4\alpha}{(1+\alpha)^2} = 1$$

$$\frac{1 + 2\alpha + \alpha^2}{(1+\alpha)^2} = 1$$

$$\frac{(1+\alpha)^2}{(1+\alpha)^2} = 1$$

$$1 = 1$$

The equation is an identity:

Therefore, $\boxed{B^2 + \frac{v_1}{v_2}C^2 = A^2}$

Remarks: Our result in (*a*) can be checked by considering the limit of *B*/*A* as $v_2/v_1 \to 0$. This limit gives *B*/*A* = +1, telling us that the transmitted wave has zero amplitude and the incident and reflected waves superpose to give a standing wave with a node at *x* = 0.

Harmonic Sound Waves

***49** •

Picture the Problem The pressure variation is of the form $p(x,t) = p_0 \cos k(x - vt)$ where $k = \frac{\pi}{2}$ and $v = 340\,\text{m/s}$. We can find λ from k and f from ω and k.

(a) By inspection of the equation:

$$p_0 = \boxed{0.750\,\text{Pa}}$$

(b) Because $k = \frac{2\pi}{\lambda} = \frac{\pi}{2}$:

$$\lambda = \boxed{4.00\,\text{m}}$$

(c) Solve $v = \frac{\omega}{k} = \frac{2\pi f}{k}$ for f to obtain:

$$f = \frac{kv}{2\pi} = \frac{\frac{\pi}{2}(340\,\text{m/s})}{2\pi} = \boxed{85.0\,\text{Hz}}$$

(*d*) By inspection of the equation: $v = \boxed{340\,\text{m/s}}$

50 •

Picture the Problem The frequency, wavelength, and speed of the sound waves are related by $v = f\lambda$.

(*a*) Express and evaluate the wavelength of middle C:

$$\lambda = \frac{v}{f} = \frac{340\,\text{m/s}}{262\,\text{s}^{-1}} = \boxed{1.30\,\text{m}}$$

(*b*) Double the frequency corresponding to middle C; solve for and evaluate λ:

$$\lambda = \frac{v}{f} = \frac{340\,\text{m/s}}{2\left(262\,\text{s}^{-1}\right)} = \boxed{0.649\,\text{m}}$$

51 •

Picture the Problem The pressure amplitude depends on the density of the medium ρ, the angular frequency of the sound wave μ, the speed of the wave v, and the displacement amplitude s_0 according to $p_0 = \rho\omega v s_0$.

(*a*) Solve $p_0 = \rho\omega v s_0$ for s_0:

$$s_0 = \frac{p_0}{\rho\omega v}$$

Substitute numerical values and evaluate s_0:

$$s_0 = \frac{\left(10^{-4}\,\text{atm}\right)\left(1.01325\times10^{5}\,\text{Pa/atm}\right)}{2\pi\left(1.29\,\text{kg/m}^3\right)\left(100\,\text{s}^{-1}\right)\left(340\,\text{m/s}\right)} = \boxed{3.68\times10^{-5}\,\text{m}}$$

(*b*) Use $p_0 = \rho\omega v s_0$ to find p_0:

$$p_0 = 2\pi\left(1.29\,\text{kg/m}^3\right)\left(300\,\text{s}^{-1}\right)\left(340\,\text{m/s}\right)\left(10^{-7}\,\text{m}\right) = \boxed{8.27\times10^{-2}\,\text{Pa}}$$

52 •

Picture the Problem The pressure amplitude depends on the density of the medium ρ, the angular frequency of the sound wave μ, the speed of the wave v, and the displacement amplitude s_0 according to $p_0 = \rho\omega v s_0$.

(*a*) Solve $p_0 = \rho\omega v s_0$ for s_0:

$$s_0 = \frac{p_0}{\rho\omega v}$$

Substitute numerical values and evaluate s_0:

$$s_0 = \frac{29\,\text{Pa}}{2\pi(1.29\,\text{kg/m}^3)(1000\,\text{s}^{-1})(340\,\text{m/s})} = \boxed{2.10\times10^{-5}\,\text{m}}$$

(*b*) Proceed as in (*a*) with $f = 1$ kHz:

$$s_0 = \frac{29\,\text{Pa}}{2\pi(1.29\,\text{kg/m}^3)(1000\,\text{s}^{-1})(340\,\text{m/s})} = \boxed{1.05\times10^{-5}\,\text{m}}$$

53 •

Picture the Problem The pressure or density wave is 90° out of phase with the displacement wave. When the displacement is zero, the pressure and density changes are either a maximum or a minimum. When the displacement is a maximum or minimum, the pressure and density changes are zero. We can use $p_0 = \rho\omega v s_0$ to find the maximum value of the displacement at any time and place.

(*a*) If the pressure is a maximum at x_1 when $t = 0$:

$\boxed{\text{the displacement } s \text{ is zero.}}$

(*b*) Solve $p_0 = \rho\omega v s_0$ for s_0:

$$s_0 = \frac{p_0}{\rho\omega v}$$

Substitute numerical values and evaluate s_0:

$$s_0 = \frac{(10^{-4}\,\text{atm})(1.01325\times10^5\,\text{Pa/atm})}{2\pi(1.29\,\text{kg/m}^3)(1000\,\text{s}^{-1})(340\,\text{m/s})} = \boxed{3.68\,\mu\text{m}}$$

***54** •

Picture the Problem A human can hear sounds between roughly 20 Hz and 20 kHz; a factor of 1000. An octave represents a change in frequency by a factor of 2. We can evaluate $2^N = 1000$ to find the number of octaves heard by a person who can hear this range of frequencies.

Relate the number of octaves to the difference between 20 kHz and 20 Hz:

$$2^N = 1000$$

Take the logarithm of both sides of the equation to obtain:

$$\log 2^N = \log 10^3$$

or

$$N \log 2 = 3$$

Solve for and evaluate N:

$$N = \frac{3}{\log 2} = 9.97 \approx \boxed{10}$$

Waves in Three Dimensions: Intensity

55 •

Picture the Problem The pressure amplitude depends on the density of the medium ρ, the angular frequency of the sound wave μ, the speed of the wave v, and the displacement amplitude s_0 according to $p_0 = \rho\omega v s_0$. The intensity of the waves is given by $I = \frac{1}{2}\rho\omega^2 s_0^2 v = \frac{1}{2}\frac{p_0^2}{\rho v}$ and the rate at which energy is delivered (power) is the product of the intensity and the surface area of the piston.

(*a*) Using $p_0 = \rho\omega v s_0$, evaluate p_0:

$$p_0 = 2\pi\left(1.29\,\text{kg/m}^3\right)\left(500\,\text{s}^{-1}\right)\times\left(340\,\text{m/s}\right)\left(0.1\times10^{-3}\,\text{m}\right) = \boxed{138\,\text{Pa}}$$

(*b*) Use $I = \frac{1}{2}\frac{p_0^2}{\rho v}$ to find the intensity of the waves:

$$I = \frac{1}{2}\frac{(138\,\text{Pa})^2}{\left(1.29\,\text{kg/m}^3\right)(340\,\text{m/s})} = \boxed{21.7\,\text{W/m}^2}$$

(*c*) Using $P_{\text{av}} = IA$ to find the power required to keep the piston oscillating:

$$P_{\text{av}} = \left(21.6\,\text{W/m}^2\right)\left(10^{-2}\,\text{m}^2\right) = \boxed{0.217\,\text{W}}$$

56 •

Picture the Problem The intensity of the sound from the spherical source varies inversely with the square of the distance from the source. The power radiated by the source is the product of the intensity of the radiation and the surface area over which it is distributed.

(*a*) Relate the intensity at 10 m to the distance from the source:

$$I = \frac{P_{\text{av}}}{4\pi r^2}$$

or

$$10^{-4}\,\text{W/m}^2 = \frac{P_{\text{av}}}{4\pi(10\,\text{m})^2}$$

Letting r' represent the distance at which the intensity is 10^{-6} W/m^2, express the intensity as in part (*a*):

$$10^{-6}\,\text{W/m}^2 = \frac{P_{\text{av}}}{4\pi r'^2}$$

Divide the first of these equations by the second to obtain:

$$\frac{10^{-4}\ \text{W/m}^2}{10^{-6}\ \text{W/m}^2}=\frac{\dfrac{P_{\text{av}}}{4\pi(10\,\text{m})^2}}{\dfrac{P_{\text{av}}}{4\pi r'^2}}$$

Solve for and evaluate r':

$$r'=\sqrt{(10^2)(10\,\text{m})^2}=\boxed{100\,\text{m}}$$

(b) Solve $I=\dfrac{P_{\text{av}}}{4\pi r^2}$ for P_{av}:

$$P_{\text{av}}=4\pi r^2 I$$

Substitute numerical values and evaluate P_{av}:

$$P_{\text{av}}=4\pi(10\,\text{m})^2\left(10^{-4}\ \text{W/m}^2\right)=\boxed{0.126\,\text{W}}$$

***57 •**

Picture the Problem Because the power radiated by the loudspeaker is the product of the intensity of the sound and the surface area over which it is distributed, we can use this relationship to find the average power, the intensity of the radiation, or the distance to the speaker for a given intensity or average power.

(a) Use $P_{\text{av}}=4\pi r^2 I$ to find the total acoustic power output of the speaker:

$$P_{\text{av}}=4\pi(20\,\text{m})^2\left(10^{-2}\ \text{W/m}^2\right)=\boxed{50.3\,\text{W}}$$

(b) Relate the intensity of the sound at 20 m to the distance from the speaker:

$$10^{-2}\ \text{W/m}^2=\frac{P_{\text{av}}}{4\pi(20\,\text{m})^2}$$

Relate the threshold-of-pain intensity to the distance from the speaker:

$$1\,\text{W/m}^2=\frac{P_{\text{av}}}{4\pi r^2}$$

Divide the first of these equations by the second; solve for and evaluate r:

$$r=\sqrt{10^{-2}(20\,\text{m})^2}=\boxed{2.00\,\text{m}}$$

(c) Use $I=\dfrac{P_{\text{av}}}{4\pi r^2}$ to find the intensity at 30 m:

$$I(30\,\text{m})=\frac{50.3\,\text{W}}{4\pi(30\,\text{m})^2}=\boxed{4.45\times10^{-3}\ \text{W/m}^2}$$

58 ••

Picture the Problem We can use conservation of energy to find the acoustical energy resulting from the dropping of the pin. The power developed can then be found from the given time during which the energy was transformed from mechanical to acoustical form. We can find the range at which the dropped pin can be heard from $I = P/4\pi r^2$.

(*a*) Assuming that $I = P/4\pi r^2$, express the distance at which one can hear the dropped pin:

$$r = \sqrt{\frac{P}{4\pi I}}$$

Use conservation of energy to determine the sound energy generated when the pin falls:

$$E = (0.0005)(mgh) = (0.0005)(0.1\times10^{-3}\text{ kg})(9.81\text{ m/s}^2)\times(1\text{ m}) = 4.91\times10^{-7}\text{ J}$$

Express the power of the sound pulse:

$$P = \frac{E}{\Delta t} = \frac{4.91\times10^{-7}\text{ J}}{0.1\text{ s}} = 4.91\times10^{-6}\text{ W}$$

Substitute numerical values and evaluate *r*:

$$r = \sqrt{\frac{4.91\times10^{-6}\text{ W}}{4\pi(10^{-11}\text{ W/m}^2)}} = \boxed{198\text{ m}}$$

(*b*) Repeat the last step in (*a*) with $I = 10^{-8}$ W/m^2:

$$r = \sqrt{\frac{4.91\times10^{-6}\text{ W}}{4\pi(10^{-8}\text{ W/m}^2)}} = \boxed{6.25\text{ m}}$$

Intensity Level

59 •

Picture the Problem The intensity level of a sound wave β, measured in decibels, is given by $\beta = (10\text{ dB})\log(I/I_0)$ where $I_0 = 10^{-12}$ W/m^2 is defined to be the threshold of hearing.

(*a*) Using its definition, calculate the intensity level of a sound wave whose intensity is 10^{-10} W/m^2:

$$\beta = (10\text{ dB})\log\left(\frac{10^{-10}\text{ W/m}^2}{10^{-12}\text{ W/m}^2}\right) = 10\log10^2 = \boxed{20.0\text{ dB}}$$

(*b*) Proceed as in (*a*) with $I = 10^{-2}$ W/m^2:

$$\beta = (10\,\text{dB})\log\left(\frac{10^{-2}\ \text{W/m}^2}{10^{-12}\ \text{W/m}^2}\right)$$
$$= 10\log 10^{10} = \boxed{100\,\text{dB}}$$

60 •

Picture the Problem The intensity level of a sound wave β, measured in decibels, is given by $\beta = (10\,\text{dB})\log(I/I_0)$ where $I_0 = 10^{-12}$ W/m^2 is defined to be the threshold of hearing.

(*a*) Solve $\beta = (10\,\text{dB})\log(I/I_0)$ for I to obtain:

$$I = 10^{\beta/(10\,\text{dB})}I_0$$

Evaluate I for β = 10 dB:

$$I = 10^{(10\,\text{dB})/(10\,\text{dB})}I_0 = 10I_0$$
$$= 10\left(10^{-12}\ \text{W/m}^2\right) = \boxed{10^{-11}\ \text{W/m}^2}$$

(*b*) Proceed as in (*a*) with β = 3 dB:

$$I = 10^{(3\,\text{dB})/(10\,\text{dB})}I_0 = 2I_0$$
$$= 2\left(10^{-12}\ \text{W/m}^2\right) = \boxed{2\times10^{-12}\ \text{W/m}^2}$$

***61** •

Picture the Problem The intensity level of a sound wave β, measured in decibels, is given by $\beta = (10\,\text{dB})\log(I/I_0)$ where $I_0 = 10^{-12}$ W/m^2 is defined to be the threshold of hearing.

Express the sound level of the rock concert:

$$\beta_{\text{concert}} = (10\,\text{dB})\log\left(\frac{I_{\text{concert}}}{I_0}\right) \qquad (1)$$

Express the sound level of the dog's bark:

$$50\,\text{dB} = (10\,\text{dB})\log\left(\frac{I_{\text{dog}}}{I_0}\right)$$

Solve for the intensity of the dog's bark:

$$I_{\text{dog}} = 10^5 I_0 = 10^5\left(10^{-12}\ \text{W/m}^2\right)$$
$$= 10^{-7}\ \text{W/m}^2$$

Express the intensity of the rock concert in terms of the intensity of the dog's bark:

$$I_{\text{concert}} = 10^4 I_{\text{dog}} = 10^4\left(10^{-7}\ \text{W/m}^2\right)$$
$$= 10^{-3}\ \text{W/m}^2$$

Substitute in equation (1) and evaluate β_{concert}:

$$\beta_{\text{concert}} = (10\,\text{dB})\log\left(\frac{10^{-3}\ \text{W/m}^2}{10^{-12}\ \text{W/m}^2}\right) = (10\,\text{dB})\log 10^9 = \boxed{90.0\,\text{dB}}$$

62 •

Picture the Problem The intensity level of a sound wave β, measured in decibels, is given by $\beta = (10\,\text{dB})\log(I/I_0)$ where $I_0 = 10^{-12}$ W/m^2 is defined to be the threshold of hearing.

Express the intensity level of the louder sound:

$$\beta_{\text{L}} = (10\,\text{dB})\log\left(\frac{I_{\text{L}}}{I_0}\right)$$

Express the intensity level of the softer sound:

$$\beta_{\text{S}} = (10\,\text{dB})\log\left(\frac{I_{\text{S}}}{I_0}\right)$$

Express the difference between the intensity levels of the two sounds:

$$\beta_{\text{L}} - \beta_{\text{S}} = 30\,\text{dB} = (10\,\text{dB})\left[\log\left(\frac{I_{\text{L}}}{I_0}\right) - \log\left(\frac{I_{\text{S}}}{I_0}\right)\right] = (10\,\text{dB})\log\left(\frac{I_{\text{L}}/I_0}{I_{\text{S}}/I_0}\right) = (10\,\text{dB})\log\left(\frac{I_{\text{L}}}{I_{\text{S}}}\right)$$

Solve for and evaluate the ratio $I_{\text{L}}/I_{\text{S}}$:

$$\frac{I_{\text{L}}}{I_{\text{S}}} = 10^3 \text{ and } \boxed{(a)\text{ is correct.}}$$

63 •

Picture the Problem We can use the definition of the intensity level to express the difference in the intensity levels of two sounds whose intensities differ by a factor of 2.

Express the intensity level before the intensity is doubled:

$$\beta_1 = (10\,\text{dB})\log\left(\frac{I}{I_0}\right)$$

Express the intensity level with the intensity doubled:

$$\beta_2 = (10\,\text{dB})\log\left(\frac{2I}{I_0}\right)$$

Express and evaluate $\Delta\beta = \beta_2 - \beta_1$:

$$\begin{aligned}\Delta\beta &= \beta_2 - \beta_1 \\ &= (10\,\text{dB})\log\left(\frac{2I}{I_0}\right) - (10\,\text{dB})\log\left(\frac{I}{I_0}\right) \\ &= (10\,\text{dB})\log\left(\frac{2I}{I}\right) = (10\,\text{dB})\log 2 \\ &= 3.01\,\text{dB} \approx \boxed{3.0\,\text{dB}}\end{aligned}$$

***64 •**

Picture the Problem We can express the intensity levels at both 90 dB and 70 dB in terms of the intensities of the sound at those levels. By subtracting the two expressions, we can solve for the ratio of the intensities at the two levels and then find the fractional change in the intensity that corresponds to a decrease in intensity level from 90 dB to 70 dB.

Express the intensity level at 90 dB:

$$90\,\text{dB} = (10\,\text{dB})\log\left(\frac{I_{90}}{I_0}\right)$$

Express the intensity level at 70 dB:

$$70\,\text{dB} = (10\,\text{dB})\log\left(\frac{I_{70}}{I_0}\right)$$

Express $\Delta\beta = \beta_{90} - \beta_{70}$:

$$\begin{aligned}\Delta\beta &= 20\,\text{dB} \\ &= (10\,\text{dB})\log\left(\frac{I_{90}}{I_0}\right) - (10\,\text{dB})\log\left(\frac{I_{70}}{I_0}\right) \\ &= (10\,\text{dB})\log\left(\frac{I_{90}}{I_{70}}\right)\end{aligned}$$

Solve for I_{90}:

$$I_{90} = 100 I_{70}$$

Express the fractional change in the intensity from 90 dB to 70 dB:

$$\frac{I_{90} - I_{70}}{I_{90}} = \frac{100 I_{70} - I_{70}}{100 I_{70}} = \boxed{99\%}$$

65 ••

Picture the Problem The intensity at a distance r from a spherical source varies with distance from the source according to $I = P_{\text{av}}/4\pi r^2$. We can use this relationship to relate the intensities corresponding to an 80-dB intensity level (I_{80}) and the intensity corresponding to a 60-dB intensity level (I_{60}) to their distances from the source. We can relate the intensities to the intensity levels through $\beta = (10\,\text{dB})\log(I/I_0)$.

(*a*) Express the intensity of the sound where the intensity level is 80 dB:

$$I_{10} = \frac{P_{av}}{4\pi r_{10}^2}$$

Express the intensity of the sound where the intensity level is 60 dB:

$$I_{60} = \frac{P_{av}}{4\pi r^2}$$

Divide the first of these equations by the second to obtain:

$$\frac{I_{80}}{I_{60}} = \frac{\frac{P_{av}}{4\pi(10\,\text{m})^2}}{\frac{P_{av}}{4\pi r^2}} = \frac{r^2}{100\,\text{m}^2}$$

Solve for *r*:

$$r = (10\,\text{m})\sqrt{\frac{I_{80}}{I_{60}}}$$

Find the intensity of the 80-dB sound level radiation:

$$80\,\text{dB} = (10\,\text{dB})\log\left(\frac{I_{80}}{I_0}\right)$$

and

$$I_{80} = 10^8 I_0 = 10^{-4}\ \text{W/m}^2$$

Find the intensity of the 60-dB sound level radiation:

$$60\,\text{dB} = (10\,\text{dB})\log\left(\frac{I_{60}}{I_0}\right)$$

and

$$I_{60} = 10^6 I_0 = 10^{-6}\ \text{W/m}^2$$

Substitute and evaluate *r*:

$$r = (10\,\text{m})\sqrt{\frac{10^{-4}\ \text{W/m}^2}{10^{-6}\ \text{W/m}^2}} = \boxed{100\,\text{m}}$$

(*b*) Using the intensity corresponding to an intensity level of 80 dB, express and evaluate the power radiated by this source:

$$P = I_{80}A = (10^{-4}\ \text{W/m}^2)\left[4\pi(10\,\text{m})^2\right] = \boxed{0.126\,\text{W}}$$

66 ••

Picture the Problem Let I_1 and I_2 be the intensities of the sound at distances r_1 and r_2. We can relate these intensities to the intensity levels through $\beta = (10\,\text{dB})\log(I/I_0)$ and to the distances through $I = P_{av}/4\pi r^2$.

Using $\beta = (10\,\text{dB})\log(I/I_0)$, express the ratio β_1/β_2:

$$\frac{\beta_2}{\beta_1} = \frac{(10\,\text{dB})\log(I_2/I_0)}{(10\,\text{dB})\log(I_1/I_0)} = \frac{\log I_2 - \log I_0}{\log I_1 - \log I_0}$$

Express the ratio of the intensities at distances r_1 and r_2 from the source and solve for I_2:

$$\frac{I_2}{I_1} = \frac{r_1^2}{r_2^2} \text{ and } I_2 = \frac{r_1^2}{r_2^2} I_1$$

Substitute and simplify to obtain:

$$\frac{\beta_2}{\beta_1} = \frac{10\log\frac{r_1^2}{r_2^2} I_1 - 10\log I_0}{\log I_1 - \log I_0} = \frac{10\log I_1 + 20\log(r_1/r_2) - 10\log I_0}{10\log I_1 - 10\log I_0}$$

$$= \frac{10\log(I_1/I_0) + 20\log(r_1/r_2)}{10\log(I_1/I_0)} = \boxed{\frac{\beta_1 + 20\log(r_1/r_2)}{\beta_1}}$$

67 ••

Picture the Problem We can use $\beta = (10\,\text{dB})\log(I/I_0)$ where $I_0 = 10^{-12}$ W/m^2 is defined to be the threshold of hearing, to find the intensity level at 20 m. Because the power radiated by the loudspeaker is the product of the intensity of the sound and the surface area over which it is distributed, we can use this relationship to find either the average power, the intensity of the radiation, or the distance to the speaker for a given intensity or average power.

(*a*) Relate the intensity level to the intensity at 20 m:

$$\beta = (10\,\text{dB})\log\left(\frac{I}{I_0}\right) = (10\,\text{dB})\log\left(\frac{10^{-2}\ \text{W/m}^2}{10^{-12}\ \text{W/m}^2}\right) = (10\,\text{dB})\log(10^{10}) = \boxed{100\,\text{dB}}$$

(*b*) Use $P_{\text{av}} = 4\pi r^2 I$ to find the total acoustic power output of the speaker:

$$P_{\text{av}} = 4\pi(20\,\text{m})^2(10^{-2}\ \text{W/m}^2) = \boxed{50.3\,\text{W}}$$

(*c*) Relate the intensity of the sound at 20 m to the distance from the speaker:

$$10^{-2}\ \text{W/m}^2 = \frac{P_{\text{av}}}{4\pi(20\,\text{m})^2}$$

Relate the threshold-of-pain intensity to the distance from the speaker:

$$1\,\text{W/m}^2 = \frac{P_{\text{av}}}{4\pi r^2}$$

Divide the first of these equations by the second; solve for and evaluate r:

$$r = \sqrt{10^{-2}(20\,\text{m})^2} = \boxed{2.00\,\text{m}}$$

(*d*) Use $I = \dfrac{P_{\text{av}}}{4\pi r^2}$ to find the intensity at 30 m:

$$I(30\,\text{m}) = \frac{50.3\,\text{W}}{4\pi(30\,\text{m})^2} = 4.45\times10^{-3}\ \text{W/m}^2$$

Find the intensity level at 30 m:

$$\beta(30\,\text{m}) = (10\,\text{dB})\log\frac{4.45\times10^{-3}\ \text{W/m}^2}{10^{-12}\ \text{W/m}^2} = (10\,\text{dB})\log 4.45\times10^{9} = \boxed{96.5\,\text{dB}}$$

68 ••

Picture the Problem Let *I′* and *I* represent the sound in consecutive years. Then, we can use $\beta = (10\,\text{dB})\log(I/I_0)$ to express the annual increase in intensity levels.

(*a*) Express the annual change in intensity level:

$$\Delta\beta = \beta' - \beta = 1\,\text{dB} = (10\,\text{dB})\log\frac{I'}{I_0} - (10\,\text{dB})\log\frac{I}{I_0} = (10\,\text{dB})\log\frac{I'}{I}$$

Solve for *I′*/*I*:

$$\frac{I'}{I} = 10^{0.1} = 1.26$$

and the annual increase in intensity is $\boxed{26\%.}$ This is not a plausible annual increase because, if it were true, the intensity level would increase by a factor of 10 in ten years.

(*b*) Because doubling of the intensity corresponds to $\Delta\beta$ = 3 dB and the intensity is increasing 1 dB annually:

$\boxed{\text{The intensity level will double in 3 years.}}$

69 ••

Picture the Problem We can find the intensities of the three sources from their intensity levels and, because their intensities are additive, find the intensity level when all three sources are acting.

(*a*) Express the sound intensity level when the three sources act at the same time:

$$\beta_{3\,\text{sources}} = (10\,\text{dB})\log\frac{I_{3\,\text{sources}}}{I_0} = (10\,\text{dB})\log\frac{I_{70}+I_{73}+I_{80}}{I_0}$$

Find the intensities of each of the three sources:

$$70\,\text{dB} = (10\,\text{dB})\log\frac{I_{70}}{I_0} \Rightarrow I_{70} = 10^7 I_0$$

$$73\,\text{dB} = (10\,\text{dB})\log\frac{I_{73}}{I_0} \Rightarrow I_{73} = 10^{7.3} I_0$$

and

$$80\,\text{dB} = (10\,\text{dB})\log\frac{I_{80}}{I_0} \Rightarrow I_{80} = 10^8 I_0$$

Substitute and evaluate $\beta_{3\text{ sources}}$:

$$\beta_{3\,\text{sources}} = (10\,\text{dB})\log\frac{10^7 I_0 + 10^{7.3} I_0 + 10^8 I_0}{I_0} = (10\,\text{dB})\log\left(10^7 + 10^{7.3} + 10^8\right) = \boxed{81.1\,\text{dB}}$$

(*b*) Find the intensity level with the two least intense sources eliminated:

$$\beta_{80} = (10\,\text{dB})\log\frac{10^8 I_0}{I_0} = (10\,\text{dB})\log\left(10^8\right) = \boxed{80.0\,\text{dB}}$$

Eliminating the two least intense sources does not reduce the intensity level significantly.

***70** ••

Picture the Problem Let *P* be the power radiated by the source of sound, and *r* be the initial distance from the source to the receiver. We can use the definition of intensity to find the ratio of the intensities before and after the distance is doubled and then use the definition of the decibel level to find the change in its level.

Relate the change in decibel level to the change in the intensity level:

$$\Delta\beta = 10\log\frac{I}{I'}$$

Using its definition, express the intensity of the sound from the source as a function of P and r:

$$I = \frac{P}{4\pi r^2}$$

Express the intensity when the distance is doubled:

$$I' = \frac{P}{4\pi(2r)^2} = \frac{P}{16\pi r^2}$$

Evaluate the ratio of I to I':

$$\frac{I}{I'} = \frac{\frac{P}{4\pi r^2}}{\frac{P}{16\pi r^2}} = 4$$

Substitute to obtain:

$$\Delta\beta = 10\log 4 = 6.02\,\text{dB}$$

and $\boxed{(c)\text{ is correct.}}$

71 •••

Picture the Problem The sound level can be found from the intensity of the sound due to the talking people. When 38 people are talking, the intensities add.

Express the sound level when all 38 people are talking:

$$\begin{aligned}\beta_{38} &= (10\,\text{dB})\log\frac{38I_1}{I_0}\\ &= (10\,\text{dB})\log 38 + (10\,\text{dB})\log\frac{I_1}{I_0}\\ &= (10\,\text{dB})\log 38 + 72\,\text{dB}\\ &= \boxed{87.8\,\text{dB}}\end{aligned}$$

An equivalent but longer solution:

Express the sound level when all 38 people are talking:

$$\beta_{38} = (10\,\text{dB})\log\frac{38I_1}{I_0}$$

Express the sound level when only one person is talking:

$$\beta_1 = 72\,\text{dB} = (10\,\text{dB})\log\frac{I_1}{I_0}$$

Solve for and evaluate I_1:

$$\begin{aligned}I_1 &= 10^{7.2} I_0 = 10^{7.2}\left(10^{-12}\ \text{W/m}^2\right)\\ &= 1.58\times10^{-5}\ \text{W/m}^2\end{aligned}$$

Express the intensity when all 38 people are talking:

$$I_{38} = 38I_1$$

The decibel level is:

$$\beta_{38} = (10\,\text{dB})\log\frac{38(1.58\times10^{-5}\ \text{W/m}^2)}{10^{-12}\ \text{W/m}^2} = \boxed{87.8\,\text{dB}}$$

***72 •••**

Picture the Problem Let η represent the efficiency with which mechanical energy is converted to sound energy. Because we're given information regarding the rate at which mechanical energy is delivered to the string and the rate at which sound energy arrives at the location of the listener, we'll take the efficiency to be the ratio of the sound power delivered to the listener divided by the power delivered to the string. We can calculate the power input directly from the given data. We'll calculate the intensity of the sound at 35 m from its intensity level at that distance and use this result to find the power output.

Express the efficiency of the conversion of mechanical energy to sound energy:

$$\eta = \frac{P_{\text{out}}}{P_{\text{in}}}$$

Find the power delivered by the bow to the string:

$$P_{\text{in}} = Fv = (0.6\,\text{N})(0.5\,\text{m/s}) = 0.3\,\text{W}$$

Using $\beta = (10\,\text{dB})\log(I/I_0)$, find the intensity of the sound at 35 m:

$$60\,\text{dB} = (10\,\text{dB})\log\frac{I_{35\,\text{m}}}{I_0}$$

and

$$I_{35\,\text{m}} = 10^6 I_0 = 10^{-6}\ \text{W/m}^2$$

Find the power of the sound emitted:

$$P_{\text{out}} = IA = 4\pi(10^{-6}\ \text{W/m}^2)(35\,\text{m})^2 = 0.0154\,\text{W}$$

Substitute numerical values and evaluate η:

$$\eta = \frac{0.0154\,\text{W}}{0.3\,\text{W}} = \boxed{5.13\%}$$

73 •••

Picture the Problem Because the sound intensities are additive, we'll find the intensity due to one student by subtracting the background intensity from the intensity due to the students and dividing by 100. Then, we'll use this result to calculate the intensity level due to 50 students.

Express the intensity level due to 50 students:

$$\beta_{50} = (10\,\text{dB})\log\frac{50I_1}{I_0}$$

Find the sound intensity when 100 students are writing the exam:

$$60\,\text{dB} = (10\,\text{dB})\log\frac{I_{100}}{I_0}$$

and

$$I_{100} = 10^6 I_0 = 10^{-6}\ \text{W/m}^2$$

Find the sound intensity due to the background noise:

$$40\,\text{dB} = (10\,\text{dB})\log\frac{I_{\text{background}}}{I_0}$$

and

$$I_{\text{background}} = 10^4 I_0 = 10^{-8}\ \text{W/m}^2$$

Express the sound intensity due to the 100 students:

$$I_{100} - I_{\text{background}} = 10^{-6}\ \text{W/m}^2 - 10^{-8}\ \text{W/m}^2 \approx 10^{-6}\ \text{W/m}^2$$

Find the sound intensity due to 1 student:

$$\frac{I_{100} - I_{\text{background}}}{100} = 10^{-8}\ \text{W/m}^2$$

Substitute numerical values and evaluate the intensity level due to 50 students:

$$\beta_{50} = (10\,\text{dB})\log\frac{50(10^{-8}\ \text{W/m}^2)}{10^{-12}\ \text{W/m}^2} = \boxed{57.0\,\text{dB}}$$

The Doppler Effect

74 •

Picture the Problem We can use equation 15-32 ($\lambda = \dfrac{v \pm u}{f_s}$) to find the wavelength of the sound between the source and the listener and 15-35*a* ($f_r = \dfrac{v \pm u_r}{v \pm u_s} f_s$) to find the frequency heard by the listener.

(*a*) Because the source is approaching the listener, use the minus sign in the numerator of Equation 15-32 to find the wavelength of the sound between the source and the listener:

$$\lambda = \frac{340\,\text{m/s} - 80\,\text{m/s}}{200\,\text{s}^{-1}} = \boxed{1.30\,\text{m}}$$

(*b*) Because the listener is at rest and the source is approaching, $u_r = 0$ and the denominator of Equation 15-35<u>*a*</u> is the difference between the two speeds:

$$f_r = \frac{v}{v - u_s} f_s = \frac{340\,\text{m/s}}{340\,\text{m/s} - 80\,\text{m/s}}\left(200\,\text{s}^{-1}\right) = \boxed{262\,\text{Hz}}$$

75 •

Picture the Problem In the reference frame described, the speed of sound from the source to the listener is reduced by the speed of the wind. We can find the wavelength of the sound in the region between the source and the listener from $v = f\lambda$. Because the sound waves in the region between the source and the listener will be compressed by the motion of the listener, the frequency of the sound heard by the listener will be higher than the frequency emitted by the source and can be calculated using $f_r = \frac{v \pm u_r}{v \pm u_s} f_s$.

(*a*) The speed of sound in the reference frame of the source is:

$$v = 340\,\text{m/s} - 80\,\text{m/s} = \boxed{260\,\text{m/s}}$$

(*b*) Noting that the frequency is unchanged, express the wavelength of the sound:

$$\lambda = \frac{v}{f} = \frac{260\,\text{m/s}}{200\,\text{s}^{-1}} = \boxed{1.30\,\text{m}}$$

(*c*) Apply Equation 15-35*a* to obtain:

$$f_r = \left(\frac{v + u_r}{v}\right) f_s = \left(\frac{260\,\text{m/s} + 80\,\text{m/s}}{260\,\text{m/s}}\right)\left(200\,\text{s}^{-1}\right) = \boxed{262\,\text{Hz}}$$

76 •

Picture the Problem We can use $\lambda = (v \pm u)/f_s$ to find the wavelength of the sound in the region between the source and the listener and $f_r = \frac{v \pm u_r}{v \pm u_s} f_s$ to find the frequency heard by the listener. Because the sound waves in the region between the source and the listener will be spread out by the motion of the listener, the frequency of the sound heard by the listener will be lower than the frequency emitted by the source.

(*a*) Because the source is moving away from the listener, use the positive sign in the numerator of Equation 15-32 to find the wavelength of the sound between the source and the listener:

$$\lambda = \frac{340\,\text{m/s} + 80\,\text{m/s}}{200\,\text{s}^{-1}} = \boxed{2.10\,\text{m}}$$

(*b*) Because the listener is at rest and the source is receding, $u_r = 0$ and the denominator of Equation 15-35*a* is the sum of the two speeds:

$$f_r = \frac{v}{v + u_s} f_s = \frac{340\,\text{m/s}}{340\,\text{m/s} + 80\,\text{m/s}}\left(200\,\text{s}^{-1}\right) = \boxed{162\,\text{Hz}}$$

77 •

Picture the Problem We can find the wavelength of the sound in the region between the source and the listener from $v = f\lambda$. Because the sound waves in the region between the source and the listener will be compressed by the motion of the listener, the frequency of the sound heard by the listener will be higher than the frequency emitted by the source and can be calculated using $f_r = \frac{v \pm u_r}{v \pm u_s} f_s$.

(*a*) Because the wavelength is unaffected by the motion of the observer:

$$\lambda = \frac{v}{f} = \frac{340\,\text{m/s}}{200\,\text{s}^{-1}} = \boxed{1.70\,\text{m}}$$

(*b*) Apply Equation 15-35*a* to obtain:

$$f_r = \left(\frac{v + u_r}{v}\right) f_0 = \left(\frac{340\,\text{m/s} + 80\,\text{m/s}}{340\,\text{m/s}}\right)\left(200\,\text{s}^{-1}\right) = \boxed{247\,\text{Hz}}$$

78 •

Picture the Problem In this reference frame, the speed of sound will be increased by the speed of the listener. We can find the wavelength of the sound in the region between the source and the listener from $v = f\lambda$. Because the sound waves in the region between the source and the listener will be compressed by the motion of the listener, the frequency of the sound heard by the listener will be higher than the frequency emitted by the source and can be calculated using $v' = f_r\lambda'$.

(*a*) Moving at 80 m/s in still air: The observer experiences a wind velocity of 80 m/s.

(*b*) Use the standard Galilean transformation to obtain:

$$v' = v + u_r = 340\text{ m/s} + 80\text{ m/s} = \boxed{420\text{ m/s}}$$

(*c*) Because the distance between the wave crests is unchanged:

$$\lambda' = \frac{v'}{f} = \frac{340\text{ m/s}}{200\text{ s}^{-1}} = \boxed{1.70\text{ m}}$$

(*d*) Using the speed of sound in this reference frame, express and evaluate the frequency heard by the listener:

$$f_r = \frac{v'}{\lambda'} = \frac{420\text{ m/s}}{1.70\text{ m}} = \boxed{247\text{ Hz}}$$

79 •

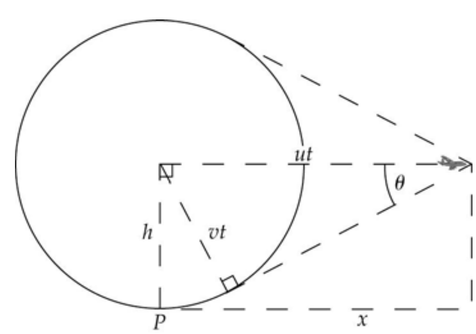
Picture the Problem Because the listener is moving away from the source, we know that the frequency he/she will hear will be less than the frequency emitted by the source. We can use $f_r = \frac{v \pm u_r}{v \pm u_s} f_s$, with $u_s = 0$ and the minus sign in the numerator, to determine its value.

Relate the frequency heard by the listener to that of the source:

$$f_r = \left(\frac{v - u_r}{v}\right) f_s = \left(\frac{340\text{ m/s} - 80\text{ m/s}}{340\text{ m/s}}\right)\left(200\text{ s}^{-1}\right) = \boxed{153\text{ Hz}}$$

80 •

Picture the Problem The diagram shows the position of the supersonic plane at time *t* after it was directly over a person located at point *P* 5000 m below it. Let *u* represent the speed of the plane and *v* the speed of sound. We can use trigonometry to determine the angle of the shock wave as well as the location of the jet *x* when the person on the ground hears the shock wave.



(*a*) Referring to the diagram, express θ in terms of *v, u,* and *t*:

$$\theta = \sin^{-1}\left(\frac{vt}{ut}\right) = \sin^{-1}\left(\frac{1}{u/v}\right) = \sin^{-1}\left(\frac{1}{2.5}\right) = \boxed{23.6°}$$

(*b*) Using the diagram, relate the angle θ to the altitude *h* of the plane and the distance *x* and solve for *x*:

$$\tan\theta = \frac{h}{x} \Rightarrow x = \frac{h}{\tan\theta}$$

Substitute numerical values and evaluate *x*:

$$x = \frac{5000\,\text{m}}{\tan 23.6°} = \boxed{11.4\,\text{km}}$$

81 •

Picture the Problem If both u_s and u_r are much smaller than the speed of sound *v,* then the shift in frequency is given approximately by $\frac{\Delta f}{f_r} = \pm\frac{u}{v}$, where $u = u_s \pm u_r$ is the relative speed of the source and receiver. For purposes of this problem, we'll assume that you are an Olympics qualifier and can run at a top speed of approximately 10 m/s.

Express the frequency, f_r, you hear in terms of the frequency of the source f_s and your running speed *u*:

$$f_r = \left(\frac{v+u}{v}\right)f_s$$

Assuming that you can run 10 m/s , substitute numerical values and evaluate f_r:

$$f_r = \left(\frac{340\,\text{m/s} + 10\,\text{m/s}}{340\,\text{m/s}}\right)(1000\,\text{Hz}) = \boxed{1029\,\text{Hz}}$$

Using the positive sign (you are approaching the source), express and evaluate the ratio $\frac{\Delta f}{f_r}$:

$$\frac{\Delta f}{f_r} = \frac{10\,\text{m/s}}{340\,\text{m/s}} = 2.94\%$$

Because this fractional change in frequency is less than the 3% criterion for recognition of a change in frequency, it would be *impossible* to use your sense of pitch to estimate your running speed.

82 ••

Picture the Problem Because the car is moving away from the radar device, the frequency f_r it receives will be less than the frequency emitted by the device. The microwaves reflected from the car, moving away from a stationary detector, will be of a still lower frequency f_r'. We can use the Doppler shift equations to derive an expression for the speed of the car in terms of difference of these frequencies.

Express the frequency f_r received by the moving car in terms of f_s, *u,* and *v*:

$$f_r = \left(\frac{c-u}{c}\right)f_s \qquad (1)$$

Express the frequency f_r' received by the stationary source in terms of f_r, *u,* and *v*:

$$f_r' = \left(\frac{c-u}{c}\right)f_r \qquad (2)$$

Substitute equation (1) in equation (2) to eliminate f_r:

$$f_r' = \left(\frac{c-u}{c}\right)^2 f_s \approx \left(1-\frac{2u}{c}\right)f_s$$

provided $u << c$

Express the frequency difference detected at the source:

$$\Delta f = f_s - f_r' = f_s - \left(1-\frac{2u}{c}\right)f_s$$

$$= \frac{2u}{c}f_s$$

Solve for *u*:

$$u = \frac{c}{2f_s}\Delta f$$

Substitute numerical values and evaluate *u*:

$$u = \frac{3\times10^8\ \text{m/s}}{2(2\ \text{GHz})}(293\ \text{Hz})$$

$$= 22.0\frac{\text{m}}{\text{s}}\times\frac{1\ \text{km}}{10^3\ \text{m}}\times\frac{3600\ \text{s}}{\text{h}}$$

$$= \boxed{79.1\ \text{km/h}}$$

***83 ••**

Picture the Problem Because the radial component *u* of the velocity of the raindrops is small compared to the speed $v = c$ of the radar pulse, we can approximate the fractional change in the frequency of the reflected radar pulse to find the speed of the winds carrying the raindrops in the storm system.

Express the shift in frequency when the speed of the source (the storm system) *u* is much smaller than the wave speed $v = c$:

$$\frac{\Delta f}{f_s} \approx \frac{u}{c}$$

Solve for u:

$$u = c\frac{\Delta f}{f_s}$$

Substitute numerical values and evaluate u:

$$u = (2.998\times10^8\ \text{m/s})\frac{325\,\text{Hz}}{625\,\text{MHz}}$$
$$= 156\,\text{m/s}\times\frac{0.6215\,\text{mi/h}}{0.2778\,\text{m/s}}$$
$$= \boxed{349\,\text{mi/h}}$$

84 ••

Picture the Problem Let the depth of the submarine be represented by D and its vertical speed by u. The submarine acts as both a receiver and source. We can apply the definition of average speed to determine the depth of the submarine and use the Doppler shift equations to derive an expression for the vertical speed of the submarine in terms of the frequency difference.

(*a*) Using the definition of average speed, relate the depth of the submarine to the time delay between the transmitted and reflected pulses:

$$2D = v\Delta t \Rightarrow D = \tfrac{1}{2}v\Delta t$$

Substitute numerical values and evaluate D:

$$D = \tfrac{1}{2}(1.54\,\text{km/s})(80\,\text{ms}) = \boxed{61.6\,\text{m}}$$

(*b*) Express the frequency f_r received by the submarine in terms of f_0, u, and c:

$$f_r = \left(\frac{c\pm u}{c}\right)f_s \qquad (1)$$

Express the frequency f_r' received by the destroyer in terms of f_r, u, and c:

$$f_r' = \left(\frac{c\pm u}{c}\right)f_r \qquad (2)$$

Substitute equation (1) in equation (2) to eliminate f_r:

$$f_r' = \left(\frac{c\pm u}{c}\right)^2 f_s \approx \left(1\pm\frac{2u}{c}\right)f_s$$

provided $u << c$.

Express the frequency difference detected by the destroyer:

$$\Delta f = f_s - f_r' = f_s - \left(1\pm\frac{2u}{c}\right)f_s$$
$$= \frac{2u}{c}f_s$$

Solve for u:

$$u = \frac{c}{2f_s}\Delta f$$

Substitute numerical values and evaluate u:

$$u = \frac{1.54\,\text{km/s}}{2(40\,\text{MHz})}(0.0420\,\text{MHz}) = \boxed{0.809\,\text{m/s}}$$

where the positive speed indicates that the velocity of the submarine is downward.

85 ••

Picture the Problem Because the car is moving away from the radar unit, the frequency f_r it receives will be less than the frequency emitted by the unit. The radar waves reflected from the car, moving away from a stationary detector, will be of a still lower frequency f_r'. Let u represent the relative speed of the police car and the receding car (140 km/h) and use the Doppler shift equations to derive an expression for the difference between f_s, the transmitted signal, and f_r'.

Express the frequency f_r received by the moving car in terms of f_s, u, and c:

$$f_r = \left(\frac{c-u}{c}\right)f_s \qquad (1)$$

Express the frequency f_r' received by the stationary source in terms of f_r, u, and c:

$$f'_r = \left(\frac{c-u}{c}\right)f_r \qquad (2)$$

Substitute equation (1) in equation (2) to eliminate f_r:

$$f_r' = \left(1-\frac{u}{c}\right)^2 f_s \approx \left(1-\frac{2u}{c}\right)f_s$$

provided $u \ll c$

Express the frequency difference detected at the source:

$$\Delta f = f_s - f'_r = f_s - \left(1-\frac{2u}{c}\right)f_s = \frac{2u}{c}f_s$$

Substitute numerical values and evaluate Δf:

$$\Delta f = \left[\frac{2\left(140\,\frac{\text{km}}{\text{h}}\times\frac{1\,\text{h}}{3600\,\text{s}}\right)}{3\times10^8\,\text{m/s}}\right](3\times10^{10}\,\text{Hz}) = \boxed{7.78\,\text{kHz}}$$

86 ••

Picture the Problem Because the car is moving away from the radar unit, the frequency f_r it receives will be less than the frequency emitted by the unit. The radar waves reflected from the car, moving away from a stationary detector, will be of a still lower frequency f_r'. Let u represent the relative speed of the police car and the receding car (80 km/h) and use the Doppler shift equations to derive an expression for the difference between f_s, the transmitted signal, and f_r'.

Express the frequency f_r received by the moving car in terms of f_s, u, and c:

$$f_r = \left(\frac{c-u}{c}\right) f_s \qquad (1)$$

Express the frequency f_r' received by the stationary source in terms of f_r, u, and c:

$$f_r' = \left(\frac{c-u}{c}\right) f_r \qquad (2)$$

Substitute equation (1) in equation (2) to eliminate f_r:

$$f_r' = \left(1-\frac{u}{c}\right)^2 f_s \approx \left(1-\frac{2u}{c}\right) f_s$$

provided $u << c$.

Express the frequency difference detected at the source:

$$\Delta f = f_s - f_r' = f_s - \left(1-\frac{2u}{c}\right) fs_0$$

$$= \frac{2u}{c} f_s$$

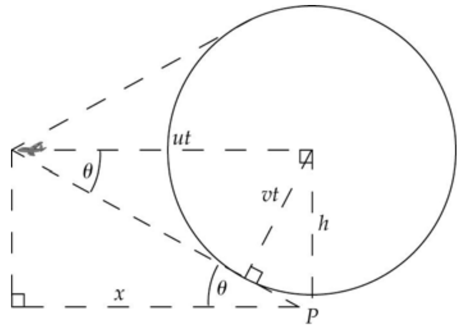
Substitute numerical values and evaluate Δf:

$$\Delta f = \left[\frac{2\left(80\frac{\text{km}}{\text{h}}\times\frac{1\,\text{h}}{3600\,\text{s}}\right)}{3\times10^8\ \text{m/s}}\right]\left(3\times10^{10}\ \text{Hz}\right)$$

$$= \boxed{4.44\,\text{kHz}}$$

87 ••

Picture the Problem The diagram shows the position of the supersonic plane flying due west at time *t* after it was directly over point *P* 12 km below it. Let *x* be measured from point *P*, *u* represent the speed of the plane, and *v* be the speed of sound. We can use trigonometry to determine the angle of the shock wave as well as the location of the jet *x* when the person on the ground hears the shock wave.



Using the diagram to relate the distance x to the shock-wave angle θ and the elevation of the plane:

$$\tan\theta = \frac{h}{x} \text{ and } x = \frac{h}{\tan\theta}$$

Referring to the diagram, express θ in terms of *v, u,* and *t* and determine its value:

$$\theta = \sin^{-1}\left(\frac{vt}{ut}\right) = \sin^{-1}\left(\frac{1}{u/v}\right) = \sin^{-1}\left(\frac{1}{1.6}\right) = 38.7°$$

Substitute numerical values and evaluate *x*:

$$x = \frac{12\,\text{km}}{\tan 38.7°} = \boxed{15.0\,\text{km west of } P.}$$

88 ••

Picture the Problem The change in frequency of source as it oscillates on the air track is 3 Hz. We can use $\frac{\Delta f}{f_s} \approx \pm\frac{u}{v}$ to find the maximum speed of the vibrating mass-spring system in terms of this change in frequency and then use this speed to find the energy of the system. Knowing the energy of the system, we can find the amplitude of its motion. We can calculate the period of the motion from knowledge of the mass of the radio and the stiffness constant of the spring.

(*a*) Express the energy of the vibrating mass-spring system in terms of its maximum speed:

$$E = \tfrac{1}{2} m u_{\text{max}}^2 \qquad (1)$$

Relate the change in the frequency heard by the listener to the maximum speed of the oscillator:

$$\frac{\Delta f}{f_s} = \pm\frac{u}{v}$$

where $u = u_s \pm u_r$ is the relative speed of the source and receiver and v is the speed of sound.

Solve for and evaluate $u = u_{max}$:

$$u_{max} = \frac{\Delta f}{f_0} v = \frac{3\,\text{Hz}}{800\,\text{Hz}}(340\,\text{m/s}) = 1.275\,\text{m/s}$$

Substitute numerical values in equation (1) and evaluate E:

$$E = \tfrac{1}{2}(0.1\,\text{kg})(1.275\,\text{m/s}^2)^2 = \boxed{81.3\,\text{mJ}}$$

(b) Relate the energy of the oscillator to the amplitude of its motion:

$$E = \tfrac{1}{2}kA^2$$

Solve for A to obtain:

$$A = \sqrt{\frac{2E}{k}}$$

Substitute numerical values and evaluate A:

$$A = \sqrt{\frac{2(81.3\,\text{mJ})}{200\,\text{N/m}}} = \boxed{2.85\,\text{cm}}$$

89 ••

Picture the Problem The received and transmitted frequencies are related through $f_r = \frac{v \pm u_r}{v \pm u_s} f_s$, where the variables have the meanings given in the problem statement. Because the source and receiver are moving in the same direction, we use the minus signs in both the numerator and denominator.

(a) Relate the received frequency f_r to the frequency f_0 of the source:

$$f_r = \frac{1 - u_r/v}{1 - u_s/v} f_0 = \boxed{(1 - u_r/v)(1 - u_s/v)^{-1} f_0}$$

(b) Apply the binomial expansion to $(1 - u_s/v)^{-1}$:

$$(1 - u_s/v)^{-1} \approx 1 + u_s/v$$

Substitute to obtain:

$$f_r = (1 - u_r/v)(1 + u_s/v) f_0 = [1 + u_s/v - u_r/v - (u_r/v)(u_s/v)] f_0 \approx \left(1 + \frac{u_s - u_r}{v}\right)$$

because both u_s and u_r are small compared to v.

Because $u_{rel} = u_s - u_r$

$$f_r' \approx \boxed{\left(1+\frac{u_{rel}}{v}\right)f_0}$$

90 ••

Picture the Problem Because the students are walking away from each other, the frequency f' each receives will be less than the frequency f_s = 440 Hz emitted by their tuning forks. Let u represent the speed of each student and use the Doppler shift equations to derive an expression for the difference between f_s, the frequency of the tuning fork each carries, and the frequency heard from the other's tuning fork. Because this equation will contain u, we'll be able to solve for and evaluate each student's walking speed.

Using equation 15-35*a*, express the frequency f_r received by either student, when they are walking away from each other, in terms of f_s, u, and v:

$$f_r = \frac{1-u/v}{1+u/v}f_s = (1-u/v)(1+u/v)^{-1}f_s$$

Expand $(1+u/v)^{-1}$ binomially:

$$(1+u/v)^{-1} \approx 1-u/v \text{ provided } u << v.$$

Substitute and simplify to obtain:

$$f_r = (1-u/v)^2 f_s = \left(1-2u/v+u^2/v^2\right)f_s \approx (1-2u/v)f_s$$

for $u << v$.

Express the frequency difference heard by each student:

$$\Delta f = f_0 - f_r = f_s - \left(1-\frac{2u}{v}\right)f_s = \frac{2u}{v}f_s$$

Solve for u:

$$u = \frac{\Delta f}{2f_s}v$$

Substitute numerical values and evaluate u:

$$u = \frac{2\text{ Hz}}{2(440\text{ Hz})}(340\text{ m/s}) = \boxed{0.773\text{ m/s}}$$

91 ••

Picture the Problem The student serves as a source moving toward the wall, and a moving receiver for the echo. The received and transmitted frequencies are related through $f_r = \frac{v \pm u_r}{v \pm u_s}f_s$. We'll express the frequency received by the wall and the frequency it transmits back to the moving student in order to express the difference in the frequency the student hears from the wall and frequency she hears directly from her tuning fork. Because this expression will contain the student's walking speed, we'll be able to solve for and evaluate this speed.

Relate the frequency f_r received by the wall to the frequency of the student's tuning fork f_s:

$$\Delta f = f_s - f_r' = f_s - \left(1 - \frac{2u}{c}\right) f_s = \frac{2u}{c} f_s$$

Because the source is moving toward a stationary receiver:

$$f_r = \frac{1}{1 - u_s/v} f_s = (1 - u_s/v)^{-1} f_s$$

Apply the binomial expansion to $(1 - u_s/v)^{-1}$:

$$(1 - u_s/v)^{-1} \approx 1 + u_s/v$$

because $u_s << v$.

Substitute to obtain:

$$f_r = (1 + u_s/v) f_0$$

Relate the frequency f_r' reflected from the wall and received by the student to the frequency f_r reflected from the wall:

$$f_r' = \frac{1 \pm u_r/v}{1 \pm u_s/v} f_r = \frac{1}{1 - u_s/v} f_r$$

because the source (the wall) is at rest and the receiver is approaching.

Substitute for f_r to obtain:

$$f_r' = \frac{1}{1 - u_s/v}(1 + u_s/v) f_s = (1 + u_s/v)(1 - u_s/v)^{-1} f_s$$

Expand $(1 - u_s/v)^{-1}$ binomially:

$$(1 - u_s/v)^{-1} \approx 1 + u_s/v$$

because $u_s << v$.

$$f_r' = (1 + u_s/v)(1 + u_s/v) f_s \approx (1 + 2u_s/v) f_s$$

because $u_s << v$

Express the difference between the frequency the student receives from the wall and the frequency of her tuning fork:

$$\Delta f = f_r' - f_s = (1 + 2u_s/v) f_s - f_s = \frac{2u_s}{v} f_s$$

Solve for u_s:

$$u_s = \frac{\Delta f}{2f_s}v$$

Substitute numerical values and evaluate u_s:

$$u_s = \frac{4\,\text{Hz}}{2(512\,\text{Hz})}(340\,\text{m/s}) = \boxed{1.33\,\text{m/s}}$$

***92 ••**

Picture the Problem The frequency heard by the stationary observer will vary with time as the speaker rotates on its support arm. We can use a Doppler equation to express the frequency heard by the observer as a function of the velocity of the source and find the velocity of the source from the expression for the tangential velocity of an object moving in a circular path.

Express the frequency f_r heard by a stationary observer:

$$f_r = \frac{1}{1-u_s/v}f_s = (1-u_s/v)^{-1}f_s$$

Expand $(1-u_s/v)^{-1}$ to obtain:

$$(1-u_s/v)^{-1} \approx 1+u_s/v$$

because $u_s/v << 1$

Substitute in the expression for f_r:

$$f_r = (1+u_s/v)f_s \qquad (1)$$

Express the speed of the source as a function of time:

$$\begin{aligned} u_s &= r\omega\sin\omega t \\ &= (0.8\,\text{m})(4\,\text{rad/s})\sin[(4\,\text{rad/s})t] \\ &= (3.2\,\text{m/s})\sin[(4\,\text{rad/s})t] \end{aligned}$$

Substitute in equation (1) to obtain:

$$f_r = \left(1+\frac{3.2\,\text{m/s}}{v}\sin[(4\,\text{rad/s})t]\right)f_s$$

Substitute for v and simplify:

$$\begin{aligned} f_r &= \left(1+\frac{3.2\,\text{m/s}}{340\,\text{m/s}}\sin[(4\,\text{rad/s})t]\right)(1000\,\text{s}^{-1}) \\ &= \boxed{1000\,\text{Hz}+(9.41\,\text{Hz})\sin[(4\,\text{rad/s})t]} \end{aligned}$$

93 ••

Picture the Problem The simplest way to approach this problem is to transform to a reference frame in which the balloon is at rest. In that reference frame, the speed of sound is v = 340 m/s, and u_r = 36 km/h = 10 m/s. Then, we can use the equations for a moving receiver and a moving source to find the frequencies heard at the window and on the balloon.

(*a*) Express the observed frequency in terms of the frequency of the source:

$$f_r = \left(1 + \frac{u_r}{v}\right) f_s$$

Substitute numerical values and evaluate f_r:

$$f_r = \left(1 + \frac{10\,\text{m/s}}{340\,\text{m/s}}\right)(800\,\text{Hz}) = \boxed{824\,\text{Hz}}$$

(*b*) Treating the tall building as a moving source, express the frequency of the reflected sound heard by a person riding in the balloon:

$$f_r' = \left(\frac{1}{1 - \frac{u_s}{v}}\right) f_r$$

Substitute numerical values and evaluate f_r':

$$f_r' = \left(\frac{1}{1 - \frac{10\,\text{m/s}}{340\,\text{m/s}}}\right)(824\,\text{Hz}) = \boxed{849\,\text{Hz}}$$

94 ••

Picture the Problem We can relate the frequencies f_r and f_r' heard by the stationary observer behind the car to the speed of the car *u* and the frequency of the car's horn f_s. Dividing these equations will eliminate the frequency of the car's horn and allow us to solve for the speed of the car. We can then substitute to find the frequency of the car's horn. We can find the frequency heard by the driver as a moving receiver by relating this frequency to the frequency reflected from the wall.

(*a*) Relate the frequency heard by the observer directly from the car's horn to the speed of the car:

$$f_r = \frac{1}{1 + u/v} f_s \qquad (1)$$

Relate the frequency reflected from the wall to the speed of the car:

$$f_r' = \frac{1}{1 - u/v} f_s \qquad (2)$$

Divide equation (2) by equation (1) to obtain:

$$\frac{f_r'}{f_r} = \frac{1 + u/v}{1 - u/v}$$

Solve for *u*:

$$u = \frac{f_r' - f_r}{f_r' + f_r'} v$$

Substitute numerical values and evaluate u:

$$u = \frac{863\,\text{Hz} - 745\,\text{Hz}}{863\,\text{Hz} + 745\,\text{Hz}}(340\,\text{m/s})$$
$$= 24.95\frac{\text{m}}{\text{s}} \times \frac{1\,\text{km}}{10^3\,\text{m}} \times \frac{3600\,\text{s}}{\text{h}}$$
$$= \boxed{89.8\,\text{km/h}}$$

(*b*) Solve equation (1) for f_s:

$$f_s = (1 + u/v)f_r$$

Substitute numerical values and evaluate f_s:

$$f_s = \left(1 + \frac{24.95\,\text{m/s}}{340\,\text{m/s}}\right)(745\,\text{Hz})$$
$$= \boxed{800\,\text{Hz}}$$

(*c*) The driver is a moving receiver and so we can relate the frequency heard by the driver to the frequency reflected by the wall (the frequency heard by the stationary observer):

$$f_{\text{driver}} = \left(1 + \frac{u}{v}\right)f_r'$$

Substitute numerical values and evaluate f_{driver}:

$$f_{\text{driver}} = \left(1 + \frac{24.95\,\text{m/s}}{340\,\text{m/s}}\right)(863\,\text{Hz})$$
$$= \boxed{926\,\text{Hz}}$$

95 ••

Picture the Problem Let $t = 0$ when the driver sounds her horn and let the distance to the cliff at that instant be d. The received and transmitted frequencies are related through $f_r = \frac{v \pm u_r}{v \pm u_s} f_s$. Solving this equation for f_s will allow us to determine the frequency of the car horn. We can use the total distance the sound travels (car-to-cliff plus cliff back to car … now closer to the cliff) to determine the distance to the cliff when the horn was briefly sounded.

Relate the frequency heard by the driver to her speed and to the frequency of her horn:

$$f_r = \frac{1 + u_r/v}{1 - u_s/v} f_s$$

Solve for f_s:

$$f_s = \frac{1 - u_s/v}{1 + u_r/v} f_r$$

Substitute numerical values and evaluate f_s:

$$f_0 = \frac{1 - \dfrac{100\dfrac{\text{km}}{\text{h}} \times \dfrac{1\,\text{h}}{3600\,\text{s}}}{340\,\text{m/s}}}{1 + \dfrac{100\dfrac{\text{km}}{\text{h}} \times \dfrac{1\,\text{h}}{3600\,\text{s}}}{340\,\text{m/s}}}(840\,\text{Hz}) = \frac{1 - \dfrac{27.78\,\text{m/s}}{340\,\text{m/s}}}{1 + \dfrac{27.78\,\text{m/s}}{340\,\text{m/s}}}(840\,\text{Hz}) = 713\,\text{Hz}$$

Relate the distance d to the cliff at $t = 0$ to the distance she travels in time $\Delta t = 1$ s, her speed u, and the speed of sound v:

$$d + (d - u\Delta t) = v\Delta t$$

Solve for d:

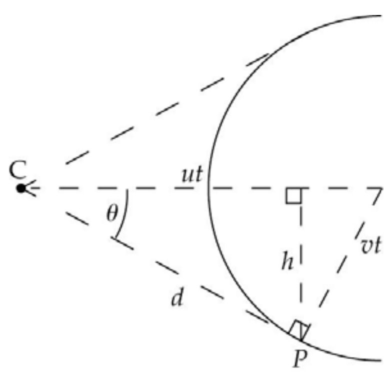
$$d = \tfrac{1}{2}(u + v)\Delta t$$

Substitute numerical values and evaluate d:

$$d = \tfrac{1}{2}(27.78\,\text{m/s} + 340\,\text{m/s})(1\,\text{s}) = \boxed{184\,\text{m}}$$

96 ••

Picture the Problem You'll year the sonic boom when the surface of its cone reaches your plane. In the diagram the Concorde is at C and your plane is at P. The distance $h = 3$ km. The distance between the planes when you hear the sonic boom is d. We can use trigonometry to determine the angle of the shock wave as well as the separation of the planes when you hear the sonic boom.



Using the Pythagorean theorem, relate the separation of the planes d, to the distance h and the angle θ:

$$d^2 = h^2 + d^2\cos^2\theta$$

Solve for d to obtain:

$$d = h\sqrt{\frac{1}{1 - \cos^2\theta}}$$

Express θ in terms of v, u, and t:

$$\theta = \sin^{-1}\left(\frac{vt}{ut}\right) = \sin^{-1}\left(\frac{1}{u/v}\right)$$

Substitute numerical values and evaluate θ:

$$\theta = \sin^{-1}\left(\frac{1}{1.6}\right) = \boxed{38.7°}$$

Substitute numerical values and evaluate *h*:

$$d = (3\,\text{km})\sqrt{\frac{1}{1-\cos^2 38.7°}} = \boxed{4.80\,\text{km}}$$

***97 ••**

Picture the Problem The sun and Jupiter orbit about their effective mass located at their common center of mass. We can apply Newton's 2nd law to the sun to obtain an expression for its orbital speed about the sun-Jupiter center of mass and then use this speed in the Doppler shift equation to estimate the maximum and minimum wavelengths resulting from the Jupiter-induced motion of the sun.

Letting *v* be the orbital speed of the sun about the center of mass of the sun-Jupiter system, express the Doppler shift of the light due to this motion when the sun is approaching the earth:

$$f' = \frac{c}{\lambda'} = f\sqrt{\frac{1+v/c}{1-v/c}} = \frac{c}{\lambda}\sqrt{\frac{1+v/c}{1-v/c}}$$

Solve for λ':

$$\lambda' = \lambda\sqrt{\frac{1-v/c}{1+v/c}}$$
$$= \lambda\sqrt{(1-v/c)(1+v/c)^{-1}}$$
$$= \lambda(1-v/c)^{1/2}(1+v/c)^{-1/2}$$

Because $v << c$, we can expand $(1-v/c)^{1/2}$ and $(1+v/c)^{-1/2}$ binomially to obtain:

$$(1-v/c)^{1/2} \approx 1-\frac{v}{2c}$$

and

$$(1+v/c)^{-1/2} \approx 1-\frac{v}{2c}$$

Substitute to obtain:

$$\sqrt{\frac{1-v/c}{1+v/c}} = \left(1-\frac{v}{2c}\right)^2 \approx 1-\frac{v}{c}$$

When the sun is receding from the earth:

$$\sqrt{\frac{1+v/c}{1-v/c}} = \left(1+\frac{v}{2c}\right)^2 \approx 1+\frac{v}{c}$$

Hence the motion of the sun will give an observed Doppler shift of:

$$\lambda' \approx \lambda\left(1 \pm \frac{v}{c}\right) \qquad (1)$$

Apply Newton's 2nd law to the sun:

$$\frac{GM_S M_{\text{eff}}}{r_{\text{cm}}^2} = M_S \frac{v^2}{r_{\text{cm}}}$$

Solve for v to obtain:

$$v = \sqrt{\frac{GM_{\text{eff}}}{r_{\text{cm}}}}$$

Measured from the center of the sun, the distance to the center of mass of the sun-Jupiter system is:

$$r_{\text{cm}} = \frac{(0)M_S + r_{\text{s-J}} M_J}{M_s + M_J} = \frac{r_{\text{s-J}} M_J}{M_s + M_J}$$

The effective mass is related to the masses of the sun and Jupiter according to:

$$\frac{1}{M_{\text{eff}}} = \frac{1}{M_s} + \frac{1}{M_J}$$

or

$$M_{\text{eff}} = \frac{M_s M_J}{M_s + M_J}$$

Substitute for M_{eff} and r_{cm} to obtain:

$$v = \sqrt{\frac{G\dfrac{M_s M_J}{M_s + M_J}}{\dfrac{r_{\text{s-J}} M_J}{M_s + M_J}}} = \sqrt{\frac{GM_s}{r_{\text{s-J}}}}$$

Using $r_{\text{s-J}} = 7.78\times10^{11}$ m as the mean orbital radius of Jupiter, substitute numerical values and evaluate v:

$$v = \sqrt{\frac{(6.673\times10^{-11}\ \text{N}\cdot\text{m}^2/\text{kg}^2)(1.99\times10^{30}\ \text{kg})}{7.78\times10^{11}\ \text{m}}} = 1.306\times10^4\ \text{m/s}$$

Substitute in equation (1) to obtain:

$$\lambda' \approx (500\ \text{nm})\left(1 \pm \frac{1.306\times10^4\ \text{m/s}}{2.998\times10^8\ \text{m/s}}\right) = (500\ \text{nm})(1 \pm 4.36\times10^{-5})$$

The maximum and minimum wavelengths are:

$$\lambda_{\max} = \boxed{(500\ \text{nm})(1 + 4.36\times10^{-5})}$$

and

$$\lambda_{\min} = \boxed{(500\ \text{nm})(1 - 4.36\times10^{-5})}$$

98 •••

Picture the Problem Choose a coordinate system in which downward is the positive y direction. Let d represent the distance the tuning fork has fallen when the student hears a frequency of 400 Hz, t_1 the time for the source to fall that distance, and t_2 the time for the sound to travel back to the student. We can a constant-acceleration equation to express d in terms of the time that elapses between the dropping of the tuning fork and the return of the sound to the student. A Doppler-effect equation will allow us to solve for the speed of the tuning fork when the student hears a frequency of 400 Hz; we can use constant-acceleration equations to find the fall time for the fork and the return time for the sound from the tuning fork.

Using a constant-acceleration equation, relate the distance the source has fallen to the elapsed time:

$$d = v_0 t + \tfrac{1}{2}at^2$$

or, because $v_0 = 0$ and $a = g$,

$$d = \tfrac{1}{2}gt^2 \qquad (1)$$

where $t = t_1 + t_2$.

Relate the frequency f_r heard by the student to the speed of the falling tuning fork:

$$f_r = \frac{1}{1 + u_s/v} f_s$$

Solve for u_s:

$$u_s = \left(\frac{f_s}{f_r} - 1\right)v$$

Substitute numerical values and evaluate u_s:

$$u_s = \left(\frac{440\ \text{Hz}}{400\ \text{Hz}} - 1\right)(340\ \text{m/s}) = 34.0\ \text{m/s}$$

Letting y be the distance the fork has fallen when its speed is u_s, use a constant-acceleration equation to relate y and u_s:

$$u_s^2 = v_0^2 + 2gy$$

or, because $v_0 = 0$,

$$u_s^2 = 2gy$$

Solve for y:

$$y = \frac{u_s^2}{2g}$$

Substitute numerical values and evaluate y:

$$y = \frac{(34\ \text{m/s})^2}{2(9.81\ \text{m/s}^2)} = 58.92\ \text{m}$$

Using a constant-acceleration equation, relate the speed of the falling tuning fork to its time of fall t_1:

$$u_s = v_0 + gt_1$$

or, because $v_0 = 0$,

$$u_s = gt_1$$

Solve for and evaluate t_1:

$$t_1 = \frac{u_s}{g} = \frac{34.0\ \text{m/s}}{9.81\ \text{m/s}^2} = 3.466\ \text{s}$$

Using the relationship between distance traveled, time and average speed, find the time t_2 for the sound to travel back to the student:

$$t_2 = \frac{y}{v} = \frac{58.92\,\text{m}}{340\,\text{m/s}} = 0.173\,\text{s}$$

Substitute in equation (1) and evaluate d:

$$d = \tfrac{1}{2}\left(9.81\,\text{m/s}^2\right)\left(3.466\,\text{s} + 0.173\,\text{s}\right)^2 = \boxed{65.0\,\text{m}}$$

99 ••

Picture the Problem The angle θ of the Cerenkov shock wave is related to the speed of light in water v and the speed of light in a vacuum c according to $\sin\theta = v/c$.

Relate the speed of light in water v to the angle of the Cerenkov cone:

$$\sin\theta = \frac{v}{c}$$

Solve for v:

$$v = c\sin\theta$$

Substitute numerical values and evaluate v:

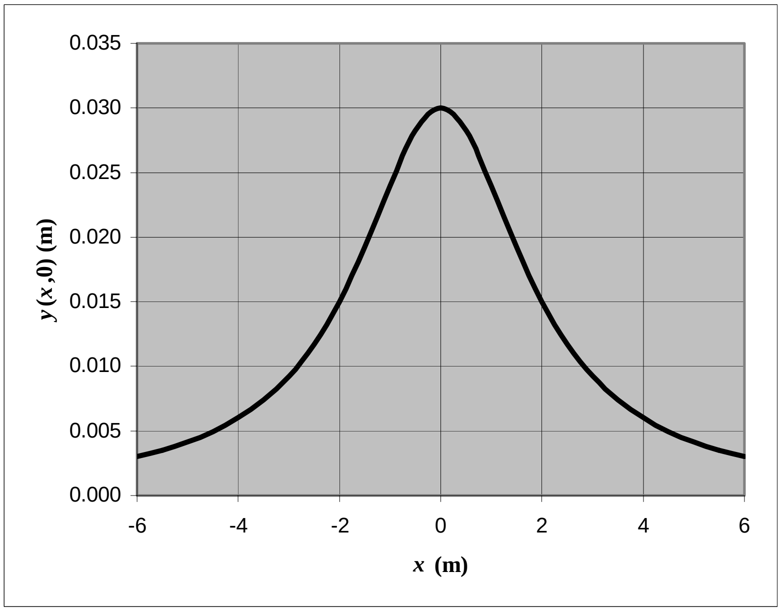
$$v = \left(2.998\times10^8\ \text{m/s}\right)\sin 48.75° = \boxed{2.25\times10^8\ \text{m/s}}$$

General Problems

100 •

Picture the Problem The equation of a wave traveling in the positive x direction is of the form $y(x,t) = f(x - vt)$ and that of a wave traveling in the negative x direction is $y(x,t) = f(x + vt)$.

(a) The pulse at $t = 0$ shown below was plotted using a spreadsheet program:



(b) The wave function must be of the form:

$$y(x,t) = f(x - vt) = f[x - (10\,\text{m/s})t]$$

because $v = 10$ m/s

Replace x with $x - (10\,\text{m/s})t$ to obtain:

$$y(x,t) = \boxed{\frac{0.12\,\text{m}^3}{(2.00\,\text{m})^2 + [x - (10\,\text{m/s})t]^2}}$$

(c) The wave function must be of the form:

$$y(x,t) = f(x + vt) = f[x + (10\,\text{m/s})t]$$

because $v = 10$ m/s

Replace x with $x + (10\,\text{m/s})t$ to obtain:

$$y(x,t) = \boxed{\frac{0.12\,\text{m}^3}{(2.00\,\text{m})^2 + [x + (10\,\text{m/s})t]^2}}$$

Picture the Problem Let the subscript 1 refer to the initial situation–a tension of 800 N and a wavelength of 24 cm. Let the subscript 2 refer to the conditions that the tension is 600 N and the wavelength unknown. We can express the wavelengths of the waves on the wire in terms of the two tensions in the wire and then eliminate the constant frequency by expressing the ratio of the two wavelengths. Finally, we can solve this equation for λ_2.

Express the wavelength in terms of the frequency and speed of the

$$\lambda = \frac{v}{f}$$

wave:

Express the speed of the wave as a function of the tension in the wire:

$$v=\sqrt{\frac{T}{\mu}}$$

Substitute to obtain:

$$\lambda=\frac{1}{f}\sqrt{\frac{T}{\mu}}$$

Express the wavelength when the tension in the wire is 600 N:

$$\lambda_2=\frac{1}{f}\sqrt{\frac{T_2}{\mu}}$$

Express the wavelength when the tension in the wire is 800 N:

$$\lambda_1=\frac{1}{f}\sqrt{\frac{T_1}{\mu}}$$

Divide the first of these equations by the second and solve for λ_2:

$$\lambda_2=\lambda_1\sqrt{\frac{T_2}{T_1}}$$

Substitute numerical values and evaluate λ_2:

$$\lambda_2=(24\,\text{cm})\sqrt{\frac{600\,\text{N}}{800\,\text{N}}}=\boxed{20.8\,\text{cm}}$$

102 •

Picture the Problem Let *m* represent the mass of the rubber tubing whose length is *L*. We can express the travel time for the pulse *t* in terms of the separation of the post and the pulley and its speed. The speed of the pulse, in turn, can be found from the tension in the rubber tubing and its linear density.

Express the time required for the pulse to travel the length of the tubing in terms of its speed and the length of the rubber tubing:

$$t=\frac{L}{v}$$

Relate the speed of the pulses to the tension in the tubing:

$$v=\sqrt{\frac{F}{\mu}}=\sqrt{\frac{F}{m/L}}=\sqrt{\frac{FL}{m}}$$

Substitute for v and simplify to obtain:

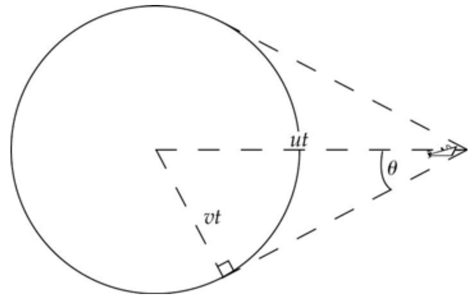
$$t=\sqrt{\frac{Lm}{F}}$$

Substitute numerical values and evaluate t:

$$t=\sqrt{\frac{(10\,\text{m})(0.7\,\text{kg})}{110\,\text{N}}}=\boxed{0.252\,\text{s}}$$

103 •

Picture the Problem The diagram shows the boat traveling on a still lake with a speed v. A bow wave generated a time t earlier is shown at an angle of θ with the direction of the boat's motion. We can use trigonometry to relate the speed of the bow wave to the speed of the boat.



Using the diagram, relate u and v to the angle θ:

$$\sin\theta = \frac{vt}{ut} = \frac{v}{u}$$

Solve for v:

$$v = u\sin\theta$$

Substitute numerical values and evaluate v:

$$v = (10\,\text{m/s})\sin 20° = \boxed{3.42\,\text{m/s}}$$

104 •

Picture the Problem The frequencies and wavelengths of the sound waves are related to the speed of sound through $f = v/\lambda$.

(*a*) Use $f = v/\lambda$ to find f:

$$f = \frac{340\,\text{m/s}}{10(0.3\,\text{m})} = \boxed{113\,\text{Hz}}$$

(*b*) Proceed as in (*a*):

$$f = \frac{340\,\text{m/s}}{0.1(0.3\,\text{m})} = \boxed{11.3\,\text{kHz}}$$

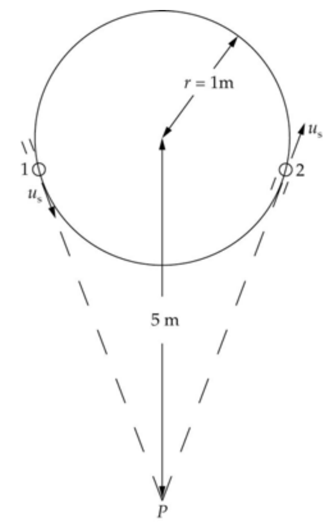
(*c*) Proceed as in (*a*) and (*b*):

$$f = \frac{340\,\text{m/s}}{10(0.06\,\text{m})} = \boxed{567\,\text{Hz}}$$

$$f = \frac{340\,\text{m/s}}{0.1(0.06\,\text{m})} = \boxed{56.7\,\text{kHz}}$$

105 •

Picture the Problem The diagram depicts the whistle traveling in a circular path of radius $r = 1$ m. The stationary listener will hear the maximum frequency when the whistle is at point 1 and the minimum frequency when it is at point 2. These maximum and minimum frequencies are determined by f_0 and the tangential speed $u_s = 2\pi r/T$. We can relate the frequencies heard at point P to the speed of the approaching whistle at point 1 and the speed of the receding whistle at point 2.



Relate the frequency heard at point P to the speed of the approaching whistle at point 1:

$$f_{max} = \frac{1}{1 - u_s/v} f_s$$

Use the relationship between translational velocity and angular velocity to find the speed u_s of the whistle:

$$u_s = r\omega = (1\,\text{m})\left(3\,\frac{\text{rev}}{\text{s}} \times \frac{2\pi\,\text{rad}}{\text{rev}}\right) = 18.85\,\text{m/s}$$

Substitute numerical values and evaluate f_{max}:

$$f_{max} = \frac{1}{1 - \dfrac{18.85\,\text{m/s}}{340\,\text{m/s}}}(500\,\text{Hz}) = \boxed{529\,\text{Hz}}$$

Relate the frequency heard at point P to the speed of the receding whistle at point 2:

$$f_{min} = \frac{1}{1 + u_s/v} f_s$$

Substitute numerical values and evaluate f_{min}:

$$f_{min} = \frac{1}{1 + \dfrac{18.85\,\text{m/s}}{340\,\text{m/s}}}(500\,\text{Hz}) = \boxed{474\,\text{Hz}}$$

106 •

Picture the Problem The crest-to-crest separation of the waves is their wavelength. We can find the frequency of the waves from $v = f\lambda$. When you lift anchor and head out to sea you'll become a moving receiver and we can apply $f_r = \frac{v \pm u_r}{v \pm u_s} f_s$ to calculate the frequency you'll observe.

(*a*) Express the frequency of the ocean waves in terms of their speed and wavelength:

$$f_0 = \frac{v}{\lambda}$$

Substitute numerical values and evaluate f_s:

$$f_0 = \frac{8.9\,\text{m/s}}{15\,\text{m}} = \boxed{0.593\,\text{Hz}}$$

(*b*) Express the frequency of the waves in terms of their speed and the speed of a moving receiver:

$$f_r = (1 + u_r/v) f_s$$

Substitute numerical values and evaluate f_r:

$$f_r = \left(1 + \frac{15\,\text{m/s}}{8.9\,\text{m/s}}\right)(0.593\,\text{Hz}) = \boxed{1.59\,\text{Hz}}$$

107 ••

Picture the Problem Let t be the time of travel of the lefthand pulse and the subscripts L and R refer to the pulse coming from the left and right, respectively. Because the pulse traveling from the right starts later than the pulse from the left, its travel time is $t - \Delta t$, where $\Delta t = 25$ ms. Both pulses travel at the same speed and the sum of the distances they travel is 12 m.

Express the total distance the two pulses travel:

$$d = d_L + d_R = vt + v(t - \Delta t)$$

Solve for vt to obtain:

$$vt = \tfrac{1}{2}(d + v\Delta t)$$

The speed of the pulse is given by:

$$v = \sqrt{\frac{F}{\mu}} = \sqrt{\frac{F}{m/L}}$$

Substitute for v to obtain:

$$vt = \tfrac{1}{2}\left(d + \sqrt{\frac{F}{m/L}}\Delta t\right)$$

Substitute numerical values and evaluate vt:

$$vt = \tfrac{1}{2}\left[12\,\text{m} + \sqrt{\frac{(180\,\text{N})(12\,\text{m})}{0.085\,\text{kg}}}\left(25\times10^{-3}\,\text{s}\right)\right] = \boxed{7.99\,\text{m}}$$

***108 ••**

Picture the Problem Let the frequency of the car's horn be f_s, the frequency you hear as the car approaches f_r, and the frequency you hear as the car recedes f_r'. We can use $f_r = \dfrac{v \pm u_r}{v \pm u_s} f_s$ to express the frequencies heard as the car approaches and recedes and then use these frequencies to express the fractional change in frequency as the car passes you.

Express the fractional change in frequency as the car passes you:

$$\frac{\Delta f}{f_r} = 0.1$$

Relate the frequency heard as the car approaches to the speed of the car:

$$f_r = \frac{1}{1 - u_s/v} f_s$$

Express the frequency heard as the car recedes in terms of the speed of the car:

$$f_r' = \frac{1}{1 + u_s/v} f_s$$

Divide the second of these frequency equations by the first to obtain:

$$\frac{f_r'}{f_r} = \frac{1 - u_s/v}{1 + u_s/v}$$

and

$$\frac{f_r}{f_r} - \frac{f_r'}{f_r} = \frac{\Delta f}{f_r} = 1 - \frac{1 - u_s/v}{1 + u_s/v} = 0.1$$

Solve u_s:

$$u_s = \frac{0.1}{1.9} v$$

Substitute numerical values and evaluate u_s:

$$u_s = \frac{0.1}{1.9}(340\,\text{m/s})$$

$$= 17.89\,\frac{\text{m}}{\text{s}} \times \frac{1\,\text{km}}{10^3} \times \frac{3600\,\text{s}}{\text{h}}$$

$$= \boxed{64.4\,\text{km/h}}$$

109 ••

Picture the Problem The pressure amplitude can be calculated directly from $p_0 = \rho\omega v s_0$, and the intensity from $I = \frac{1}{2}\rho\omega^2 s_0^2 v$. The power radiated is the intensity times the area of the driver.

(*a*) Relate the pressure amplitude to the displacement amplitude, angular frequency, wave velocity, and air density:

$$p_0 = \rho\omega v s_0$$

Substitute numerical values and evaluate p_0:

$$p_0 = \left(1.29\,\text{kg/m}^3\right)\left[2\pi\left(800\,\text{s}^{-1}\right)\right] \times \left(340\,\text{m/s}\right)\left(0.025\times10^{-3}\,\text{m}\right) = \boxed{55.1\,\text{N/m}^2}$$

(*b*) Relate the intensity to these same quantities:

$$I = \tfrac{1}{2}\rho\omega^2 s_0^2 v$$

Substitute numerical values and evaluate I:

$$I = \tfrac{1}{2}\left(1.29\,\text{kg/m}^3\right)\left[2\pi\left(800\,\text{s}^{-1}\right)\right]^2 \times \left(0.025\times10^{-3}\,\text{m}\right)^2\left(340\,\text{m/s}\right) = \boxed{3.46\,\text{W/m}^2}$$

(*c*) Express the power in terms of the intensity and the area of the driver:

$$P = IA = \pi r^2 I$$

Substitute numerical values and evaluate P:

$$P = \pi\left(0.1\,\text{m}\right)^2\left(3.46\,\text{W/m}^2\right) = \boxed{0.109\,\text{W}}$$

110 ••

Picture the Problem The frequency of the sound wave is related to the density of the air, displacement amplitude, and velocity by $I = \frac{1}{2}\rho\omega^2 s_0^2 v$.

Relate the intensity of the sound wave to the density of the air, displacement amplitude, velocity, and angular frequency:

$$I = \tfrac{1}{2}\rho\omega^2 s_0^2 v$$

Solve for the angular frequency:

$$\omega = \frac{1}{s_0}\sqrt{\frac{2I}{\rho v}}$$

Solve for *f*:

$$f = \frac{1}{2\pi s_0}\sqrt{\frac{2I}{\rho v}}$$

Substitute numerical values and evaluate *f*:

$$f = \frac{1}{2\pi(10^{-6}\text{ m})}\sqrt{\frac{2(10^{-2}\text{ W/m}^2)}{(1.29\text{ kg/m}^3)(340\text{ m/s})}} = \boxed{1.07\text{ kHz}}$$

111 ••

Picture the Problem The force exerted on the plate is due to the change in momentum of the water. We can use Newton's 2nd law in the form $F = \Delta p/\Delta t$ to relate F to the mass of water in a length of tube equal to $v_s\Delta t$ and to the speed of the water. This mass of water, in turn, is given by the product of its density and the volume of water in a length of the tube equal to $v_s\Delta t$.

Relate the force exerted on the plate to the change in momentum of the water:

$$F = \frac{\Delta p}{\Delta t} = \frac{\Delta m v_w}{\Delta t}$$

Express Δm in terms of the mass of water in a length of tube equal to $v_s\Delta t$:

$$\Delta m = \rho\Delta V = \rho v_s A\Delta t$$

Substitute to obtain:

$$F = \rho v_s A v_w$$

Substitute numerical values and evaluate F:

$$F = (10^3\text{ kg/m}^3)(1.4\text{ km/s})\left[\pi(0.05\text{ m})^2\right](7\text{ m/s}) = \boxed{77.0\text{ kN}}$$

112 ••

Picture the Problem Let d be the horizontal distance from the soap bubble to the position of the microphone. The angle θ of the shock wave is related to the speed of sound in air u and the speed of the bullet c according to $\sin\theta = u/v$. We can determine θ from the given information and then use this angle to find d.

Express d in terms of the angle of the shock wave and the distance from the soap bubble to the laboratory bench:

$$d = \frac{0.35\text{ m}}{\tan\theta}$$

Relate the speed of the bullet to the angle of the shock-wave cone:

$$\sin\theta = \frac{u}{v}$$

Solve for θ to obtain:

$$\theta = \sin^{-1}\frac{u}{v}$$

Substitute to obtain:

$$d = \frac{0.35\,\text{m}}{\tan\left[\sin^{-1}\frac{u}{v}\right]}$$

Substitute numerical values and evaluate d:

$$d = \frac{0.35\,\text{m}}{\tan\left[\sin^{-1}\left(\frac{u}{1.25u}\right)\right]} = \boxed{26.3\,\text{cm}}$$

113 ••

Picture the Problem The source of the problem is that it takes a finite time for the sound to travel from the front of the line of marchers to the back. We can use the given data to determine the time required for the beat to reach the marchers in the back of the column and then use this time and the speed of sound to find the length of the column.

Express the length of the column in terms of the speed of sound and the time required for the beat to travel the length of the column:

$$L = v\Delta t$$

Calculate the time for the sound to travel the length of the column:

$$\Delta t = \frac{1}{100}\,\text{min} = 0.6\,\text{s}$$

Substitute and evaluate L:

$$L = (340\,\text{m/s})(0.6\,\text{s}) = \boxed{204\,\text{m}}$$

114 ••

Picture the Problem The interval between the arrival times of the echo pulses heard by the bat is the reciprocal of the frequency of the reflected pulses. We can use $f_r = \frac{v \pm u_r}{v \pm u_s} f_s$ to relate the frequency of the reflected pulses to the speed of the bat and the frequency it emits.

Relate the interval between the arrival times of the echo pulses heard by the bat to frequency of the reflected pulses:

$$\Delta t = \frac{1}{f_r}$$

Relate the frequency of the pulses received by the bat to its speed and the frequency it emits:

$$f_r = \frac{1 + u_r/v}{1 - u_s/v} f_s$$

Substitute to obtain:

$$\Delta t = \frac{1 - u_s/v}{(1 + u_r/v) f_s}$$

Substitute numerical values and evaluate Δt:

$$\Delta t = \frac{1 - \dfrac{12\,\text{m/s}}{340\,\text{m/s}}}{\left(1 + \dfrac{12\,\text{m/s}}{340\,\text{m/s}}\right)\left(80\,\text{s}^{-1}\right)} = \boxed{11.6\,\text{ms}}$$

***115** ••

Picture the Problem Let *d* be the distance to the moon, *h* be the height of earth's atmosphere, and *v* be the speed of light in earth's atmosphere. We can express *d* ′*,* the distance measured when the earth's atmosphere is ignored, in terms of the time for a pulse of light to make a round-trip from the earth to the moon and solve this equation for the length of correction *d* ′ − *d*.

Express the roundtrip time for a pulse of light to reach the moon and return:

$$t = t_{\text{earth's atmosphere}} + t_{\text{out of earth's atmosphere}} = 2\frac{h}{v} + 2\frac{d-h}{c}$$

Express the "measured" distance *d* ′ when we do not account for the atmosphere:

$$d' = \frac{1}{2}ct = \frac{1}{2}c\left(2\frac{h}{v} + 2\frac{d-h}{c}\right) = \frac{c}{v}h + d - h$$

Solve for the length of correction *d* ′ − *d*:

$$d' - d = h\left(\frac{c}{v} - 1\right)$$

Substitute numerical values and evaluate *d* ′ − *d*:

$$d' - d = (8\,\text{km})\left(\frac{c}{0.99997c} - 1\right) = \boxed{24.0\,\text{cm}}$$

Remarks: This is larger than the accuracy of the measurements, which is about 3 to 4 cm.

116 ••

Picture the Problem The frequency of the waves on the wire is the same as the frequency of the tuning fork and their period is the reciprocal of the frequency. We can find the speed of the waves from the tension in the wire and its linear density. The wavelength can be determined from the frequency and the speed of the waves and the wave number from its definition. The general form of the wave function for waves on a wire is $y(x,t) = A\sin(kx \pm \omega t)$, so, once we know k and ω, because A is given, we can write a suitable wave function for the waves on this wire. The maximum speed and acceleration of a point on the wire can be found from the angular frequency and amplitude of the waves. Finally, we can use $P_{av} = \frac{1}{2}\mu\omega^2 A^2 v$ to find the average rate at which energy must be supplied to the tuning fork to keep it oscillating with a steady amplitude.

(*a*) The frequency of the waves on the wire is the same as the frequency of the tuning fork:

$$f = \boxed{400\,\text{Hz}}$$

The period of the waves on the wire is the reciprocal of their frequency:

$$T = \frac{1}{f} = \frac{1}{400\,\text{s}^{-1}} = \boxed{2.50\,\text{ms}}$$

(*b*) Relate the speed of the waves to the tension in the wire and its linear density:

$$v = \sqrt{\frac{F}{\mu}} = \sqrt{\frac{1\,\text{kN}}{0.01\,\text{kg/m}}} = \boxed{316\,\text{m/s}}$$

(*c*) Use the relationship between the wavelength, speed and frequency of a wave to find λ:

$$\lambda = \frac{v}{f} = \frac{316\,\text{m/s}}{400\,\text{s}^{-1}} = \boxed{79.0\,\text{cm}}$$

Using its definition, express and evaluate the wave number:

$$k = \frac{2\pi}{\lambda} = \frac{2\pi}{79\times10^{-2}\,\text{m}} = \boxed{7.95\,\text{m}^{-1}}$$

(*d*) Determine the angular frequency of the waves:

$$\omega = 2\pi f = 2\pi\left(400\,\text{s}^{-1}\right) = 2.51\times10^{3}\,\text{s}^{-1}$$

Substitute for A, k, and ω in the general form of the wave function to obtain:

$$y(x,t) = \boxed{(0.50\,\text{mm})\sin\left[\left(7.95\,\text{m}^{-1}\right)x - \left(2.51\times10^{3}\,\text{s}^{-1}\right)t\right]}$$

(*e*) Relate the maximum speed of a point on the wire to the amplitude of the waves and the angular frequency of the tuning fork:

$$\begin{aligned} v_{max} &= A\omega \\ &= \left(0.5\times10^{-3}\,\text{m}\right)\left(2.51\times10^{3}\,\text{s}^{-1}\right) \\ &= \boxed{1.26\,\text{m/s}} \end{aligned}$$

Express the maximum acceleration of a point on the wire in terms of the amplitude of the waves and the angular frequency of the tuning fork:

$$a_{max} = A\omega^2 = (0.5\times10^{-3}\text{ m})(2.51\times10^3\text{ s}^{-1})^2 = \boxed{3.15\times10^3\text{ m/s}^2}$$

(*f*) Express the average power required to keep the tuning fork oscillating at a steady amplitude in terms of the linear density of the wire, the amplitude of its vibrations, and the speed of the waves on the wire:

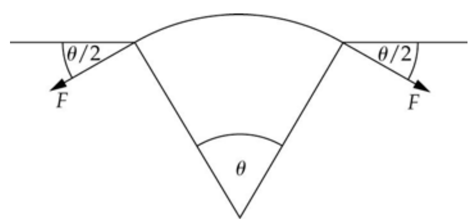
$$P_{av} = \tfrac{1}{2}\mu\omega^2 A^2 v$$

Substitute numerical values and evaluate P_{av}:

$$P_{av} = \tfrac{1}{2}(0.1\text{ kg/m})(2.51\times10^3\text{ s}^{-1})^2(0.5\times10^{-3}\text{ m})^2(316\text{ m/s}) = \boxed{24.9\text{ W}}$$

117 •••

Picture the Problem Because the chain is rolling at high speed we can neglect the effect of gravity. The diagram shows a small portion of the chain. We'll assume that the angle θ is small even though it shown as a large angle in the diagram. Let Δm be the mass of the segment of the chain shown. We'll apply Newton's 2nd law to the segment in order to relate the tension in the chain to its linear density and speed.



(*a*) Apply $\sum F_{radial} = m\frac{v^2}{R}$ to a segment of the chain whose mass is Δm:

$$F_{net} = \Delta m\frac{v_0^2}{R}$$

Express Δm in terms of μ, θ, and R:

$$\Delta m = \mu d\ell = \mu R\theta$$

Express F_{net} in terms of T and θ:

$$F_{net} = 2F\sin\tfrac{1}{2}\theta$$

Substitute to obtain:

$$2F\sin\tfrac{1}{2}\theta = \mu\theta v_0^2$$

Solve for F:

$$F = \frac{\mu\theta v_0^2}{2\sin\frac{1}{2}\theta}$$

Apply the small angle approximation $\sin\frac{1}{2}\theta \approx \frac{1}{2}\theta$:
